I. Let me ask you, for a few moments, to think over that act of last year. It is not meet to call it a "ceremony" or "performance," for those words may have a doubtful meaning. It was a something done, and that with purpose. It was done with reverence and solemnity, and fitting formal circumstance. The like of it has not often been seen in this country. It was simple, but it told of much complex thought and feeling; it was grave, but it was not sad; it was official, but it was not heartless. It was unnecessary, but it was urgent; it was a duty to the remains of Harvey; but it was also an honour to ourselves. Its voice could not "provoke the silent dust," but its tone could stir the now living "ear" and heart, and quicken the still acting brain.

A. One thing that this College did last year was to show [illegible] for the *bodily* remains of Harvey. There was something of him, that neither painting nor bust could be, which we still wished to cherish. It would try to hold together yet longer the last remnants of what was once the medium through which he saw Nature, and by which he read many of her secrets and revealed them. This wish is natural, and old because it is so. If some Eastern nations, in their great reverence for the soul, have taken means to display their contempt for the body, such peoples have been the exception. The Pyramids, the abbeys, the great burial-grounds in town and country, and the world's great surface, scattered over with its complex or simple tombs, all tell the same story of regard for the dust and ashes of those who have gone. Even if the body have been burned, there has been found the urn to hold together the ashes that the flames have not had power to kill. We may know and admit "to what base uses we may return;" but still we resent or recoil from the degradation. There is a widely spread human struggle against allowing the bodies of those we have known and reverenced and loved to merge into the common earth. We set up our barriers against it; we entomb, and we embalm; we carry on a fight—as strong in feeling as it may be futile in effect, but still a real fight—against physical disintegration. This may be all very foolish and unscientific; but still we will, if we can, keep together something of the individual so long as time and outside forces are not too strong for us; and we utter a parable, as we do so, of our regard not only for the bodies, but for the lives of those individual men, as we tell of, or come to know, them, in the thousand biographies that surround us, each one of which is in its very essence "a feeble struggle with death."

The notion that some spark or germ of life might lie hidden in the ashes that were buried or inurned ("lateat scintilla forsan") may have had much to do with the careful keeping of the ashes in the past; but that is not all. Even if Science could quite put out this faint "scintilla," the human Instinct would remain; and would show itself beside almost every open grave, and sometimes display itself in such solemn and remarkable event as that which took place last year at the tomb of Harvey. It was a graceful and an honourable act of this College to take upon itself the work of "Old Mortality"; and to travel away from its ordinary home that it might chisel afresh the marbles that held the remains of its greatest son; but much more than this was accomplished at that time; for therein was shown a profound and still living affection, reverence, and gratitude for Harvey's life.

B. We again to-day would do homage to the *life* of Harvey; looking at it in its threefold aspect of moral, mental, and active energy. We commemorate his character; his rare combination of faculties; and his work achieved. In him there was that due proportion between all those powers which a great thinker of this generation has regarded as the root-fact of what we call "genius."

We like to picture to ourselves what he, now dead in body, resembled when he lived; how he thought; and about what he thought; how and what he did; in what light he regarded his own work; its relation to the work of others; to his ancestors in science, to his immediate predecessors, his associates, his antagonists, and to those who must come after him. This is as natural as is the regard for the bodily remains; but it is on a higher level. Ancient "songs" handed down, in earlier days, the noble deeds, thoughts, words, and characters of those whom it was a religion to venerate, and whose memory it was a bounden duty to prolong. Our short biographies in epitaphs, our longer biographies in books, bear witness to our dislike to the cremation of ideas and of individual life. There is, doubtless, much disintegration and cremation, of a very healthy sort, always going on among the works of the living as well as of the dead; and very small urns might hold all that is worth keeping of the life-work of many. Still even on these we should like to engrave the names. Perhaps in most lives there are many things that those who lived them might gladly see burned away; but, as Sir Thomas Browne says: "We cannot hire oblivion"; and even if "a wise oblivion be a greater good than a strong memory," we still like to preserve the individuality of the really great ones of the earth, and that with all their faults; and we resent—as we do with quite small people—either a flattering, or disparaging, or a one-sided picture.

Reading Harvey's own writings, his theses, their introductions, their dedications, his disquisitions, exercises, letters, and "obiter dicta," we find him writing, all unconsciously, his own biography; and this confers an unspeakable charm upon his works. He does not tell us of his birthplace, or parentage, or where he was taught, or how he lived—which, thanks to many who have written of these things, from Aubrey and Ent to Willis, we know fairly well,—but he reveals his very soul and life, his method of work, and his mode of thinking about it all; as he spent those long years of research, experiment, discovery, and disputation, together with all the toils of a teacher, and the cares of a busy practitioner of medicine.

Thoughts, discoveries, and lives are quickly disintegrated in this fast-moving, restless age, the rate of whose movement shows acceleration every year; and so there is much individual work that must soon pass into, and be lost in, the sum of common knowledge, and become only the groundwork upon which many a superstructure may be raised; but

Digitized by Google

the personality of Harvey can never be lost sight of so long as this College stands, and so long as there are men who care to "read between the lines" of his great works, and find in them the portrait of himself.

It is important, in our attempt to realise this portrait, that we should look, in order to appreciate its value, at the background of the time in which the great artist sketched it.

a. Harvey's work of discovery, like that of all great discoveries, into whatever reach of knowledge and of thought they may have broken, was not unprepared. Men were eagerly looking for a light that they felt sure was coming; and there were streaks of dawn in the Eastern sky that led them to find the Man, and the Truth, for which they had been seeking; so that what before had been mysterious was now clear; what had been dark was now illumined; what they had sought for, now they found.

The contents of the "shell," on the like of which Harvey afterwards wrote so much, were teeming with a growing life, that showed but vague signs upon its smooth, unbroken surface; but Harvey broke the shell and there burst forth at once into a seen life a form and meaning for which all the growing processes within that shell were made. There was a new thing, a new thought, a new generalisation. There was the solution of the problem of yesterday, the answered riddle, the platform for to-morrow's work. All honour to those who, toiling slowly in the night, or in the dawn, with its mist and mystery, have yet made some headway forward and upward, and prepared the path for one among them who has shared their labour, their weariness, their disappointments, and their woes, but who suddenly makes, as it were, a leap to a wider range or to a higher level; and thence holds out the hand of strength and fellowship to place them by his side. We honour the worker, wherever he may be, so long as his labour is honest, and is his best; but we have only scant words to express the regard in which we hold the man whose discerning thought and practised skill have lifted all workmen higher; opened to them new ranges for their toil; given them new methods to follow, and left behind him footprints in which some of them may tread as he goes before them, and passes out of sight.

The peoples in this world have been always fighting, from the days of Cain and Abel until now; but yet there is a book, written not so very long ago, with the title of "The Fifteen Decisive Battles of the World," and perhaps time is yet too young for anyone to say that a sixteenth has been fought. But, in the great conflicts of schools of science, of thought, and of discovery with regard to human life, can we put our finger upon even so many as "fifteen" who have made such marks in history that their works have followed them as "decisive battles" gained? If there be, let us gladly thank all the great heroes who led these fights; but, if we look among them, there is no one whom the gathered-up roll of leaders in the world of thought can show who stands on a higher plane than does our own immortal Harvey.

b. If we would appreciate the value of his work, we must read the writings and become familiar with the beliefs current at his time. We may find their echoes in his replies to his opponents, and see quite plainly that the notions he had to contend with were not even "guesses at truth," but often merely pompous assertions of meaningless nothings—"traditions vainly received,"—but yet held with the cramp-like grasp of drowning men who clutch at straws; and yet uttered with the confidence of those who might be supposed, from the loudness of their cry, to be standing firmly and steadily on solid ground. Those who held them were quite incapable of perceiving that they were empty dogmata, without one particle of substance in their constitution, or one square inch of fact upon which to plant themselves. They seem so nonsensical now that it is almost impossible for us to imagine Harvey caring to reply to them. But in his day they were very real, very vexatious, and very hard to bear. To us they are less than distorted dwarfs; to him they were giants whom he had to fight, and with whom he did wrestle hard. As in the glory of an acknowledged triumph, and in the brilliancy of its reward, we may lose sight of the hard fighting, the heavy blows, the waiting, the misrepresentation by enquiries, and the desertion by his friends, through which the hero passed, as he fought and won; and as he may himself, when he could say with thankfulness and truth "I have fought a good fight," forget, amidst the acclaim of acknowledged victory, the horrors of the battle-field, although the fighting had been very real and the blows were very hard—so Harvey in the lull of opposition seems to have been sometimes at rest and in full enjoyment of the result of his fierce struggle; but while his own conception of the truth was developing day by day and month by month, he struggled hard with the prejudices, the open attacks of jealous competitors, and the scandal of men too dull to originate, too small to think, too dishonest to appreciate, and too weak to yield. When his great discovery saw the day, his soul rejoiced that a new truth was born, and may be he forgot the travail of its birth. But for all that the pain had been very real, and it must have needed all his confidence, all his perseverance, all his energy, and all his patience to have borne the trial without once wincing at the pain

Having said these few things with regard to the preparation made for Harvey by those who had preceded him, and having glanced at the conditions surrounding his active life, let me call your attention to his forethought and instructive prevision of some of the results obtained by the labours of those who followed him.

a. Great men have always foreseen much; or, at all events, have said or seen things of which they perhaps did not and could not fully appreciate the meaning. They have scattered germs of thought around them as they passed, through the varying fields of life, to the point or end that their determination impelled them to attain; and some of these seeds of future discovery have "fallen on good ground, and brought forth fruit." There is here some instance of the process of "evolution" in regard to scientific discovery. Harvey reaped much that he had not sown; but he sowed much more which others, after him, might reap.

The evolution of scientific discovery, which is a matter of simple fact, suggests questions which cannot be discussed on this occasion, but which we may do well to consider.

Is there any spontaneous generation of ideas? Can man never do anything outside the lines in which his forefathers thought and reasoned? Can he originate anything, as by a "sport;" or must all that he can think or know be but the outgrowth of the germ thoughts of others; or the mere learning of details quite far away from what we mean by discovery? There is ancient authority for believing that "there is no new *thing* under the sun;" but has there been no new *thought*? If creative energy be limited in matter, is it also limited in mind? If there has ever been an act of "creation," may not such an act be repeated? May I not further ask if, in the words of the really great men, there are so many fertile seeds, which alone are the germs of all that is to come, may we not, instead of adopting hastily, as we sometimes do, the most charming generalisations of the last few years, and saying, along these lines all thought must run, rather adopt the mood of the great scientific poet of Nature, and feel that "seeing of a thousand seeds, she scarcely brings but one to bear," we join him in his doubt, and "tremble where we firmly stood"?

If it be that Harvey was right, which modern scientific observation has shown that he was not, when he suggested that the force which converted sterility into fertility was one that pervaded the whole body,[1] and might last almost indefinitely, then by analogy we might argue that the thoughts of the great discoverers of all past time may have fertilised the whole race of the thinkers that followed them, and of the thinkers yet unborn; and so "discovery" and "originality" are "surds," for they could have had no beginning. To this it may be replied, The modern appliances of scientific research have shown that in some points Harvey had no means of correcting the dicta of his forerunners by his favourite appeal to Nature. Is it not possible that we are as yet unsupplied with all the *apparatus criticus* for determining whether or no there is such a possibility as an original thought?

b. As a means of estimating the largeness of Harvey's mind and the wide range of his vision, and how much there was that he "saw," but scarcely can be said to have "looked at," let me recall to your notice some of the more interesting of his *previsions*, as forming part of the work of the individual whose memory we meet to-day to cherish.

We find him saying, "In general the first processes of Nature lie hid, as it were, in the depths of night, and by reason of their subtlety escape the keenest reason no less than the most piercing eye."[2] In another paper, "All living things ... derive their origin from a certain primary something or primordium which contains within itself both the

[1] Theory of Conception.

[2] Anatomical Exercises on the Generation of Animals, p. 225.

Digitized by Google

'matter' and the 'efficient cause'; and so is, in fact, the matter out of which, and that by which, whatsoever is produced is made."[3] Again, "It appears advisable to me to look back from the perfect animal, and to inquire by what process it has arisen and grown to maturity, to retrace our steps from the goal to the starting-place; ..... so that we shall perceive from what primary matter and from what efficient principles, and in what way from these, this plastic form proceeds ....."[4] Further on, in the same paper, we find him saying, "Man comes into the world naked and unarmed, ... as if Nature had desired that he should be guided by reason rather than be driven by force; therefore did she endow him with understanding, and furnish him with hands, that he might himself construct what was necessary to his clothing and protection. To those animals to which Nature has given vast strength, she has also presented weapons in harmony with their powers; to those that are not thus vigorous she has given ingenuity, cunning, and singular dexterity in avoiding injury."[5] In connexion with this, he proceeds to mention the "ornaments ..... offensive weapons, teeth, horns, spurs, and other implements employed in combat ..... the subject of dispute being no empty or vainglorious matter, but the perpetuation of the stock in this line or in that; as if Nature intended that he who could best defend himself and his should be preferred to others for the continuance of the kind."[6]

In the passages just read, we have, as it appears to me, very much the same ideas as are now conveyed by the terms "protoplasm"; "the relation of man and animals to their environments"; and the doctrine of "the survival of the fittest."

With reference to the significance of the primordium, the protoplasm, as seen by Harvey, let me read another passage from his writings. Speaking of the lowest forms of life known to him, he says, "These have no heart, as not requiring any impeller of nourishment into the extreme parts; for they have bodies which are connate and homogeneous, and without limbs; so that by contraction and relaxation of the whole body they assume and expel, move and remove the aliment.....The whole is used as a heart, or the whole animal is a heart."[7] Further on, "All local motion proceeds from and has its original in the contraction of some part."[8] Here we have, as it seems to me, an account of the simplest form of life; his counterpart of the "amœba," as we may find it described in the most modern and, to my mind, one of the most able text-books of physiology of our day.[9]

2. Another interesting forecast of Harvey's is found in his pointing to the local variations in blood-supply, as being dependent upon the vessels. He describes the extremities as becoming cold, "the nose and cheeks and hands looking blue;"[10] "the fact that in almost every affection, appetite, hope, or fear, our body suffers, the countenance changes, and the blood appears to course hither and thither. In anger the eyes are fiery and the pupils contracted; in modesty the cheeks are suffused with blushes; in fear, and under a sense of infamy, and of shame, the face is pale, but the ears burn as if for the evil they heard or were to hear."[11] "The blood, he continues, "varies greatly (in its rate of force and movement) according to age, sex, temperament, habit of body, and other contingent circumstances, external as well as internal, natural or non-natural."[12] In another place he says, "We allow to the arteries the same motions which we concede to the heart—viz., a diastole and a systole, or return from the distended to the natural state; this much we believe to be effected by a power inherent in the coats themselves."[13]

The direct object of Harvey in this passage is to show that the heart distends the arteries, and that they collapse by their own contractility; but, taken in conjunction with the other passages that have been quoted, it gives a forecast of what is now of such immense advantage to us—viz., a knowledge of vaso-motor change. He perceived the altered calibre of vessels; he saw this in both contraction and dilatation; he referred this to a power inherent in the coats themselves; he pointed out the relation between these changes and external conditions; also between them and emotional excitement or depression, and yet again, to contingent *internal* circumstances.

A hundred and eighteen years after Harvey published his treatise on the Circulation, Robert Whytt, the President of the Royal College of Physicians in the sister city of Edinburgh, wrote these words: "Some grow pale upon anger; which effect may be owing to a spasm, or continued contraction of the small arteries of the face, by which the motion of the blood will be retarded;" and again, further on, "In blushing, the increased motion of the fluids through the vessels of the face is accompanied with a glow;" and yet again, "The sense of cold and shivering is owing to a spasmodic contraction of these vessels, in consequence of that irritation which the nervous system suffers from the febrile stimulus or the beginning inflammation."[14] Whytt does not discuss the circulation of the blood as described by Harvey, he assumes it as an established dogma; he makes no allusion to any anterior suggestion of change in the calibre of vessels; but he seems, chronologically, to hand down the light of Harvey's torch to these more recent days, in which Claude Bernard, Lister, Brown-Séquard, and others have shown, by their researches, the importance of the knowledge that we now possess of the vaso-motor system of nerves, and its effects upon the function and structure of organs; as well as its relation to the doctrine, diagnosis, and treatment of disease.

3. Another illustration of Harvey's speculation and forecasting of ideas comparatively new to us, but occurring to him as the result of his observations on the mysteries of generation, will have much interest now. "Let physicians cease to wonder [he says] at the manner in which epidemic, contagious, and pestilential diseases scatter their seeds and are propagated to a distance through the air, or by some 'fomes' producing diseases like themselves, in *bodies of a different nature*, and in a hidden fashion *silently multiplying themselves by a kind of generation*, until they become so fatal and with the permission of the Deity spread destruction far and wide among man and beast, since they will find far greater wonders than these taking place daily in the generation of animals."[15] We seem to hear in this sentence the thoughts suggested by the works of Pasteur, Koch, and many others; and while feeling with them, with Seneca (whom Harvey quotes) and with himself that there is truth in saying "agents greater in number and of more efficiency are required in the construction and preservation of an animal than for its destruction .....; yet, following Harvey as he followed Seneca in seeing the analogy between the origin of disease and the process of generation, wonder with him as he exclaims, "How long a time is conception to be carried out to parturition—with what labour and tenderness is an infant reared, ... but by what a nothing is it destroyed? It takes an age to establish cities, an hour to destroy them."[16] Such thoughts may lead us to ask ourselves, in face of the recent calamities in Marseilles, Naples, and Toulon, Do these visitations give sanction to the law of the "survival of the strongest," which was the idea of the generalisation of Harvey, or "survival of the fittest," which was that of Darwin. Man dies, nations become extinct, but the microbe lives on. His earnest cultivators provide him with change of scene, of temperature, of food, and all possible surrounding conditions; and we may almost fancy that we hear the well-tended and well-cultivated tyrant singing, to some ghastly accompaniment:—

> "Men may come, and men may go;
> But I go on for ever."

4. It is difficult to refrain from giving yet another illustration of the mode and degree to which Harvey had forestalled or prepared the way for one of the greatest discoveries since his own time—viz., that of the "reflex action" of the spinal cord. In a letter to Horst, written in 1654–55, he says, looking forward to the work of those who were to follow him, and speaking of himself as "not only far stricken in years, but afflicted with more and more indifferent health ..... I do not doubt but that many things still lie hidden in Democritus's well that are destined to be drawn up into the light by the indefatigable diligence of coming ages."[17]

tween the action of the organs of sense and that of the "sensorium commune," he proceeds to say that there are "some actions and motions the government or direction of which is not dependent on the brain ..... that there is a certain sense or form of touch (meaning contact or impression) which is not referred to the common sensorium, nor in any way communicated to the brain, so that we do not perceive by this sense (i.e., impression) that we feel ..... and this sense we therefore distinguish from the proper animal sense." Harvey termed it a *natural* sense, as distinguished from *animal* sense; and he continues, "such a sense do we observe in zoophytes or plant animals, in sponges, the sensitive plant, &c." Using the word "sense" with this interpretation, he treats of many animals, "who are endowed with both sense and motion without having a common sensorium or brain ..... so also [he adds] do certain natural actions take place in the embryo, and even in ourselves, without the agency of the brain, and a certain sensation takes place without consciousness." After speaking of the difference to be observed between "regulated contractions and relaxations to perform any movement, such as progression or prehension," he compares these movements to "the muscles or organs of motion, when affected with spasms or convulsions from an irritating cause," and points out their resemblance to those of "the decapitated cock or hen.....the convulsive movements of the legs and wings, but all confused and without a purpose, because the controlling power of the brain has been taken away."

The explanation of these movements given by Harvey—viz., that they "proceed from the power of the heart, and depend on it," is certainly not true in the sense in which he intended it, but he gives a most interesting illustration of his physiological insight when he says, "We have an excellent example of both these kinds of motion (animal and natural) in respiration. For the lungs, like the heart, are continually carried upwards and downwards by a natural (i.e., unconscious and involuntary) movement, and are excited by any irritation to coughing and more frequent action; but they cannot form and regulate the voice, nor can singing be executed without the assistance, and in some sort command, of the sensorium commune."[18]

In another paper Harvey gives an interesting account of parturition in a "young woman ..... in a profound state of coma, ... but in whom the application of a powerful sternutatory ..... excited convulsions throughout the body, beginning at the shoulders and gradually descending to the lower extremities. As often as the stimulus was applied the labour advanced ..... until the child was born, without the consciousness of the mother, who still remained in a state of coma."[19]

A hundred years after these words were written, Unzer developed the idea still further, in his Treatise on "Animal Nature in Relation to purely Animal Forces, or Vis Nervosa"; and after him Prochaska, in his "Dissertation on the Functions of the Nervous system," defined accurately the limits of the reflective centre; but it was left for Sir Charles Bell, and much more to our own distinguished Fellow, Marshall Hall, to expound the meaning of these movements; to comprehend and reveal the physiology and pathology of action in the spinal cord; to apply this knowledge to the explanation of many diseases, and to devise means for their control or cure. In doing this, he again prepared the way for later researches upon the reflex function, as it affects "local" circulation, and so render possible a knowledge of many of the finest points of neural and vascular action, which we, directly, owe to the labours of those great workers to whom allusion has already been made, when dealing with Harvey's foresight of that matter. Again, in the passage quoted from the paper on Parturition, we find a curious forecasting of the ingenious application of the reflex theory of Hall to the interpretation of the action of the uterus which was made by Dr. Tyler Smith.

In thus sketching some of the motives which led to the event of last year, and also to the fact of our meeting here to-day, it has been my wish to show that we still hold in reverential regard the perishing remains at Hempstead; and also the living force that is with us, now and here; and which comes to us from our knowledge of the individual, Harvey, in his relation to the past, the surrounding conditions of his time, and his outlook towards the future.

C. There is one thing more, however, that this College has done for many years, and that is, by this annual Oration, to *hand down* to coming generations the memory of him from whom we have learned so much, and to whom our debt of gratitude is larger than we, perhaps, as yet can know; certainly much larger than it falls within the range of my powers to express.

We speak of the "immortal Harvey," but in what sense? To many, his own words would convey all the meaning of that attribute. "The eternity of things," he says, "is connected with the reciprocal interchange of generation and decay; and as the sun, now in the east, and then in the west, completes the measure of time by his ceaseless revolutions, so are the fleeting things of mortal existence made eternal through incessant change; and kinds and species are perpetuated, though individuals die."[20] True, grandly but sadly true, and yet our meeting of this day is a declaration that such truth is not universal. Much of his work has become a part of common knowledge; and so will live on in the lives of those who are the "interpreters of Nature," so long as Nature lasts. But the wish that animates us to-day is to hand down to those who follow us some knowledge of the individual to whose life we owe so much, and whose personality we would not "willingly let die." There are many ways in which this may be done, but I will allude to only two.

1. The *names* of some great men have been associated with the discoveries that they have made; and they perhaps are used, many of them, in such familiar way that they convey little or no suggestion of their meaning. In some generation or two yet to come may it not be that the etymology of such words as Fallopian tube, Meckel's ganglion, Bright's disease, Addison's disease, Corrigan's pulse, galvanism, faradaism, an ohm or a volt will have become somewhat obscure? Or if the meaning of such phrases may be found in lexicons, are there many who will try to find out those meanings? It seems to me probable that individuality will not be maintained by such means; and that future students may sometimes be disposed to ask—as I once heard the question put quite seriously—whether or no the "portal vein" was not named after the distinguished French physician Portal!

While the progress of science is constructive of generalisation and so-called "laws," it is destructive, as Harvey says, of the individual life; but yet we give "names" to organs, functions, forces, and shrewd connotations of phenomena, in order—while finding them convenient at the time—to delay, if not arrest, the disintegration of the work of those men whose names we thus hand down to those who follow us.

Do we not think it probable that, as future research proceeds, some of these names, which have passed into many countries and many tongues, may be lost sight of, and be so decomposed that they pass out of common use?

At this hour, and still in the lifetime of our honoured President—whom may God long preserve!—the phrase "continued fever" has passed into practical disuse; and this has been due mainly, if not exclusively, to the industry and genius which led him to disintegrate the name, trace out the causes, and define the maladies that had long passed under that common term.

2. Again, there are certain *days* by which the memory of great men is perpetuated. From very olden times until now; and from the far East to the far West, "days" are set apart for the purpose of recalling individual lives. Ceremonies, of all kinds, have been parts of these human, national, and instinctive acts. They begin in the smallest families with the "birthdays," and they stretch out to the acts of the greatest nations.

This is St. Luke's Day in the calendar of millions, but there are days still set apart compared in antiquity with which the observance of St. Luke's Day is but a modern event. Two hundred and eighty years have passed since Harvey was a member of this College; for two hundred and fifty-six years his great work ("De Motu Cordis et Sanguinis") has been before the world; two hundred and twenty-seven years have elapsed since he was buried in the quiet little church of Hempstead. And yet, only one year has passed since this College removed his remains still "lapt in lead" from the vault in which they had lain so long, and placed them in the safer keeping of new and carefully selected marble.

With us, although it is not so named, this is "Harvey's Day," and three hundred years have passed since he was born. How long this commemoration will continue we

[18] On Generation, p. 432, *et seq.*

Digitized by Google

cannot tell. Our knowledge of the future, if we have any, is but scant. Who knows whether, when another sixty-nine years have passed, "Waterloo Day" will be kept in memory of Wellington?

No one can answer us in our questions. But this we may do; we may look to the past, and learn its lessons; we may look to humanity, and read its instincts; we may read the record of this College, and know its feeling; and of this we may be sure, that, although Harvey's name may be unknown to many in the days to come, yet so long as disease lasts, so long as the movements of the blood form part of the study of the physiologist and the art of the physician; so long as any further light is to be thrown upon them by cardiograph or sphygmograph, or by any as yet unthought-of method of investigation—so long as "the circulation" is a recognised fact of science, his work will live; and although much of it may lie hidden in the common notions of the future, yet the life of Harvey will be maintained in its integrity by the future Fellows of this College, and the greatness of his character will be brought again and again to light by many who will, more adequately than I can do, discharge the duties of this day.

It has been my wish, in what has hitherto been said, to lay before you some explanation of the motives that bring us together now; and also of those that led this College, last year, to the grave of Harvey. But further.

II. If we would now appreciate the work of Harvey, let us for a moment try to eliminate from our knowledge the fact of "the circulation of the blood," and then imagine ourselves to be face to face with the diseases that we are daily treating; with fever, apoplexy—hæmorrhagic, embolic, or diathetic; with dropsy, with cardiac disease, recent or old; with degeneration of structure, or with functional derangement. It requires some force of fancy to realise what would be our position. The thermometer might teach us much; but it is difficult to see in what way either stethoscope, cardiograph, or sphygmograph could do other than augment our bewilderment. Those who have made out for us the meaning of the cardiac sounds; those who have skilfully constructed apparatus so as to make the heart itself record, in some fashion, its own marvellous movements; and those who have delineated, in some sense, the curve and time-ordered elements of the radial pulse, would all admit that their work was based upon this foregone conclusion, the accepted fact that the blood moved onwards in a circle. They have attained to knowledge that Harvey could not reach; but let me ask could they have known what they now do unless Harvey had raised the platform upon which they stood? "The thoughts of men are widened with the process of the suns;" and, by slow degrees, others might have done the work, or made the discovery, that he made; but the effect of his energy was a grand upheaval of the crusted surface of the past; a Titanic throe that brought to the birth a new and mighty force and fact; and, when some of the dust and boulders had been cleared away, placed all who followed him on a higher plane, and in a clearer light. It is given to the few great men to save the time and labour of the many. They not only take strides that would be impossible for those of lesser build, but they carry with them, over the bridge that they have thrown across the great gulf between the question of yesterday and the answer of to-day, all those who have eyes to see, ears to hear, and hearts to follow.

III. Next, let me bring before your notice some of the main features of Harvey's "character," as this displays itself in his written "work." Chronologically, his character must precede his work; but the former was developed by the latter. These things act and react; moral forces become greater as our toil grows harder; and, in so doing, give not only fresh impulse, but increased strength for work.

Throughout Harvey's writings there is an eminently religious tone; a devout and reverential recognition of God; not only as the great primal, ever-acting force, behind, outside, and before all the works of Nature; but as the Being, "the Almighty and Eternal God," to whom, as he says in his last will and testament, "I doe most humbly render my soule (as to) Him that gave it; and to my blessed Lord and Saviour Jesus Christ."[21]

But Harvey did not let his religious convictions hold him in the tight grasp of what has been termed the "theologic stage" of development; nothing prevented him from seeing all that he could see, and frankly telling all that he believed; and so we find him spurning some of the figments about "the spirits ..... of a sublime, lucid, ethereal, celestial, or divine nature," when they are employed to fill up gaps in the physiology of his day; and comparing those who use them to "the vulgar and unlettered, who, when they do not comprehend the causes of various effects, refer them to the immediate interposition of the Deity."[22]

Harvey, although saying that "the Divine mind of the Eternal Creator which is impressed on all things creates the image of itself in human conceptions;"[23] and, again, that all the arts are but imitations of Nature.....as our reason or understanding is a derivative from the divine intelligence manifested in his works;" and still further to affirm as follows—"wherefore, according to my opinion, he takes the right and pious view of the matter, who derives all generation from the same eternal and omnipotent Deity, on whose nod the universe itself depends;" yet shows his freedom from theologic dogma, and his wide range of thought in adding, "Nor do we think that we are greatly to dispute about the name by which this first agent is to be called or worshipped; whether it be God, Nature, or the soul of the universe—whatever the name employed—all still intend by it, that which is the beginning and the end of all things; which exists from eternity and is almighty; which is author or Creator, and, by means of changing generations, the preserver and perpetuator of the fleeting things of mortal life; which is omnipresent, not less in the single and several operations of natural things than in the infinite universe."[24] We are reminded by this passage of the well-known dialogue, in which Faust, replying to Margaret's examination of his creed, says—

> "Call it whate'er thou wilt—heart, love, or God,
> Or happiness!—I cannot give it name."

And the fair Margaret makes answer—

> "All that is very good and true;
> Nearly the same the Priest says too,
> Only in somewhat other words than you."

But Harvey recurs to the same theme, and after saying that "the most perfect man, whose highest excellence is that he knows himself," adds, "we ourselves, as is seeming in these days (hold) as the Almighty first cause of all things ..... the Creator and Father of all that is in heaven and earth, on whom animals depend for their being, and at whose will and pleasure all things are and were engendered."[25]

"It is true," said he, in conversation with Dr. Eut, "the examination of the bodies of animals has always been my delight; and I have thought that thence we might not only obtain an insight into the lighter (? higher) mysteries of Nature, but there perceive a kind of image or reflex of the omnipotent Creator himself."[26]

If Harvey, though a devout believer in God, was yet free from all the restraints of the so-called "theologic stage"; he also, although a learned and keen metaphysician, had escaped from the trammels of what has been termed the "metaphysic stage." He had "cast them off with as much ease as Samson his green withes." He meets the metaphysician on his own ground with clever dialectic; but he pours contempt on those "who advocate incorporeal spirits, having no ground of experience to stand upon;" adding that "their spirits are indeed synonymous with powers or faculties, such as a concoctive spirit, a chylopoietic, &c., they admit as many spirits as there are faculties or organs." And, before this, with regard to the nature of "the spirits," he says, "There are so many and such conflicting opinions, that it is not wonderful that the spirits whose nature is thus left so wholly ambiguous should serve as the common subterfuge of ignorance. Persons of limited information, when they are at a loss to assign a cause for anything, very commonly reply that it is done by the spirits; and so they bring the spirits into play upon all occasions; even as indifferent poets are always thrusting the gods upon the stage as a means of unravelling the plot, and bringing about the catastrophe."[27]

If it be asked what was, then, Harvey's position, and what was the method he employed? my reply is that he, being one of "the freemen whom the truth makes free," held the position of an observer, a questioner, and interpreter of Nature. In the letter by which he dedicates to the President and Fellows of this College his "Anatomical Disquisition on the Motion of the Heart and Blood in

Animals," he declares himself "the partisan of truth alone."[28] And throughout all his writings that follow he never swerved from the position he had taken. To him "virtue," as it has been well said by Emerson, "lay in the adherence in action to the nature of things, and the nature of things made it prevail."

The intense love that Harvey felt for Nature led him to choose her as his constant companion, and his guide in the search for truth. There was nothing that she could show him that was too great for him to attempt to understand; nothing too small for him to pass by, or to regard with other feelings than those of affection, of reverence and wonder. The teaching of Nature was to him absolute in its authority. "The facts cognisable by the senses," he say, "wait upon no opinions, ... the works of Nature bow to no antiquity; for indeed there is nothing either more ancient or of higher authority than Nature."[29] Harvey "observed" the facts before him, and he had eyes to see; but not content with the "experiments prepared by Nature," he "made" new facts by his skilful manipulation of the materials that were lying at his hand; and thus he asked pertinent questions, and obtained their answers. He thought about all these things; he reasoned upon them all; he sought and found all the help that metaphysical method and learning of the schools could render him; and, then, he became their "interpreter."

His mode of progression may be defined as "longitudinarian" (if I may use the word, coined some years ago in opposition to one very familiar to us all)—i.e., he looked and worked straight from end to the end. His line was the shortest one that he could draw between the simplest, the first, fact observed and the most remote object of his gaze. He thought in "a straight line;" he never swerved in his forward march; but, as he passed onwards, he saw things outlying on by-paths, but his own force of movement dragged them into his own well-chosen course, and he made them help him on his way. Arrived at his goal, he arranged his materials with care, and proceeded to explain their meaning by a simple inductive process. But, still keeping the same point in view, he approached it from other sides. Sometimes his lines, although converging, did not meet at the point he quite expected. Here his power of thinking outside of and beyond the facts came to help him; he made new observations, new experiments, and at last focused them on a point made bright by the rays of his own genius. Dr. Ent spoke but the truth when he said to the President and Fellows of this College, "Our Harvey rather seems as though discovery were natural to him—a thing of ease, and of course, a matter of ordinary business; though he may nevertheless have expended infinite labour and study on his works."[30]

Harvey made use of working hypotheses; but he never confounded them with either facts, inductions, or laws. He claimed in one of his ingenious theses the liberty which he willingly yielded to others, "to put forward as true (in matters full of obscurity) such things as appear to be probable until proved to be manifestly false;"[31] and after demolishing many theories of others, "prayed for a place" for his own "conjecture until something certain should be established in the matter."[32]

If some fact, apparently opposed to a truth that Harvey believed himself to have established, confronted him in his way, he rode over it, with a force that could only come from the momentum that his strong conviction had given to his movement onwards. For example, he says, "There is one experiment which I would have everyone try who is anxious for truth, and by which it is clearly shown that the arterial pulse is owing to the impulse of the blood. Let a portion of dried intestine..... be taken and filled with water, and then secured at both ends like a sausage: by tapping with the finger at one extremity, you will immediately feel a pulse and vibration in any other part to which you apply the fingers, as you do when you feel the pulse at the wrist." After referring to the manner in which such percussion may be made of use in distinguishing between air and fluid in the abdomen, he continues, "Having brought forward this experiment I may observe that a most formidable objection to the circulation of the blood rises out of it, which, however, has neither been observed nor adduced by anyone who has written against me;" and then he falls back upon his observations which show that, in spite of this seeming difficulty, the circulation has been proved. He says that he had "already satisfactorily replied to this difficulty;" and such is true, inasmuch as he had pointed out that all the blood did not pass through the vessels, but that some of it was detained for nutrition; he had spoken of the contractility of the arteries, and of the impulse wave; but his solution of the difficulty, that he himself alone had seen, was founded on his confidence in the truth of his main assertion.

Boldness was a great feature of Harvey's character when he told any of the truths he knew. "It were," he says, "disgraceful ..... with this most spacious and admirable realm of Nature before us ..... did we take the reports of others upon trust. ..... Nature is herself to be addressed; and the paths she shows us are to be boldly trodden. ....."[33] And again, at a later period, he writes: "The doctrines inculcated on the subject of the humours, and which, as being entertained by the ancients, Fabricius regards as certain truths, requiring no further proofs, are inconsistent and false."[34]

But Harvey, although bold and strong, was meek, cautious, and polite. He preferred "being wise with the few ..... to going wrong with the many."[35] Dr. Ent, in conversation with Harvey, said to him: "You yourself, I well remember, informed me once that you had never dissected any animal—and many and many a one you examined—but that you discovered something unexpected, something of which you were formerly uninformed."[36] He was "greatly afraid lest he might be charged with presumption, did he lay his work before the public at home or send it beyond seas for impression ..... unless (as he says) I had first proposed its subject to you (the President and Fellows of this College), and had confirmed its conclusions by ocular demonstrations in your presence, had replied to your doubts and objections, and secured the assent and support of our distinguished President."[37] Perhaps it might be well if a similar submission were sometimes adopted in this nineteenth century. But so much has been added to what is called our scientific literature during the third quarter of this century, and its now current fourth, that, perhaps, no officer of the College will thank me for the suggestion.

Harvey fully realised the value to be attached to the "conclusions to which others had come who had looked" at facts for themselves; but he adds, "he who truly desires to be informed ..... must be held bound to *look for himself* ..... for it is our duty to approve or disapprove, to receive or reject, everything only after the most careful examination.....to examine, to test whether anything has been well or ill advanced, to ascertain whether some falsehood does not lurk under a proposition.....it is imperative on us to bring it to the proof of such, and to admit it or reject it on the decision of such."[38]

In much of his writing, Harvey was both humorous and eloquent, and he could exhibit high indignation when he dealt with his detractors, yet "to return evil speaking with evil speaking" he held to be unworthy in a philosopher and a searcher after truth." The passage, however, that follows this, shows that Harvey could (as Sir Anthony Absolute did), if he were tempted to do so, use "strong language"; for he comforts Riolanus by assuring him that "it cannot be helped that dogs bark, and vomit their foul stomachs, or that cynics should be numbered among philosophers; but care must be taken that they do not bite or inoculate their mad humour, or with their dog's teeth gnaw the bones and foundations of truth;"[39] but we must remember that this was not said *to* his detractors, but only *of* them, said to his friend Riolanus, and moreover it was said in Latin, and that makes all the difference.

But, with the exception of a few scattered passages of just wrath, Harvey was always dignified, lenient, and calm. He was, as his contemporary Ent said of him, "beyond all praise," and it may be justly repeated of him, when regarding the strength and gentleness of his great heart:—

> "He has outscored the shadow of our night,
> Envy and calumny, and hate and pain,
> And that unrest which men miscall delight
> Can touch him not and torture not again."

He acquired Fame, which certainly was not to him "the spur" that might his

> "clear spirit raise
> To scorn delights and live laborious days."

It may be, as was said of others in his day, that it was "the last infirmity of noble minds," but it was not so with our illustrious Harvey. "Think me not eager," he says in one of his Introductory Letters,[40] "for vainglorious fame, rather than anxious to lay before you observations that are true, and that are derived immediately from the nature of things." Truth was what he sought, and what he found; and if Fame went with him, and followed him to his grave, and waits upon him now, there was no seeking for it on his part; nor could he well have imagined, with all his force of fancy, such a tribute to his memory as that of last year in the churchyard of Hempstead.

Harvey's great achievements were the result of his method—viz., that of observation and experiment. Nature "displays" much; "the heavens declare the glory of God," and she is always "revealing" as she moves, and she is never still; but Nature is ever moving "onwards" to some unknown goal, and at each onward step she, while revealing, "hides," leaves behind in her wake something of the past, which now we cannot see, and presents new facts and new combinations for man—one of her factors—to interpret.

Harvey was one of her keenest and most devout interpreters. To him, as he stood by and listened, the Nature-spirit sang, and with profoundest meaning,

"So work I at Time's rushing loom,
And weave the living robe of God."

In reverence Harvey knelt before her; but not satisfied with what he saw and heard, he asked her *questions*—and this, with no notion of confusing her, or misreading what she had already said or written,—for he was just the kind of questioner to ask the kind of question to which she readily gave answer. He examined her "in chief" to find out the *right*; he "cross-examined" her, but in no unfriendly tone, to bring her answer to a "yes" or "no," and so disprove the *wrong*, the untruth which other questioners had placed in evidence. "Nature," said he to Ent, "is the best and most faithful interpreter of her own secrets; and what she presents either more briefly or obscurely in one department, that she explains more fully and clearly in another. ..... Truth," he continues, "scarce wants an advocate."[41] Nature to him was a perfect verity: the one witness that could never be abashed or shaken; the one witness in whom there could be no false way; the one witness who could not lie. There was no need to put her "on her oath," for she, in her prime, had been adjured, by the Most High God, to tell "the truth, and nothing but the truth." This she has always done, and now is doing, and will, as we believe, go on to do.

But can she tell "the whole truth?" Will Nature ever tell or teach us this? I cannot presume to answer the question which yet I dare to ask; but my own conviction is that she neither will nor can do this thing until the last hour of Time has struck, and has ushered in the dawn of that one, long, clear, eternal day, whose "sun shall no more go down," and in whose ever-growing light we may hail the presence of that

"far-off Divine event,
To which the whole creation moves."

SANITATION IN SHOREDITCH.—At the meeting of the Shoreditch Vestry on the 15th inst. the sanitary state of six houses, owned by a prominent member of the Hackney Vestry and District Board of Works, was discussed. The sanitary officer presented a statement, in which he said that the houses had been periodically flooded with sewage in the basements for eight years; that repeated notices (nine in number) had been served without avail; and that fourteen letters had been addressed to the owner, several of them expressing the utmost dissatisfaction with his work. In defence, the owner contended that he had done nine-tenths of the work required, and, after a brief but excited debate, the Vestry adjourned without adopting the committee's report.

THE winter course of lectures at the Parkes Museum will commence on Thursday, Nov. 13th, when Mr. G. J. Symons, F.R.S., will give an address on the Relation of Meteorology to Hygiene. On November 27th Dr. Alfred Carpenter will speak on Progress and Co-operation in Sanitary Work. Other lectures will be given by Sir Spencer Wells, Bart., Mr. Shirley Murphy, Mr. Cantlie, and Dr. Crichton Browne.

An Address
ON
CORROSIVE SUBLIMATE AS A SURGICAL DRESSING.

Delivered at the opening Meeting of the Medical Society of London, October 20th, 1884.

BY SIR JOSEPH LISTER, BART., F.R.S.,
PROFESSOR OF CLINICAL SURGERY IN KING'S COLLEGE.

MR. PRESIDENT AND GENTLEMEN,—When, in an address delivered at the opening meeting of last session, I expressed myself in what some of my hearers regarded as terms of overweening confidence in the trustworthiness of antiseptic treatment, I little thought that, a year later, I should have to tell you of failures on my own part; yet such is the case. Several instances have occurred, within the last few weeks, of results deviating from our typical experience in antiseptic treatment, such as I was in no way prepared to meet with, and in one case a fatal event ensued. A lady, on whom I operated for scirrhus of the mamma, with removal of the axillary glands, died of a spurious pyæmia, or a variety of septicæmia, an occurrence such as I have not met with for many years past. We dressed the wound in the usual way. Two days after the operation there was pus already present at the anterior part of the incision. There happened to have been an unusual flow of blood at this part, where we do not as a rule expect much. It is a very unusual thing for pus to appear so early. We used to say, in what I may term the pre-antiseptic days, that, if we operated upon sound tissues, suppuration occurred, provided primary union did not take place, in from three to four days, three days in children, four days in adults, and, perhaps, in warm weather, rather earlier than four days. For pus to occur to the amount of several drachms at the end of two days was therefore very unusual, and some special form of organism, I have no doubt, was present. Micrococci were indeed found after death in abscesses which had formed within the pleura. Nevertheless, though I believe some unusual organism was present, we have been accustomed to consider ourselves free from the apprehension of such ill effects; and though no other fatal case occurred, I am thankful to say, there have been several instances of deviation from the typical course, where, instead of union without suppuration at all, we have had healing retarded by the formation of more or less pus, undoubtedly of a septic character—in the sense in which we now use the term septic—that is to say, dependent upon the development of micro-organisms, although no smell was perceptible. Now, Sir, I need hardly say that one such result as that to which I have referred, a fatal event under circumstances which we have been accustomed to consider absolutely free from danger, made me reflect most seriously; and the other cases, though less disastrous, were also grave cause for reflection.

In looking for the source of our misfortunes, it was to the external dressing that we naturally turned our attention. The experiences of Mr. Cheyne and Professor Ogston indicate pretty distinctly that the means which we ordinarily use are sufficient for the purpose of rendering our wounds free from mischievous micro-organisms at the time we put on our dressings. Both Mr. Cheyne and Professor Ogston have found, by using the most advanced methods of investigation, that if a carbolic acid gauze dressing is changed daily, no organisms are met with in the discharges. That, I say, seems pretty conclusive evidence that the means which we have adopted hitherto for the purpose of keeping our wounds pure, up to the time when the dressings are applied, are sufficient. With regard to our external dressings, our suspicions tended to turn upon the eucalyptus gauze. Eucalyptus oil is undoubtedly a powerful antiseptic, and I have been using it in the form of gauze for a considerable time past. One difficulty with it is its great volatility. In the first instance I employed gum dammar, instead of common resin, in the manufacture of the gauze, because I found that gum dammar held the eucalyptus oil more securely

Digitized by Google

than the resin does; but gum dammar is an expensive gum, and, after some trials with common resin, I thought I was justified in substituting the cheaper material, and for a while we seemed to get good results with this arrangement. But, as I have already said, more recently the results were not satisfactory. I mean that, now and again, a case occurred which was unsatisfactory. On making inquiry of the manufacturer of our eucalyptus gauze, I found that he had deviated from the instructions which he had received as to the manufacture; that he often left the gauze, for a considerable time after it had been charged, exposed in the air before folding it up, thus affording opportunity for the escape of the volatile constituent in large amount; and in hot weather, such as that during our recent summer, this was more especially apt to occur. We found, as a matter of fact, that the eucalyptus gauze supplied to us had not the softness which it ought to have, caused by the adequate amount of eucalyptus oil. I was thus led to attribute our disasters to imperfection in the manufacture of the eucalyptus gauze.

These circumstances led to a reconsideration of the subject and to an appreciation afresh of the disadvantages of any volatile antiseptic substance. Volatile antiseptics have their own advantages, to which I need not refer, but they have great disadvantages. In the first place, we are at the mercy of our manufacturer. The resin and paraffin so glue the folds of the gauze together, if it is allowed to cool in mass, that it must be opened up while warm, and upon the way in which this is done by the manufacturer much depends as to the quantity of the antiseptic present in the gauze. In the next place a volatile antiseptic, such as either carbolic acid or eucalyptus, has the disadvantage that it requires careful treatment by the surgeon himself. The material containing it must be kept in well-closed metallic vessels; otherwise evaporation soon impairs its qualities. And, in the third place, there is this disadvantage attending all volatile antiseptics, that the longer the dressing is kept upon the body the less efficacious does it become; and who is to say when the time arrives when it has become so inefficacious that it is necessary to remove it? I have been accustomed to regard a week as the limit of the time during which a carbolic acid gauze dressing may be regarded as effectual; but beyond the fact that, with this period, our results were, on the whole, satisfactory, we had no precise grounds to go upon. In that respect a volatile antiseptic must always be at a disadvantage, as compared with a non-volatile one, which will be just as efficacious at the end of a month, or six weeks, as it is when first applied, provided it is not soaked with the discharge.

Salicylic acid is a non-volatile antiseptic; but salicylic acid, as I ascertained from experiments several years ago, is very far from being as powerful in antiseptic qualities as carbolic acid, and therefore I have never ventured to use it for serious cases. Iodoform, while volatile, is very slowly volatile, and, at the same time, so little soluble in the discharges, that in these points of view it seems an admirable antiseptic; but iodoform is by no means a potent agent in its action on micro-organisms. I ascertained some years ago, for example, that, taking a 10 per cent. iodoform wool, the strongest used, and soaking this with milk, the lactic fermentation was only a short time retarded, and in the course of a few days, not only the *bacterium lactis*, but multitudes of other kinds of bacteria were seen, in abundance, in the milk. Again, uncontaminated urine being made to soak such a piece of wool, and then inoculated with putrefying urine, I found that the ammoniacal fermentation was only a short time retarded by the iodoform. Hence I was not surprised to learn that in the practice of Schede of Hamburgh, and others, it had been found that erysipelas occurred under the iodoform dressings. It is remarkable that iodoform has such an effect as it has in preventing putrefaction, but it is by no means a powerful germicide.

But there is another non-volatile antiseptic, corrosive sublimate, to which attention has been more especially directed of late years by Dr. Koch; and here I may be permitted to give my tribute of praise to the admirably conceived and conclusive experiments which he has performed upon this subject. Koch proceeds in this sort of way: he dips a very small piece of silk thread into a fluid containing the spores of the bacillus anthracis, known to be highly resisting to the various agencies inimical to low organisms. After this silk thread has become dry he dips it in the antiseptic solution to be tested, keeping it there for a minute, half a minute, five minutes, or any length of time that is required. He then, by means of water or alcohol, or some fluid known not to influence the vitality of the spores, washes away the antiseptic from the thread, and brings into play his beautiful method of solid culture-material. He places the little bit of silk thread upon a piece of gelatine properly provided with nutritious material, and of course scrupulously pure, and observes, by means of the microscope, whether the spores in the silk thread develop or not. He ascertained by experiments of this character that a solution of only one part of corrosive sublimate in 20,000 parts of water was amply adequate absolutely to destroy the vitality of the spores of the bacillus anthracis, about the most resisting spores that are known. But he found also that as weak a solution as 1 of the sublimate to 300,000 parts of a solution of extract of meat was sufficient to prevent the development of the spores so long as they remained in it; but when the silk thread, having been for any length of time in this exceedingly weak solution, was withdrawn from it, washed, and then placed upon the nutritious gelatine, development occurred as if the spores had not been exposed at all to any injurious agency; and thus Koch established in a most definite manner the distinction, and a very important one it is, between two different effects of antiseptic agents—one, the action by which the vitality of organisms is destroyed; and the other, that by which development is simply arrested, or prevented temporarily from occurring, without the vitality of the spores being interfered with. The former we may term "germicidal action." For the latter, it is somewhat difficult to find a good English term. I happened, I believe, to be the first to use the word "inhibitory" in English physiology, by the advice of my old friend, Dr. Sharpey, with reference to an early paper I was about to publish on what the Germans term the Hemmungs Nerven-System; and as this same word Hemmung is used by the Germans for this checking or suspending action of antiseptics, without destruction of vitality, and as it is very important that we should have some term which distinguishes the one action from the other, I may venture to employ this same word "inhibitory"—a good old English word—for this action of antiseptics, and to speak of their "inhibitory action" as distinguished from their "germicidal action."

Now, these properties of corrosive sublimate were such as no other antiseptic agent had ever been ascertained to possess in anything like such dilute solutions. With regard to our purposes in antiseptic surgery, the inhibitory action of the antiseptic would be sufficient, provided we were satisfied that our wound is left free from injurious organisms, and that the dressing which we apply, itself contains no such organisms still alive. Then, all we require is that the dressing should be able to prevent the development of organisms from without into the discharges with which the dressing may be soaked. That is obvious.

Corrosive sublimate has been used extensively already by our German brethren, chiefly in the form of sublimate wood-wool, as it is called, in which ½ per cent. of corrosive sublimate, with an equal part of glycerine, is mixed with what is termed "wood-wool"—namely, pinewood reduced almost to a state of powder by suitable machinery. This is highly absorbent. It is employed in large masses, and, so used, has given many excellent results. At the same time, it is somewhat unwieldy in its application. Under certain circumstances it is not convenient to have so large a mass as is essential for its safety, and we have also varying reports as to its efficacy; and I may remark that we find some surgeons satisfied with what others would regard as a very mediocre kind of success with antiseptic treatment.

The circumstances to which I referred at the beginning of this address naturally made me turn my attention to corrosive sublimate; and I was desirous, if possible, to use it in a more concentrated form, so that it might be employed in a less bulky fashion; accordingly I prepared a gauze containing, instead of ½ per cent., 1 per cent. of the sublimate.

The first case in which I used it was that of an elderly lady, from whom I removed the mamma and cleared out the axillary glands. I put immediately over the wound a piece of prepared oiled silk, which I dipped in a 1 to 500 solution of corrosive sublimate; then, over this, sublimate gauze, and outside all an abundant eucalyptus dressing. On the following day, when we changed the dressing, I found that, under the oiled silk, exactly corresponding to its extent, the skin was highly irritated, and was covered with small vesicles. I also found that the inner side of the arm, where there was no wound, was in the same state of intense irrita-

Digitized by Google

tion. I covered the irritated parts of the inner side of the arm with eucalyptus gauze, dipped in a weak solution of carbolic acid, and I applied to the wound the 1 per cent. sublimate gauze without any intervening protective oiled silk. On the following day I found that the little vesicular pustules, which had formed on the first day under the protective, had healed, and that the inner side of the arm also had recovered from its irritation. How were these facts to be explained? I believe the explanation to be this. The 1 to 500 watery solution of corrosive sublimate, prevented by the oiled silk from escaping, had acted as a powerful irritant upon the skin; but when the 1 per cent. gauze was applied directly to the wound, the oozing of albuminous discharge from the pustules and from the edges of the wound mitigated the action of the corrosive sublimate, and so prevented further irritation there. Again, in the case of the arm, what had occurred was, free perspiration had taken place, and the perspiration forming, with the corrosive sublimate in the gauze, a watery solution, had produced irritation where the perspiration was, on the same principle as the watery solution had caused irritation under the protective.

I continued to use a corrosive sublimate dressing in this case. It so happened that there was a very free hæmorrhage after the operation. I never before saw small vessels so atheromatous. We had to tie multitudes of little rigid arteries, and, in spite of this, a considerable effusion of blood took place, and bagged under the skin. She left town with the outer angle of the wound still unhealed, and having the remains of the blood-clot exposed in it; the dressing employed being a piece of absorbent cotton-wool charged with about 5 per cent. of sublimate, secured in its place with collodion, and she came every few days to London to have the dressing changed. On these occasions I found that although the serous discharge had soaked the wool more or less, there was no irritation caused by it; and the blood-clot, in course of time, presented an appearance which I never happen to have seen before. From the epidermic edges of the little wound the epidermis crept over the surface of the blood-clot like the white claws of an animal extending over the dark coagulum. We are familiar with the organisation of the coagulum in exposed wounds, and we are also familiar with the fact that in the course of time the superficial clot may be removed, and a scar found under it, without any suppuration having taken place, or any granulation, strictly speaking; but I never happened to have seen before this formation of epidermis extending over the surface of an exposed coagulum; and the explanation I believe to be that, while a sublimate wool rendered the wound for surgical purposes perfectly aseptic, the albuminous discharge from the wound prevented the sublimate from coming into operation as an irritant, and so we had, in a peculiarly perfect manner, complied with the essential conditions for the treatment of superficial sores—namely, the exclusion on the one hand of septic agency, and on the other of the irritating property of our dressing. I may add that the wound healed without a particle of pus having been formed from first to last.

While this case showed that in the sublimate we had an agent that might give very beautiful results, it also indicated that we were dealing with an edged tool, which, while it might do admirable work, was very apt also to cut our fingers; and the question suggested itself, Was it, after all, possible to use corrosive sublimate in such a way as to get the advantages without the disadvantages? The question, for instance, suggested itself, Suppose the discharge had been more considerable in this case, so as to soak thoroughly through and through the dressings, what might then have been the result? What is the action of the albumen of serum or blood upon corrosive sublimate? How do they act upon each other? It is, I believe, a very general view in the profession, not to say among professed chemists, that albumen forms, with corrosive sublimate, an insoluble, or very sparingly soluble, albuminate; and that this albuminate is inert; whence the efficacy of white of egg as an antidote in corrosive sublimate poisoning. In the fourth edition of Miller's "Chemistry" it is distinctly stated that an albuminate of mercury is formed as a precipitate when a solution of albumen is treated with corrosive sublimate. In the third appendix to Watts's "Dictionary of Chemistry" the albuminates are still spoken of, and, in the intermediate appendices, there is nothing said to interfere with the view expressed in the original work—viz., "Mercuric albuminate is a white substance obtained by precipitating corrosive sublimate with albuminate of sodium (white of egg)." If it were really true that the albumen, acting in a certain proportion on the corrosive sublimate, would form with it an absolutely inactive compound, this would be a very serious consideration for the use of corrosive sublimate in surgical practice. The albuminous (proteid) constituents of the blood are enormously abundant; while the quantity of corrosive sublimate we can use in our dressings cannot be very great. According to the most recent views regarding albumen, its chemical equivalent is about six times that of corrosive sublimate; but the quantity of albuminous material in the serum of the blood is very much more than this in proportion to any amount of sublimate that we could have in our dressings. My first experiment upon this matter was as follows. I made a solution of albumen from white of egg, and then introduced it into some sublimate-wool, the quantity of albumen used being double that which would be requisite to neutralise the corrosive sublimate, according to the view to which I have referred. After leaving the albuminous fluid in the wool for a certain time, I squeezed the wool, and obtained a clear fluid, and I was surprised to find that this clear fluid tasted strongly of corrosive sublimate—an albuminous fluid containing twice the quantity of albumen that was essential, according to the views to which I have referred, for neutralising the corrosive sublimate—had picked up from the wool corrosive sublimate enough to give the fluid that came out a strong taste of that substance. I mixed this liquid with an equal part of milk obtained from a dairy, and the milk remained perfectly free from souring, showing that the albuminous fluid which had come through the wool had antiseptic qualities, as well as the taste of corrosive sublimate.

I afterwards made other experiments with blood itself, and that to which I will now refer was with the serum of horse's blood. My first attempt to obtain serum from horse's blood failed. I wished to get the blood in an aseptic state, so far as one conveniently could without going too much into detail; and I used a glass jar which I had had by me for a long time past, and which had been used for experiments with regard to catgut, and had certain impurities adhering to it which could not be cleaned off. I purified this with 1 to 500 solution of corrosive sublimate, and then introduced into a horse's jugular vein a glass tube purified in the same way, and through this tube drew blood into the jar and allowed it to coagulate, intending to use the serum which should ooze out of the clot as it contracted. I was baffled, however, by finding myself again in presence of a fact which I described some years ago, where antiseptic precautions had been used in obtaining blood; the clot never contracted.

When I first witnessed this fact, having found the novel procedure of antiseptic precautions in taking blood followed by the novel phenomenon of failure of the clot to contract, I was disposed to attribute the one to the other, and to imagine that the destruction of the septic organisms was in some way or other the cause of the absence of the shrinking. Then it was suggested to me that Liebig had shown, in his "Letters on Chemistry," that if glasses are heated they lose for a time their usual property of causing certain phenomena of crystallisation; and, as my glasses had been always purified by heat, there might be some peculiar physical property in the glass to account for the circumstance. But here we find the same phenomenon cropping up, although the glass had not been purified by heat, and although it had not even a clean smooth surface.

It may be interesting to you to observe that, though the antiseptic precautions used were but of a rough kind, still no genuine putrefaction has occurred, in spite of the hot weather, in this blood taken on September 9th; but the remarkable fact to which I wish to direct your attention is that, while the buffy coat peculiar to horse's blood can still be recognised, it has entirely failed to contract, and is to be seen adhering to the surface of the vessel. I must confess it seems to me barely conceivable that the development of organisms can be the cause of the contraction of the clot under ordinary circumstances, considering how soon that contraction begins to come into play. Yet to what else are we to attribute it? It is to me, I confess, a perfect mystery. At the same time, to us surgeons it must be admitted to be highly interesting, because in antiseptic surgery, at all events, this is the very condition of things in which we find the clot. We do not find a clot shrink away, or tend to do so, from the sides of the wound, but it retains its original bulk until it is gradually diminished by absorption and organisation; and if a clot forms in the vicinity of a ligature upon a large artery, it seems very important that it should not shrink away from the sides of the vessel; but

Digitized by Google

remain there in its original dimensions to serve its purpose of a plug.

On the same occasion on which I obtained this blood, I received a portion into another vessel, and stirred it during coagulation so as to remove the fibrin. This whipped blood answered my purpose perfectly, because by virtue of the remarkable tendency that the red corpuscles of the horse's blood have to aggregate into dense masses, and so fall rapidly in the course of a short time, the mixture of serum and red corpuscles was found in three hours to consist of about one-half corpuscles and one-half serum, and therefore I could use the serum for the purpose of my experiment.

The experiment was performed in the following manner. A glass tube such as this (three-quarters of an inch in calibre and three inches in length), open at each end, was packed with a certain weight of antiseptic dressing to be tested, say sublimate wool, occupying about two inches of the tube; then a weighed quantity of serum, just enough to to soak the wool, was poured in at one end of the tube held vertically; it was then left for about half an hour in a warm box, at the temperature of the body, after being put into a stoppered bottle to prevent evaporation; then the serum and the sublimate in the dressing having been allowed to act upon each other for about half an hour, a little more serum was poured in, the tube being in the same position as before. The result was that a certain quantity flowed out below, and was received into a test-tube. The lower part of the wool and the serum in the test-tube were next inoculated with putrid blood, diluted with ten parts of water, to prevent the smell being so great as to make you think that putrefaction existed when none had occurred, a tenth of a minim being applied by means of a suitable apparatus. Lastly, the wool-tube in its stoppered bottle, and the test-tube with a cap of thin mackintosh tied over its mouth, were replaced in the warm box. The object of this was to ascertain whether the dressing, after having been thoroughly soaked through and through with serum, would resist a potent septic inoculation; and also whether the fluid that had come through the dressing was itself an antiseptic fluid. If such should prove to be the case, we should have all the requisites we could desire for an antiseptic dressing. It was a very severe test, for it is comparatively rarely that we have such intensely putrefying substances applied to the surface of our surgical dressings, and it is also comparatively rarely that the dressings are soaked so very thoroughly with blood or serum.

I used three kinds of sublimate-wool, one containing 1 per cent.—twice as much as there is in the wood-wool—one 5 per cent., and the other 10 per cent. I have mentioned that it was on September 9th that this was done, and all these three wools remain perfectly pure, so far as the sense of smell can detect, to the present time. The bottles are before you, and even in that containing the 1 per cent. wool you will find nothing but a smell something between mortar and the inner bark of some trees, which is the immediate effect of the action of corrosive sublimate upon the serum. The serum that had come through the dressing equally resisted the inoculation. By means of a process of testing with which I will not now trouble the Society, I could ascertain pretty exactly the proportion of corrosive sublimate present in these liquids that had thus come through. The corrosive sublimate made the liquids turbid in the case of the wool with stronger proportions; but in the case of the 1 per cent. it had not rendered the serum turbid, and therefore I was able, without the use of the microscope, to judge by the existing transparency, and also by the presence or absence of scum on the surface, whether any organisms did or did not develop; and none whatever occurred. As regards the strongest wool, the liquid which came through contained about one part of corrosive sublimate to 160 parts of the fluid. I tasted this, and found it had the peculiar metallic nauseous taste of corrosive sublimate. I also mixed some of it with five parts of milk got from a dairy, and, therefore, as we know, teeming with bacteria of various kinds. Here is the milk, still fluid after the lapse of nearly six weeks, although when it was mixed with the serum it was already advancing towards septic changes. The first of those changes—namely, lactic fermentation—has been prevented, otherwise the milk would not have been fluid, as you see it to be. There is not the slightest smell either of the lactic or butyric fermentation, but only that which Pasteur pointed out to occur as the result of oxidation of the fatty matter of milk—a little odour of suet. That is exactly the smell that you have in boiled milk kept for a few weeks in an aseptic state.

Thus, Mr. President, we had evidence that corrosive sublimate forms, with the serum of the blood, a material whether we call it a chemical compound or not, which retains the properties of the corrosive sublimate, both as to taste and as to antiseptic virtue. Now, it seems to me highly unlikely that both the characteristic taste of corrosive sublimate and the antiseptic virtue would be retained if the corrosive sublimate were decomposed in any way; and, therefore, I venture to think, speaking with all deference to chemists, that we have not here a chemical combination in the ordinary sense, but an association of particles, such as occurs in solution; not an albuminate of mercury, but an albuminate of sublimate, if I may use such an expression: a loose association of particles of chloride of mercury with albumen. If such be the case, I need hardly point out how important this may be with reference to the surgical uses of corrosive sublimate. The discharges, in passing through a sublimate dressing, may acquire from that dressing chloride of mercury, still in solution, though associated with albumen, and still retaining antiseptic properties.

I may conclude this matter of the relations of the blood-serum to corrosive sublimate by showing some illustrative specimens. I found that if serum is mixed in small proportion with corrosive sublimate in a mortar, the result is the production of a thick opaque, slimy material; but if you add a little more, and still a little more, you get this material redissolved in the serum, until, if you use as much as 150 parts of serum to 1 of sublimate, you get a clear solution. This test-tube contains serum from the blood of a horse mixed with one-two-hundredth part of corrosive sublimate. You will see that there is no precipitate here at all. This other test-tube contains the same amount of corrosive sublimate (1 to 200); but the liquid mixed with it, instead of being serum simply, is serum with an equal part of distilled water; and here we have what the chemists describe as a precipitation of the albumen, the upper part of the liquid being clear. Now, this upper part of the liquid contains exceedingly little corrosive sublimate; it has almost all gone down with the albumen; but, if we take some of this precipitate itself and mix it with more serum, it will be redissolved by that serum. This afternoon I mixed some of this precipitate with some serum already containing one-four-hundredth part of sublimate, and the result has been the clear solution that you see here. This albuminate, if we are to call it so, is therefore highly soluble in blood-serum, and that is one important point to which I wish to direct attention.

While the sublimate is thus, so to speak, intact when associated with albumen, it is rendered very much milder in its action. I took some of the serum which had come through the 10 per cent. wool, containing one part of corrosive sublimate to 160 parts liquid, soaked a piece of lint with it and applied it to my arm, put over this a piece of thin mackintosh cloth to prevent evaporation, and secured this with rubber adhesive plaster. I retained this in position for twenty-four hours, and on its removal found an absolute absence of any irritation, although my own skin is pretty sensitive. We have seen how, in twenty-four hours, 1 part of sublimate to 500 of water already produced pustules; yet here 1 part to 160 of serum produced no irritation whatever. The association, then, of the albumen with the corrosive sublimate greatly mitigates its action, and makes it much less irritating. Thus we are able to understand how the discharges coming from a wound soaking a sublimate dressing may not cause irritation, although the dressing may contain a large proportion of corrosive sublimate. Such being the case, I hoped that we might be able to use corrosive sublimate in pretty strong proportions in a gauze for the dressing of wounds; and therefore, not very long ago, in a case of psoas abscess, I applied gauze containing 5 per cent. of corrosive sublimate with a little gum Arabic to prevent the crystals flying off. On changing the dressing the following day, I saw in the vicinity of the wound all perfectly satisfactory; but the discharge having gone principally backwards, I found that the further I looked towards the sacrum, the more and more evidence of irritation did I find, until over the sacrum itself, beyond the edge of the dressing, there was absolutely a large vesicle. How was that to be explained? The expanation I believe to be simply this. If an albuminous discharge travels through a dressing containing corrosive sublimate only, it, in the first instance, forms, with the corrosive sublimate, a non-irritating albuminate, so to speak, but leaves

Digitized by Google

more or less of its albumen behind in the form of a precipitate. As it goes further, and meets with more corrosive sublimate, it leaves more albumen behind, and so, as it advances, becomes more and more nearly a watery solution of corrosive sublimate, producing the highly irritating effects with which we are familiar. This result I confess made me at first despair of using corrosive sublimate in anything like a concentrated form as a surgical dressing. But it afterwards occurred to me, might it not be possible, as corrosive sublimate associated with albumen is so little irritating, to associate albumen with the corrosive sublimate in the dressing? Where should you get your albumen from? Well, we may get it from horse's blood. There are in every town horse-slaughters. If you stir horse's blood while it is coagulating, you may get from one animal some gallons in the form of serum. There is the albumen for you, if it only can be made useful. There is a horse-slaughterer in the north of London who will let us have this serum absolutely for nothing; it is simply a useless material to him. This being so, I ascertained in what proportions the serum and the sublimate might be mixed, so as to give a workable article; and I find that you may employ them in almost any proportions. If you use a very small amount of serum, you get, indeed, a thick opaque substance; but this can be perfectly well blended with gauze or other materials. Here is a gauze which has been charged with serum containing 1 part of corrosive sublimate to 75. Two and a half parts of the liquid are required for one part of the gauze; and you will see that this is not at all an unpleasantly constituted substance, physically. It is destitute of odour; you will scarcely perceive it to the taste; and you would hardly believe that it contained nearly three parts per cent. of corrosive sublimate.

The corrosive sublimate is so intimately blended with the serum that when it dries (as seen on this plate of glass) no separation of crystals takes place. Whether we use 1 to 100, 1 to 70, 1 to 50, or even 1 to 30 parts of blood-serum, they are perfectly amalgamated, and therefore, from a gauze like that, no corrosive sublimate can fly off. It can be manipulated as you please. And as applied dry to the skin, it is absolutely unirritating. If, however, such a gauze is torn, it gives off a dust which irritates the nostrils. It is therefore better to cut it with scissors. Then, in the next place, it is unirritating as acted on by the perspiration. If water is made to act on sublimated serum dried, it does not redissolve it, as serum does, but it renders the mass opaque, the water being only partly absorbed into it; and the water which remains unabsorbed contains exceedingly little of the corrosive sublimate, which is almost all retained by the albumen. Hence, when perspiration soaks into such a dressing, though it moistens it, it does not produce irritation. I made some gauze with serum so strong with corrosive sublimate as to have 1 part to 30, which implies more than 6 per cent. of corrosive sublimate in the gauze. I moistened a piece of this with distilled water, and fixed it on my arm for six hours in the manner before described; and, when I removed it, I found the skin free from irritation. Thus, you will observe that, by associating albumen with the corrosive sublimate, we seem to be able to get rid of its irritating properties.

But the important question arises, Does corrosive sublimate, when thus associated with albumen, retain sufficient antiseptic virtue for surgical purposes? The method of experimenting which I have described is adapted for testing the efficacy of any antiseptic dressing, and I have used it for various others besides sublimated ones. I have employed it with serum for salicylic cotton-wool, for iodoform cotton-wool, for eucalyptus gauze, and for carbolic gauze. I have mentioned that the test is an exceedingly severe one, and I find that after the lapse of a few weeks, salicylic wool soaked with serum and inoculated as above described stinks, and the same is the case with iodoform wool; the eucalyptus gauze, however, if freshly prepared remains pure, as also does carbolic gauze. We have seen that the 1 per cent. sublimate-wool resisted, still more the 5 per cent. and the 10 per cent. In accordance therefore with our previous experiments with iodoform and salicylic acid, they did not stand the test as well as carbolic acid, or eucalyptus, or the corrosive sublimate. But we get a different result if, instead of using serum of blood, we use serum mixed with blood-corpuscles, such as we readily get from the cow, in which the corpuscles do not aggregate so closely as in the horse, but remain suspended in the serum. I need not, of course, tell any members of this Society that the corpuscles are enormously richer in proteid substances than the serum is, so that serum and corpuscles contain about two and a half times as much of proteid material as the serum does; and as albuminous materials mitigate the action of the corrosive sublimate, they cannot fail to interfere more or less, also, with its antiseptic action; and when we use serum and corpuscles, instead of serum only, we find that the sublimated wood-wool (which I should have said did very well with the serum so far as the sense of smell indicates) fails completely. The 1 per cent. sublimate-wool failed also; the 10 per cent., however, stood the test perfectly, even with blood in substance. Now, as to our gauze made with albumen associated with the sublimate, the sero-sublimate gauze. Such a gauze prepared with 1 part of sublimate to 100 of serum stood the test absolutely when tried with serum. It therefore proved itself superior to salicylic and to iodoform wool. But with the blood in substance, how does it behave? The tube in this bottle contains a portion of the gauze treated with the cow's blood, serum and corpuscles, and inoculated nearly a month ago in the same potent manner to which I have referred, and you will observe that it has no putrid odour. Really, then, this sero-sublimate gauze seems to stand the test completely. I may say that, when tried with corpuscles and serum, our best eucalyptus gauze failed utterly, so that everything failed that I have tried except the stronger sublimate preparations and the carbolic acid gauze.

Then the question comes, How far may we go in the strength of our sublimate combined with the albumen without causing irritation? During the last three weeks, my cases at the hospital have been dressed with this material. We have used the kind of gauze which you have in these bottles, made with 1 of sublimate to 100 of serum, and also one made with 1 of sublimate to 50 of serum. We find that the 1 to 50, in the majority of cases, has caused no irritation whatsoever, but in a very few it has caused some irritation, which, however, has disappeared, and the sores caused by the 1 to 50 have healed when the 1 to 100 has been substituted for it. Therefore it looks as if we were very near our limits, as if that prepared with 1 of sublimate to 100 of serum was trustworthy and unirritating, even to all skins, and that prepared with 1 to 50 was unirritating to most skins. Now, there is this to be observed for our comfort, that the discharge both from wounds and from abscesses antiseptically treated is a serous discharge, not a bloody one, except in the case of wounds during the first twenty-four hours; and even in the first twenty-four hours, except in cases in which the dressing has to be taken down for reactionary hæmorrhage, the blood is always more or less diluted with serum. If, therefore, we have a dressing which has stood our severe test with serum mixed with the full amount of corpuscles, we are surely not wrong in regarding it as trustworthy.

Last Friday I amputated at the hip-joint in a boy twelve years of age, on account of a sarcoma of the lower half of the femur. The wound was exceedingly vascular, and there was a great deal of bloody oozing in the first twenty-four hours, but very little escaped externally, because this gauze absorbs very much better than our carbolic acid or eucalyptus gauzes do, containing as they do resin and paraffin; and I would strongly recommend that during the first twenty-four hours this gauze should be used in abundance, in at least sixteen layers. It is now three days since the operation was performed, and, from the perfectly normal temperature and returning appetite and strength, I think we may be satisfied that the boy is already out of risk of septic complications. And this, you will observe, is a very testing case.

I may mention one other case, that of a boy six years old, from whom, nearly three weeks ago, I removed a portion of a rib for the purpose of allowing free drainage to empyema. We let out thirty ounces of thick odourless pus, and a great quantity came out afterwards. He has been dressed with sero-sublimate gauze; and he is one of the instances in which gauze prepared with the 1 to 50 serum caused irritation which disappeared under the 1 to 100.

In him we have witnessed the beautiful course which, I believe, we can only see under antiseptic treatment efficiently managed, of no more pus formed after the first pus has been evacuated, nothing but a serous oozing rapidly diminishing; and it was astonishing to see, on coming back after a fortnight's absence, how plump the emaciated little fellow had become. And the serous discharge is now so slight that I

Digitized by Google

believe it would be already safe to remove the drainage-tube. This case, I think, proves that our dressing is aseptic, that the germicidal properties of the corrosive sublimate have come into play in the preparation of the dressing, so that any injurious organisms which existed in the blood or in the gauze before they were brought into preparation, have been destroyed; because, if there had been merely the inhibitory influence of the sublimate upon the organisms, the serum pouring out from the pleura, and washing away all the antiseptic in the vicinity of the wound, but leaving the organisms lodging among the fibres, then we should have had putrefaction, or other disturbing causes, showing themselves. No such thing having occurred, this case seems of itself sufficient evidence that our dressing is really a safe one, in so far that it contains no living organisms of importance to start with.

I have here a sample of a very cheap fibre, sent me from the south of France, prepared with this sublimated serum, and then teased out, showing that we may use this material for charging various fabrics. This is highly absorbent; and I may remark that, if we have a very highly absorbent dressing, we may, and must, use a larger proportion of the sublimate. A gauze will absorb only about three times its weight of liquid; cotton-wool will absorb ten times its weight; and therefore you observe, when the one dressing is saturated it has three times as much of the liquid in it, and thus has the sublimate three times as much diluted. Being so much diluted it will be in proportion less irritating, but the stronger proportion is required to make it safe unless you use it in a very large mass. I believe the French charpie made of old rags, or even old rags themselves, might be quite well prepared with sublimated serum. I have here some rags which have been so treated, and which are quite absorbent, and therefore the dressing promises to be a very cheap one. If the serum is treated with a certain proportion of sublimate, not sufficient to make it solid, it may be kept for any length of time. For aught I know, this sublimated serum may come to be an article of commerce, which may be used in hospitals, or even in private practice. I also think it possible that a material of this kind, dried and reduced to powder, may come to be used for the purpose of mixing with vaseline for an antiseptic ointment, or even for dusting in, under certain circumstances, among our dressings.

I regret that time has not allowed me to bring this matter more completely to an issue as regards its practical application. At the same time, though the subject is, to a certain extent, immature, I ventured to hope that the interest of some of the points to which I have referred might justify me in bringing it before your notice.

ON "LAWN-TENNIS LEG."

By WHARTON P. HOOD, M.D.

THE great popularity of lawn-tennis has given the above name to an accident which has long been known to surgeons, but which the particular kind of effort required by the game has of late years rendered much more frequent than heretofore. It consists of the rupture of some portion of the muscular or tendinous structure of the calf.

Several years ago, when writing for THE LANCET some papers on so-called "bone-setting"—papers which were afterwards republished in a volume,—my attention had already been called to the very protracted disability by which this injury was sometimes followed when treated in the ordinary way. The Hon. Spencer Ponsonby Fane kindly furnished me, for the work in question, with the particulars of an accident of the kind which happened to himself in November, 1864, and by which he was crippled until June, 1866, a period of nineteen months. Mr. Fane then came under the care of the late Mr. Hutton, who told him that his "ankle was out," and who performed an operation for the purpose of "putting it in." This operation immediately cured his lameness; but when the details first came to my knowledge, I was unable to explain what had happened. By the light of subsequent experience I was led to believe that the elevation of the foot and extension of the limb, which followed the injury, had caused the weight of the body to throw upon the injured tendon, thus producing irritation which led to the formation of adhesions, and that these adhesions were broken through when the imaginary dislocation was reduced. However this may be, it is certain that the patient was cured. I need hardly say that the duration of disability in Mr. Fane's case was exceptional; but every surgeon knows that weeks, or even months, may elapse before recovery from a similar injury is complete. I was led by this consideration to adopt a method of treatment by which I hoped to obtain better results, and it has been so successful in my hands, that after a large experience of its efficacy I am desirous to make it known to the profession. It is based upon two essential points—namely, adequate support for the structures of the calf, coupled with immediate and uninterrupted use of the limb.

As soon as possible after the occurrence of the rupture, the patient should be placed upon a sofa, with his injured leg raised above the level of his head; and should be kept in this position for five minutes. This is an important preliminary, because the position alone will be sufficient to empty the limb of superfluous blood, and thus to reduce the swelling which is commonly present. A calf which is much enlarged, and very hard, will frequently return to its natural dimensions within the time specified; and the patient will at once obtain relief from the oftentimes distressing feeling of tension. Moreover, if the elevation of the limb be neglected, the plaster next to be described will soon be loosened by the subsidence of swelling, and will require to be replaced within a few hours. After a sufficient period of elevation, and while the leg is still raised, strips of adhesive plaster, each an inch and a half in width, and of length adapted to the size of the limb, should be applied from two inches above the ankle-joint to above the thickest part of the calf, somewhat as strapping is applied in the treatment of chronic ulcers of the leg. When the plaster is well adjusted, it disperses the effusion of blood and lymph and restores the natural flow of the circulation; while at the same time it holds all the muscular and tendinous structures firmly together, and practically converts the sound portions into a splint for those which are torn. As soon as the plaster is applied, the patient should be directed to walk about the room and to place the heel firmly, or at least fully, on the ground at each step. For the first dozen steps he will probably hesitate, and will maintain more or less of the limp with which he entered; but after a short time, finding that his pain is diminished, or possibly removed, he will gain confidence, and will walk with a pride in his own performance which is very interesting to witness. Until this point is reached, he should not be suffered to depart; for, if he does not walk properly before he leaves the surgeon, he will hesitate still more when alone, and will be likely to return to the ungainly progression which he exhibited at the commencement of the interview. Success in walking, in the first instance, will depend largely upon the temperament of the injured person. A resolute man, who believes in his doctor, will walk at once, while a more timid patient will require coaxing and urging. The chief trouble will be with the sceptical man, who has his own "views" about the injury, and who will express them in such questions as "Well, but do you not think there is a risk of inflaming my leg?" "Shall I not make the internal wound larger?" and so forth. With reasonable care neither to jerk the leg nor to twist the ankle on uneven ground the patient, as soon as the plaster is applied, may walk about as usual. By the third day the plaster will be somewhat loose, and the patient will say that he is not quite so comfortable as before, and is less inclined to trust his leg. The strapping should be reapplied, and he will at once feel more secure and better able to walk. Four days may elapse before the next strapping, which may be left untouched for a week, but the application should be continued at intervals until the patient is quite convinced of his ability to do without it. On the first occasion very little pressure is desirable, and more laying on of the plaster will be sufficient. Subsequent strappings should be tighter, but never so tight as to produce a sense of unpleasant constriction, a rule which must be especially borne in mind in applying the first and last strapping. The amount of walking should be increased daily, and after the third day the patient should go up and down stairs only in the usual manner. Until then his ascents and descents may be infantile.

The above described method of treatment is always successful with, and as a rule is more necessary for, old or elderly than the young. With the latter [illegible]

Digitized by Google

reasons, the accident is of rare occurrence. When it does occur the sufferer is eager to get back to his games. He makes light of his pain, has no fear of inflammation, covertly uses his limb, even in defiance of medical orders; and, as his cure is rapid under any treatment, he is usually believed by his surgeon to have sustained only a slight tear. The elderly man, on the other hand, is probably inclined to think that he has been foolish at his time of life, and with his muscles out of training, to engage in a game requiring active exertion. He regards the accident as a lesson in prudence, is fully alive to the value of a sound limb, and sets himself to nurse the injury, with the idea of obviating a wholly imaginary danger of inflammation, or of retarded union of the ruptured parts. By strapping and compulsory exercise he is, in fact, protected against himself. In addition to the rapid cure which it effects, to the prevention of loss of health from want of exercise, and of loss of other kinds from absence from business or occupation, my method has the further advantage of diminishing the liability to recurrence of the accident. The prolonged rest and raised heel, which have generally been enforced in such cases, have a tendency to produce contraction, or a cramped or shortened condition, of the whole of the muscles of the calf, and thus to permit the torn fibres, when united, to be shorter than those around them. At the termination of a case treated in this manner, when absence of pain indicates cure, the patient is able to walk with comfort on even ground, but has acquired the trick of doing so with an almost imperceptible degree of flexion of the leg. When called upon for any extra exertion he is apt to be reminded of his old trouble by a sensation of tearing, or an actual tear, at the seat of the former rupture. This sensation may arise from simple stretching of the cramped muscles, and is then only transitory; but sometimes, from perfect extension being suddenly attained, the contracted portions are compelled to bear the entire strain of the movement, and actual rupture may be the result. In either case the pain is looked upon as evidence of a recurrence of the accident, and a further period of rest is enjoined. All this may be avoided by insisting from the outset that the heel shall be placed fairly upon the ground whenever exercise is taken.

The foregoing observations are founded upon the experience of the last fourteen years, and upon a large number of cases; but this year, among many others, I had what I may fairly call a typical example of the injury in the person of Dr. W. G. Grace, the justly celebrated cricketer. He came to me on the 13th of June, having had the characteristic feeling of having been smartly struck on the calf on the previous evening while playing at Lord's. He was compelled to discontinue his innings, having made sixty runs. He limped into my room, expressing the opinion that "he was done for for the season." On passing a finger down his calf a distinct sulcus could be felt, and his impression was that "he dare not put his heel to the ground to save his life." I strapped up the leg, and he walked away, putting his heel fairly to the ground. The next morning he continued his innings, having some one to run for him, and he added twenty-four runs to his overnight score. He did not cease playing cricket, and an extract from a letter from him, dated July 13th, will finish what I have to say about his case. "You will be glad to hear that my leg has been improving ever since, and is, in fact, well. The accident happened at Lord's on June 12th, and I consulted you the following morning, and found immediate relief from your treatment. You strapped it up from time to time, the last time on June 26th, on which day I played at the Oval against the Australians, and ran for myself 107 runs. My leg was no worse after this, and has been improving every day. I felt myself quite well at Manchester on July 10th, so my leg was cured under the month. I never rested my leg a single day."

The more speedily the strapping is applied after the injury the better will be the result, a point which is well illustrated by the following case. I was playing lawn tennis with a friend whose weight is fifteen stone. I served a ball to him, and he ran forward to take it, but missed it; and then stood still on one leg, like a large bird roosting, gazing round the court. Seeing him remain in this position, I asked what he was looking for. His reply told the whole story. "Some one threw a stone or a ball at me, and hit me on the calf; and, by Jove, it hurts." He went home with me, I strapped up his leg, and in three weeks I had the pleasure of playing three "sets" with him. He had all his customary activity, and, like Dr. Grace, he had not laid up for a single day.

Seymour-street, W.

ON THE PATHOLOGICAL IMPORTANCE OF FLEXIONS OF THE UTERUS.

BY G. ERNEST HERMAN, M.B. LOND.,
OBSTETRIC PHYSICIAN TO THE LONDON HOSPITAL, LECTURER ON MIDWIFERY, ETC.

(*Continued from p. 675*)

2. *Post-mortem Evidence.*—There is proof that flexion of the uterus may prevent the exit of fluid—(*a*) if the uterus be fixed in the bent position by adhesions, and (*b*) if the wall of the uterus be thinned by senile atrophy; conditions which impair the contractile power of the uterus. I have in the papers to which Dr. Hewitt refers quoted the cases which support these two propositions. Dr. Hewitt complains that I have slurred them over; but I have admitted there, and would here again express myself convinced, that there is sufficient evidence in favour of these two propositions. There is another case on record which bears on the question, and which I infer Dr. Hewitt thinks important, while I do not. It is very briefly reported by Scanzoni; it is mentioned only, not described. Scanzoni expresses strongly his opinion that flexions *per se* cause no trouble. If this briefly mentioned case were really conclusive or important, surely it would have influenced the opinion of the distinguished writer who saw and examined it. In the absence of a description so detailed as to enable the reader to draw inferences for himself, I think we are not justified in assuming that the case negatived the view taken by the reporter; and we must assume this, if the case is to support Dr. Hewitt's views. Beyond these cases, there is no post-mortem evidence that so far as I can discover has ever been adduced to show the correctness of the diagrams which appear in many books (Dr. Hewitt's among the number), representing the uterine canal sharply bent, narrowed at the point of flexion, and the uterine cavity dilated above the constriction. On the contrary, every specimen that is to be found in museums (except those in which the uterus is fixed by adhesions) exhibits the canal bent in a gentle regular curve, without any constriction, and with the walls of the uterine cavity quite as close together as they are in uteri which are straight. The importance of post-mortem evidence in the controversy relating to the effects of uterine flexion depends upon the view which it is sought to substantiate. The absence of post-mortem evidence does not prove that flexion never causes dysmenorrhœa; and therefore, if it be only maintained that flexion sometimes and rarely produces dysmenorrhœa, this view is not contradicted. But if, as Dr. Hewitt believes, flexion is the cause of the vast majority of functional uterine disturbances; if the diagrams in his book represent conditions present in the majority of women who consult medical men for dysmenorrhœa; then I think it astonishing that morbid anatomists should never find anything to show the past or present existence of such common changes; and I think the absence of specimens illustrating these changes is a strong presumption that the changes are at least not so common as they are supposed to be, if they even exist at all. There is a condition demonstrable anatomically upon which I have laid stress,[1] but my references to which Dr. Hewitt dismisses as mere trifling—viz., the effect of unusually well-developed utero-sacral ligaments when the body of the uterus has been forced down between them. I will not go over again the considerations which lead me to attach importance to the effects of these structures. I will only say that the possibility of the effects described can be observed by anyone who will examine fifty or a hundred female dead bodies, and that the actual production of them has been proved by a well-observed case; and so much as this cannot be said for the morbid changes which are assumed to result from mere flexion of the uterus. Dr. Hewitt regards the condition of which I speak as unimportant, because he has not always been able to feel these bands. I submit that the examination of the relations of the uterus in the dead body is less liable to error than vaginal and rectal examination during life.

3. *The Interpretation of Signs and Symptoms.*—It is here that I find myself most at variance with Dr. Hewitt. Some of the common clinical observations which to him seem important appear to me scarcely to need considerations

[1] Obstetrical Transactions, vol. xxiv.

Digitized by Google

while other facts, which to my mind tell powerfully against the flexion theory, he makes no attempt to explain; and at to a third class of observations, his experience is so different from mine, and from that of others who have studied the subject, that I cannot reconcile them, but must leave it to those interested in the subject to observe for themselves and decide which is right. Dr. Hewitt puts forward as clinical evidence of the morbid effects of flexion the escape of menstrual and leucorrhœal discharge in gushes, the passage of clots at the menstrual period, and enlargement of the body of the uterus at the menstrual period. To give these clinical phenomena any value as evidence bearing on the question, it ought to be shown that they occur only or with much greater frequency in those women in whom flexion of the uterus is present. Dr. Hewitt does not seem to have instituted any inquiry into the frequency with which clots are passed and fluid said to escape in gushes in women with bent and straight uteri respectively. I have not made any such inquiry myself, not thinking it worth the trouble; but if such evidence is thought worth consideration, it appears to me that this is the first point to be settled. Were such an inquiry made, I believe it would be found that the clots and gushes would be described pretty nearly as often, in proportion to their number, by women with straight uteri as by those with flexion. I do not think it of moment, because in the great majority of cases in which clots are passed, it is impossible to say whether the blood coagulated in the uterus or in the vagina. It is my rule, when patients say that they pass clots, to ask them to bring them for me to see; and I generally find them small and recent, and telling nothing by their shape of the place in which they were formed. As to the gushes, the correctness of the fact rests entirely upon the patient's statement, and patients—females especially—can so seldom describe with scientific accuracy, that to build a theory on such descriptions seems to me to be building on sand. Of course we must take the patients' statements when it is only through them that we can get the information we want, and I quite agree with Dr. Hewitt that their complaints ought not to be treated as fanciful; but subjective symptoms stated by patients ought not to be seriously put side by side with things seen by trained observers. Granted that discharge does escape in gushes, what evidence is there that the accumulation was in the uterus, and not in the vagina? It is common enough for secretions, and occasionally air, to be retained in the vagina in much greater quantity than the unimpregnated uterus will hold. In short, these phenomena do not influence my opinion, for the reasons—(1) That the fact of the occurrence of the gushes rests only on the sensations of patients; (2) if gushes and clots do escape there is no evidence that the expelled products were retained in utero; (3) no evidence has been adduced to show that they are at all peculiar to women whose uteri are bent.

There is an observation of Schultze's bearing on the supposed accumulation of fluid in the uterus behind a bend in it, which I quoted in one of my papers, and which I must allude to here because Dr. Hewitt, doubtless through my fault, misrepresents its meaning. I did not cite the mere fact that Schultze had passed the sound into an anteflexed uterus during the height of the menstrual pain as evidence that the canal was not obstructed. The point of the observation, which Dr. Hewitt does not mention, is this: that when the instrument was so passed, at the height of the pain, no escape of blood followed its withdrawal—showing clearly that in the case or cases examined there was no accumulation of blood in the uterine cavity. Schultze's statement as to the patency of the canal during the pain has been recently confirmed by observations made by Dr. J. E. Burton of Liverpool.[2]

There are other clinical phenomena of which Dr. Hewitt offers no explanation. Some of the most striking instances of benefit from treatment by pessaries are furnished by cases in which the uterus is quite straight, being simply retroverted, not retroflexed. No theory as to obstruction of the canal, or strangulation of the vessels by flexion, helps us here. The removal of symptoms must have resulted from the removal of some condition quite other than flexion. The promptness of the relief following mechanical treatment shows that it is a condition associated with the displacement, and the number of cases of retroversion which do not cause trouble shows that it is a condition not present in every case. I believe the elucidation is to be found in the disposition of the utero-sacral ligaments. Dr. Hewitt, although he condemns this as "mere trifling," yet has no explanation of these cases to put in its place. Again, there is, to use Dr. Hewitt's words, the "liability to greater congestion in retroflexion than in anteflexion cases." This needs explanation, but Dr. Hewitt offers none. Anteflexion is frequently met with so acute that the lower part of the cervix is parallel with the body of the uterus, while retroflexion so extreme as this is uncommon. If congestion depended on the flexion, it ought to be in proportion to the acuteness of the bend, which it is not, as Dr. Hewitt, in the sentence quoted, practically admits.

(To be concluded.)

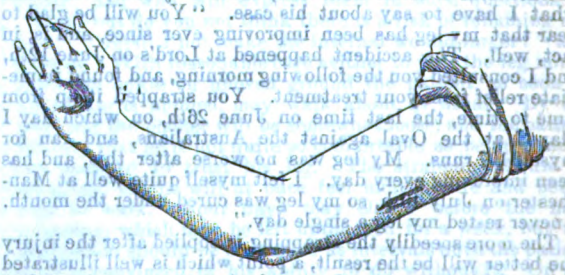
CASE OF DOUBLE WOUND IN THE SAME LIMB FROM A SINGLE GUNSHOT.



By BRIGADE-SURGEON G. L. HINDE, A.M.D.

THE following case of conservative surgery presents many points of interest:—

Private R. S——, 7th Dragoon Guards, aged twenty, when at rifle practice, seeing his carbine, which he had lent to a comrade, lying on the ground, the hammer at full cock, and not knowing it was loaded, proceeded to ease the spring. To do this he leaned his left hand on the muzzle and pulled the

trigger with his right thumb. On the discharge of the weapon he was severely wounded both in the hand and in the upper arm. The arm and hand were temporarily tied up with handkerchiefs, and the man was brought to the Station Hospital, Shorncliffe, where it was found that the bullet had perforated the hand in its centre through a small circular wound. The whole integrity of the hand seemed to be loosened, and there was a large irregular opening at the back, extending from the metacarpo-phalangeal joint of the ring finger obliquely across to the centre of the metacarpal bone of the index finger, and then back to the os magnum. The

second metacarpal bone was gone with the exception of its head; the first and third metacarpal bones were exposed for almost their entire length; and the os magnum was chipped at its metacarpal articulating surface. The extensor tendons of the second finger were also destroyed, the others much displaced. All ragged tissues and those hardened from powder and fire were removed, and the wound cleansed from all clots and débris by syringing with tepid carbolised water, and then packed with lint steeped in carbolic oil, and the whole supported by a light bandage. Further examination showed that the bullet had also perforated the upper arm on the

Digitized by Google

inside, somewhat anterior to the artery, and fractured the humerus at the junction of the middle and lower third, and then passed out at the back of the arm, the entrance wound being small, the exit irregularly circular, about two inches in diameter, with everted edges, and having a mass of muscle protruding. Inside the integuments a large cavity was found lined with broken up tissues mixed with fragments of bone. One large piece of bone, which appeared to be of almost the entire circumference of the shaft, and one inch and a half long, having plenty of attachments, was brought into position between the fractured ends of the shaft, so as to give a base for the deposit of callus, it being hoped that it would have sufficient vitality not to become a foreign body. Having removed all spiculæ, ragged fascia, and muscle, the cavity was cleansed from clots by syringing, and filled from both sides with lint saturated with carbolic oil; the limb was then placed on a jointed arm-splint in a semiflexed position. All the wounds were covered with carbolised gauze, and kept moistened with carbolic lotion. There was very little swelling, and little constitutional disturbance for the following five days. On the sixth day the patient complained of burning pain in all the wounds, suppuration being fully established. I proceeded to dress the wounds of the hand. On removing the plugs profuse hæmorrhage occurred, apparently from both palmar arches; so, after consultation, it was decided to tie the brachial artery. The operation was carried out immediately. A ligature was placed upon the artery where most superficial in its upper third, and all wounds were dressed with carbolic oil. Catgut ligatures were tried, but, being found unsound, silk was used. The night following the temperature went up to 102·4°. After a purgative enema the temperature began to decrease. The next morning it was only 101·2°. With the aid of cotton-wool the hand and arm retained natural warmth. All the wounds were dressed daily antiseptically. The ligature came away on the tenth day, and steady progress continued. Some slight changes in treatment were required—such as strapping a gaping wound, and a short febrile attack combated—otherwise it might be said that the treatment was uniformly antiseptic and simple. On this (the 108th) day the state of the limb was as follows:—The elbow had a good motion, but its action was limited owing to cicatrices being adherent to the biceps and the triceps muscles. All motion was complete in the wrist-joint. Motion in joints of fingers good. Apposition with thumb returned under passive motion and daily practice. The second finger had lost all power, but retains its shape; all joints perfect under passive motion; it may require operative interference hereafter. The upper arm is shortened about three-quarters of an inch. The above drawings show the relative position of wounds.

NOTES OF A

CASE OF POST-HEMIPLEGIC HEMICHOREA ASSOCIATED WITH INSANITY.

BY C. THEODORE EWART, M.B., M.CH.

SENIOR ASSISTANT MEDICAL OFFICER, FISHERTON HOUSE ASYLUM, SALISBURY.

ALTHOUGH the following notes are meagre, they may be of some slight clinical interest.

E. M——, cab-driver, aged forty-two, was admitted into the Fisherton House Asylum on March 29th, 1884. The patient is a fairly well nourished man suffering from aphasia, and has extreme difficulty in speaking. Hesitation, delay, irregularity, and jerkiness are noticed in his articulation, "from the incoördinate action of the cerebral centres, whose function it is to translate thought into the corresponding motor acts of speech." I understand that on two occasions he has lost consciousness, the symptoms being of an apoplectic nature. There is no history of hereditary predisposition to insanity. His mind is depressed, and he is irritable, obstinate, and taciturn. His perception is defective, indicative of failure of brain power, and he does not seem capable of conceiving an exact idea of his situation. He has never had rheumatic fever, and there is no cardiac mischief. There are violent choreic movements of the right arm, and, though to a much less degree, the right leg. The left arm is not affected by spasm, but is partially paralysed. The movements on the right side are so severe that his face is bruised from the self-inflicted wounds, and his hand hurt from striking against his bed. The force is such that an attendant's face coming in the line of motion his eye received a severe contusion. The upper right forearm is an inch larger than the left, and this increased muscular development must be due to the constant movement, which only ceases during sleep. The muscles of the face are very much contorted. By the influence of the orbicularis and neighbouring muscles the mouth is drawn into odd positions. The forehead is wrinkled, and the whole face presents the most contradictory expressions; in fact, there is a "delirium of the sensori-motor ganglia." A certain amount of anæsthesia is present, but there is no great loss of tactile sensibility in the affected hand, which grasps with greater firmness than the other. The sense of hearing is blunted, but sight, taste, and smell are not. Mastication and deglutition are imperfectly performed. When attempting a definite movement the spasmodic action is much exaggerated. The hand is alternately supinated and pronated, extended and flexed, and so combined as almost to defy description. Control over the bladder and rectum is retained. No albumen in the urine. Knee-jerk and ankle clonus exaggerated.

Treatment.—Cod-liver oil was ordered three times a day. Twenty minims of the tincture of Indian hemp combined with twenty grains of bromide of potassium were prescribed every four hours, and a draught containing thirty grains of chloral hydrate and ten grains of bromide of potassium was given at bedtime to procure sleep. As soon as the spasmodic action ceased he was put on fifteen-drop doses of the tincture of perchloride of iron. The bowels were kept open. The diet consisted of beef-tea, milk, eggs, and brandy. The right arm was bandaged to his side; at first when this was done the lower extremity of the same side was violently affected, and had also to be bound. In a fortnight he was able to button and unbutton his coat, and could dress himself; in another week he could converse in an intelligible manner. He carried his hand in the pocket of his coat, so as to prevent its disordered movements. He is now able to execute any intended movement, but in a slightly tremulous manner, and there is no difference in the size of the two forearms. There is still a fidgety manner, which shows itself in grimaces, needless haste, and a want of precision.

Remarks.—I consider from the symptoms that the hæmorrhage must have occurred in the corpus striatum, optic thalamus, and medulla oblongata. Raymond says that in six cases where a post-mortem examination was made the lesion was situated in every instance in the posterior part of the optic thalamus, and involved the fibres of the internal capsule. The lesions which have been found to give rise most frequently to hemichorea are yellow cicatrices, the remains of old hæmorrhages, or softening from occlusion of the posterior external optic artery, although choreiform movements have occasionally been observed during the growth of tumours in this region. The symptoms do not appear to depend upon lesion of the optic thalamus itself, inasmuch as they are never present unless some of the fibres of the sensory peduncular and pyramidal tracts are injured; nor does it even appear to be caused by injury of the sensory fibres, since hemianæsthesia with bilateral hemianopsia may be present without being associated with choreiform movements. It would seem, therefore, that injury to some of the fibres which lie in front of the sensory pedunçular tract is the cause of hemichorea (Ross).

SCHOLARSHIPS.—At the Westminster Hospital Medical School the Fence entrance scholarship of £40 per annum, tenable for two years, has been awarded to Mr. James Dickinson; and the entrance scholarship of £20 per annum, tenable for two years, to Mr. George Thomas James.—At King's College the entrance scholarships have been awarded as follows:—Warneford scholarship of £75 each to Messrs. A. S. Sandifer and T. B. Beach; Sambrooke Exhibition of £50 to Mr. H. S. Ballance; and Clothworkers' Science Exhibitions of £50 and £25 to Messrs. T. G. Brodie and C. W. Atkinson.

THE portrait of the late Duke of Albany, by Mr. Walter Goodman, recently exhibited in the Guildhall Galleries, has been purchased by the Secretary of the National Hospital for the Paralysed and Epileptic, Queen-square, Bloomsbury, on behalf of the Board of Management of that Institution.

ST. BARTHOLOMEW'S HOSPITAL.

THREE CASES OF EPITHELIOMA OF THE TONGUE AND FLOOR OF THE MOUTH.

(Under the care of Mr. MORRANT BAKER.)

FOR the following notes we are indebted to Mr. Toller, house-surgeon.

CASE 1. *Epithelioma of the Tongue; Operation through Cheek; Removal by Ecraseur; Recovery.*—Henry H——, aged fifty-three, builder, was admitted to Darker ward on Dec. 14th, 1883, suffering from epithelioma of the tongue. Six years ago he first noticed a soreness in the centre of his tongue, without being able to assign any apparent cause. He consulted a medical man, and after using a gargle appeared to obtain relief for a time, and for two years slowly improved, although unable to take solid food; from that time the improvement continued until four years ago, when he felt well, and was able to eat solids. In August, 1883, the soreness again appeared, when he again sought advice, and after the application of a gargle and nitrate of silver his trouble rapidly increased. There was no family history of cancer, and no syphilitic history. The patient had been subject to gout; the urine was normal. He had smoked to a great extent up to twenty-seven years of age, but since that time very little.

On admission, on the right side and posterior two-thirds of the tongue there was an indurated, ragged ulcer, with sloughing, everted edges extending across the median line, and involving part of the left half of the tongue. The tongue was fixed, and could not be protruded beyond the teeth, which in the right lower jaw were in a carious condition. An enlarged lymphatic gland could be felt below the angle of the jaw on the affected side.

On Dec. 19th Mr. Morrant Baker removed the tongue. The cheek on the right side was transfixed and the incision carried forwards one inch and a half to the angle of the mouth. Each half of the tongue was removed separately by the écraseur. A hard mass could still be felt extending back as far as the base of the epiglottis and involving the right tonsil; this was drawn forward by a silk suture and a ligature passed behind the mass, which was then removed with the scissors, a part of the soft palate and right tonsil being involved in the removal. The edges of the cheek were then brought together with harelip pins.

The patient had a fair night. Next morning the temperature was 101°. Milk, eggs, and brandy were given at intervals through an elastic tube and funnel. The mouth was constantly syringed with Condy's fluid.

On Dec. 28th he was going on well, and the wound was healing. He could swallow easily without the tube. He had a slight attack of gout.

On Jan. 11th he was discharged well.

CASE 2. *Epithelioma of the Tongue and Floor of the Mouth; Removal of the whole of the Tongue, Floor of the Mouth, Submaxillary Glands and Anterior Portion of Lower Jaw; Recovery.*—George B——, aged fifty, painter, was admitted to Harley ward on Feb. 14th, 1884, suffering from epithelioma of the tongue and floor of the mouth. The patient had noticed a small swelling beneath the tongue in the centre of the floor of the mouth for two months which had rapidly increased, causing great pain and inability to masticate solid food.

On admission the growth occupied the whole of the under surface of the tongue and floor of the mouth, extending forwards to the symphysis of the jaw which it invaded and posteriorly involved the gums nearly to the base of the tongue. The surface was irregular, deeply ulcerated and hard, and was partially covered by a thick greyish-white slough. The edges were raised and indurated; the tongue could not be protruded, but could be moved freely in the mouth. The submaxillary and other glands were enlarged. The salivary flow was greatly increased and trickled from his mouth. The urine showed a faint trace of albumen. No gouty or syphilitic history could be obtained.

On Feb. 27th Mr. Morrant Baker proceeded to remove the morbid growth. A vertical incision from the centre of the lower lip to the under surface of the symphysis was made, the parts were then reflected back for an inch and a half on either side by means of an incision along the lower border of the jaw at right angles to the previous incision. The alveolar process being invaded, was then removed by the aid of Dr. Bonwell's surgical engine. It was found, however, that even this procedure did not permit the whole of the disease to be satisfactorily removed; a portion therefore of the whole thickness of the horizontal ramus of the jaw was removed from about the first molar on one side to the second bicuspid on the other, the bone having been first deeply notched by the circular saw and the section completed with bone forceps. The structures forming the floor of the mouth being affected were removed, including the submaxillary glands of both sides. The tongue was then divided from the tip to the base and each half removed by the scissors; the base of the tongue was then fastened to the floor of the mouth, the lip wound was then brought together by harelip pins and dressed with sanitas oil lint.

On the 28th the patient passed a restless night, notwithstanding three subcutaneous injections of morphia, one-sixth of a grain each time. He was fed through an elastic tube and funnel without discomfort. Next day the wound of the lip was found to be healing by first intention.

On the 29th there was some swelling at the base of the tongue; the tube could not be passed for two days, during which time he was fed per rectum. The mouth was dusted freely with powdered iodoform, and syringed frequently with Condy's fluid.

On March 24th he took liquid food from a feeder. The wound was healed, with the exception of a fistulous track leading from the submental region into the mouth, the remains of a part of the wound which had been utilised for drainage during the after-treatment. The patient was discharged on April 4th.

CASE 3. *Epithelioma; Removal of the Right Half of the Tongue through an Opening in the Cheek; Rapid Recovery.*—Mary D——, aged thirty-two, married, was admitted to Sitwell ward on March 27th, 1884, suffering from epithelioma of the tongue. Seven months previously she noticed a small swelling on the right half of the dorsum of the tongue, which was painful and gradually increasing in size. There was no family history of cancer; all her children were healthy, the youngest being six months old.

On admission the growth involved the right posterior half of the tongue, extending to, but not beyond, the median line. The tongue could not be protruded beyond the lips. There was a slight glandular enlargement at the angle of the jaw of the same side.

Mr. Morrant Baker removed the right half of the tongue on March 29th. The right cheek was transfixed about two inches behind the angle of the mouth, and the incision carried forwards into the mouth; the tongue was then divided from tip to base, and the right half removed by the cord écraseur. The cheek wound was brought together by harelip pins.

The patient had a fair night. The wounds were dusted with iodoform and syringed with Condy's fluid every few hours. Nourishment was administered by the elastic tube.

Eleven days from the operation the patient was discharged, the mouth looking very well, and the wounds quite healed.

Remarks.—Mr. Morrant Baker remarked that these cases were all of them examples of advanced epithelioma of the tongue and neighbouring parts, in which removal was undertaken, more for relief from present and future pain than with any expectation of a long freedom from recurrence. In the event of the operation being followed by recovery, it was anticipated that there would be great relief from the severe pain produced by gradually increasing pressure on the nerves, especially the gustatory; and that, in the event of recurrence, the pain would be very much less than in the case of no operation having been performed. In all the cases there might be a fair expectation that the ulcerating tumour would never reach the same dimensions as originally, and that not improbably recurrence might not happen to any extent in the mouth, but in the lymphatics which were out of reach at the time of the operation. In cases of removal of epithelioma of the tongue at an early stage it frequently happened that in the event of return of the

Digitized by Google

disease in the cervical lymphatics the mouth remained quite free, and therefore the removal was the means of infinite relief to the patient. Early removal could not be too strongly insisted upon, and in a very large number of cases surgical interference is actually necessary in order to give as much relief as possible to the sufferer.

DEVONSHIRE HOSPITAL, BUXTON.

HEREDITARY CONGENITAL MALFORMATION OF HANDS AND FEET.

FOR the subjoined notes we are indebted to Mr. W. J. Tilley, assistant house-surgeon.

The following case is of peculiar interest, because similar malformations exist in several members of the patient's family.

C. S——, aged forty-four, single, was admitted with rheumatism. She was a strong healthy-looking woman and well developed, except in the extremities of both upper and lower limbs. The hands were normal, except for the absence of the two terminal phalanges of all the fingers. The feet, with the exception of the toes, were well formed. The right had four toes, the inner two being normal; the third contained two bones (metatarsal phalanges), the two terminal phalanges being absent; the fourth was very small and had but one minute bone. The left foot also had but four toes, the two inner being normal, the third contained one bone only. The fourth presented a slight longitudinal groove, suggesting the fusion of the two toes, but only one metatarsal phalanx was present.

The patient was one of a family numbering ten. The condition of the other nine members was given by the patient:—First child, male. Fingers and toes normal. Second child, male. Fingers and toes normal. Third child, female (patient). Condition described above. Fourth child, male. Fingers all short; toes normal. Fifth child, female. Two fingers (index and middle) normal. The others had but one bone; toes normal. Sixth child, female. Index and middle fingers have two bones and small nails on each; ring and little fingers have but one bone in each; toes normal. Seventh child, female. Fingers and toes normal. Eighth child, male. Fingers all short; toes normal. Ninth child, male. Fingers and toes normal. Tenth child, female. All fingers short; toes normal.

The patient's father had short fingers (but one bone in each). Several (paternal) uncles had deformities of both hands and feet, but patient was uncertain what the exact condition was in each case, as no detailed account was taken. Two of the patient's sisters are married, No. 5 and No. 7 in the list. No. 5, who had malformed fingers, has three children; two girls are free from deformity; the third is a boy, with ring and little fingers containing but one bone. No. 7, whose fingers were normal, has several children without deformity. One of the patient's uncles is married, and has children with deformed fingers. One of these children, a daughter, is married, and her fingers are all short; she has four children, two boys and two girls, all having short fingers. The patient has been told by her parents that her paternal grandmother had short fingers.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Dysenteric Abscesses in Liver.—Hæmophilia and Purpura.—Tabes Dorsalis with Perforating Ulcer.—Alcoholic Paralysis.

THE first ordinary meeting of the new session of this Society was held on Tuesday last, Mr. George Lawson, a Vice-President, in the chair. The meeting proved to be full of interest, the papers and discussion were good, and the microscopical specimens all that could be desired.

Dr. CHARLEWOOD TURNER read a paper on Dysenteric Abscesses in the Liver. In the first case there were two abscesses of old date and several smaller abscesses of recent formation. The patient was a man aged thirty-four, who on his voyage home from Singapore felt pain about the hypochondrium, and had frequent vomiting and severe diarrhœa with bloody and slimy stools. At Port Said he was sent into hospital, a hepatic abscess was tapped and five ounces of thick pus withdrawn. His health somewhat improved, but when again on board the dysenteric symptoms returned. When he reached London he was taken into the London Hospital, where he died two days after admission. He had had pain all over the abdomen and dragging sensations in the rectum, with all the usual symptoms of dysentery and hepatic suppuration. The liver was enlarged but not tender; there were marked anæmia and signs of pleurisy at the base of the right lung. At the autopsy extensive destruction of the mucous membrane of the colon was discovered, with some extravasation of fæcal matter into the peritoneal cavity at this site. The intestines were coated in places with lymph, and patchy hyperæmia was also visible. The coils of the bowels were slightly adherent. In the anterior part of the liver a large abscess, which occupied the quadrate lobe and almost destroyed it, was found. A second large "primary" abscess was seen in the middle of the upper surface of the left lobe; this was smaller than the first and of the size of a hen's egg. The two large abscesses were bounded by thick fibrous walls, had a smooth lining membrane, and were connected with neighbouring structures by firm adhesions. The next important feature was the presence, scattered all over the surface of the right lobe, of small abscesses and areas of actual or commencing suppuration. There were none of these in the left lobe. There was no cirrhosis of the liver; the lungs were congested and œdematous; the right lung was adherent; the kidneys were enlarged and weighed sixteen ounces; the spleen weighed four ounces. Dr. Turner said that the features of the case were entirely in accordance with the generally accepted views on dysentery and hepatic abscess. A point to explain, however, was the limitation of the multiple abscesses to the right lobe of the liver. Septic micro-organisms probably played a part in the infection of the liver from the disease of the bowels. No doubt the presence of other conditions than mere absorption of poison was necessary in order to interpret the peculiar features of the case. A condition affecting the nutrition of the right lobe of the liver, and which so placed it at a disadvantage with the left lobe, was found in the state of the right branch of the hepatic artery at the point where the cystic artery was given off; here it made a sharp turn backwards. He thought that the association of fresh hepatic disease with the commencement of a fresh outbreak of disease of the bowels was of a causative kind. Infective micro-organisms in the follicles of the colon or in the contents of the bowel were the probable agents in producing the disease of the liver. Local conditions were of chief importance in determining the occurrence of these abscesses, and the possibility of the partial dependence of the primary abscesses on some local injury, such as a blow in the epigastrium, was speculated upon. As an illustration of these remarks, a case of traumatic aneurysm of the renal artery as the result of an injury to the abdomen was cited. Heubner and others had discussed the causes of the recrudescence of the disease after apparent recovery. The restoration of the absorptive function of the mucous membrane of the colon might play a part in the renewal of hepatic disease.

Dr. CARRINGTON read notes of a case also of Dysenteric Abscess of the Liver. The first case was that of a man, aged twenty-two, a Portuguese sailor, who was admitted on August 6th into the Seamen's Hospital, Greenwich, in a state of high fever. Marked wasting, rigors, and other usual signs were present, and an exploring needle allowed pus to be withdrawn. At first the diagnosis between empyema and hepatic abscess was impossible. A free incision into the swelling in the lower aspect of the right axilla let out two or three pints of the peculiar grumous fluid found in hepatic abscess. The fever continued, and the patient gradually sank three weeks after admission. At the necropsy the liver was much enlarged, and two large abscess cavities were seen in the upper part of the right lobe of the liver. One of these had been tapped, and the other contained a quarter of a pint of thick pus. Besides the large abscesses, the whole substance of the liver was riddled with many small abscesses, about the size of a small pea, or less; in some of these areas a small vessel like a vein could be detected. Deep ulceration extended throughout the whole of the large intestine. From his experience he could say that this association of small with large abscesses in the liver was comparatively rare. The walls of the tropical abscesses were very thick, and proved its older date. If these abscesses were due to septic absorption what was the source of the infection? The

Digitized by Google

multiple abscesses were found in every part of the liver, and as no track of disease could be found in the portal vessels, he suggested that the lymphatics were the carriers of the infective material.—Dr. EWART referred to two patients suffering from hepatic abscess, both of whom had served in Egypt; one, however, recovered, and the other died. The first case was that of a man aged twenty-eight, who recovered after aspiration. The other patient, also a man aged twenty-eight, was suddenly seized with acute pain in the abdomen and a feeling as of something having burst. Aspiration was practised two or three times, and finally a free opening was made into the hepatic abscess; he finally succumbed after having suffered for two weeks before death from dysentery. The liver was found to be riddled with small abscesses, the appearance of which suggested necrosis rather than free suppuration. The large abscess had an indurated wall. The appearance of the colon, which had a pale, waxy, sodden, necrotic aspect, was almost precisely like that of the liver. He thought that the infection must have proceeded along the portal vessels.—Dr. CURNOW referred to the question in saying that the views of Dr. George Budd on the causation of tropical abscess—viz., that it was of pyæmic origin from dysenteric disease—were fast gaining ground in England, notwithstanding the influence of Dr. Murchison's work. In his (Dr. Curnow's) experience there never had been a case which was not dysenteric in origin; the evidence of dysentery rested on post-mortem examination, the actual presence of the classical symptoms, or a clear history of it. So that he now doubted whether the view, as held by many Indian surgeons, that no direct relation existed between the two diseases, was really correct.—Dr. SAMUEL WILKS, whilst agreeing with the remarks of the previous speaker, said that there must be strong grounds for the views held by surgeons of large Indian experience. Sir Joseph Fayrer, and a French surgeon who had had much experience in Algeria, were sure of the occurrence of hepatic abscess apart from dysentery. In mild climates, too, ulceration of the intestines frequently took place without hepatic abscess resulting; so that climate probably had some influence in the causation.—Mr. GEORGE LAWSON said that, surgically, the difficulty was to treat the multiple abscesses.

Dr. WICKHAM LEGG brought forward some specimens illustrating the anatomy of Hæmophilia. About three years ago he had shown specimens of the mucous membrane and skin taken from a fatal case of hæmophilia, in which no alteration from the natural state could be discovered. Those specimens and some new ones had been investigated by Dr. Klein, who also concluded that no morbid changes were present. The case of a little boy, aged thirteen, who died from epistaxis, was next referred to. He had had bleeding from many parts and swelling of the joints. This was the sixth case in which the tissues had been examined. In four cases the examination showed nothing abnormal. In one case reported by Lindwurm the skin was such a remarkable specimen of ichthyosis that the patient had not a sound place from top to toe, and Dr. Legg was inclined to reject this instance. The other was a case of Dr. Percy Kidd's, in which extensive changes in the vessels were discovered. Dr. Legg next handed round specimens of the joints in hæmophilia. This was only the fourth case in which the arthritic disease had been demonstrated after death. Poncet of Lyons and Sir William Jenner had examined two, and he had placed the other two on record. The first stage of the disease was an extravasation of blood into the joint, and the cartilages remained sound. In the second specimen the synovial membrane was seen to be rusty-coloured, and slight erosion of the cartilage of the femur was present. In the third specimen the synovial membrane was of a deep-red colour, and the cartilage was deeply eroded and destroyed. It was thus shown that the arthritic disease was caused by the extravasation of blood.

Dr. THEODORE ACLAND showed specimens of the Thymus Gland in cases of Hæmophilia and Purpura. The nature of the changes were doubtful. He described spheroidal masses of concentric appearance which were many times the size of the concentric corpuscles of Hassell. The first case was that of a boy aged 7, who had sustained a wound of the tongue by which death from loss of blood was caused. There could be no doubt that the boy was a genuine bleeder; he had one brother who suffered from frequent epistaxis, and another who had bled from the gums and bowels. The patient had had many petechiæ and bruises. The three girls of the family were healthy; a grandfather on the mother's side had suffered from the malady. The blood after death was profoundly altered, being much paler and more watery; the white corpuscles were in excess. All the tissues were perfectly natural with the exception of the parotid and submaxillary glands, sections of which presented numerous small darkly stained cells in the acini; probably the result of irritation from the lingual wound. In the thymus gland round spherical masses, which were probably related to the striated corpuscles of Hassell, and which were bounded by a layer of flattened elongated cells and contained epitheloid cells having a faint nucleus, were to be seen. The fibrous tissue was much increased in many places. The gland was of considerable size. Whether these curious bodies were stages in the evolution of striated corpuscles he could not state. He had examined several thymic glands from healthy children with a negative result. It was significant that he had found these bodies in purpura and hæmophilia. The case of purpura was that of a girl with pelvic abscess in which the purpuric eruption was almost universal.

Dr. WICKHAM LEGG read notes of a case of Purpura, which two years before death had had a hard chancre. The man had been a heavy drinker, and had been ill and sparely fed. When first seen, the purpuric eruption, which came out in greater abundance one month before death, was associated with swelling of the joints of the knees, ankles, and of the hand. About five days before death a recrudescence of the purpura set in in the form of urticarial wheals, into which, within a few hours, hæmorrhage occurred. The purpura began at one elbow, and next appeared symmetrically at the other elbow, and finally became widespread. The patient died exhausted by diarrhœa. At the necropsy there was severe ulceration of the intestines, extending all along after the first four feet from the duodenum had been passed. The occurrence of intestinal ulceration was not at all uncommon in cases of fatal purpura. On microscopical examination a large amount of corpuscles in all the tissues of the skin were found to be extravasated in and around the sweat glands and between the vesicles of the fatty tissue. Besides the scattered red corpuscles, there were masses of red discs; some of the corpuscles had one end rounded and the other irregularly shaped. The blood proceeded from ruptured bloodvessels. There were changes in the papillæ, and the vessels under the epidermis were distended and dilated. The arteries were greatly thickened, especially the inner and middle coats, abundant nuclei being seen on section. In the villi of the intestine a large number of hæmorrhages had taken place, and in places areas of infiltrated white corpuscles were to be seen. Scurvy was probably not the cause of the disease; there were no swollen gums, and the patient had not undergone any very great improvement by treatment. The purpura of alcoholism was negatived by the absence of cirrhosis, and that of rheumatism was supported only by the swollen joints, which were probably of hæmorrhagic origin. Syphilis remained as the probable cause. In cases of erythema nodosum and of purpura urticans (Bateman) we had somewhat similar appearances, but there had been no burning or itching sensation at first in Dr. Legg's case. The presence of considerable disease of the vessels of the skin in syphilis was not impossible, and reference was made to the case recorded by Dr. Wilson Fox, in which fatal purpura was probably of syphilitic origin. In all his cases Dr. Legg had found no micro-organisms; Ceci, working with Klebs of Prague, in 1881, had described micro-organisms, as had also Barthelemy of Paris, and there were altogether only a few cases in which micro-organisms had been discovered.—Dr. BUZZARD agreed with Dr. Legg that the case was not one of scurvy, but he had never seen such a condition as the result of syphilis. In alcoholic patients he thought such changes in the vessels were to be found. He referred to one case in which the vascular changes were exactly similar to Dr. Legg's specimen.—Mr. VICTOR HORSLEY said that the concentric bodies which Dr. Acland had described recalled the descriptions of Affanasieff, who believed that such structures were the result of endarteritis of small vessels; there was every stage between those bodies and Hassell's corpuscles. The alliances of the concentric bodies to specimens of psammoma were also indicated.—Dr. PERCY KIDD referred to the case of hæmophilia which he had published in the Medical and Chirurgical Transactions for 1878. There were extensive changes in the veins and capillaries not only of the diseased parts, but also of remote vessels like the vasa vasorum of the aorta and vena cava. He thought that an affection of the wall of the vessel would probably be found to be the real cause of hæmorrhage.

Mr. PEPPER read a paper on a case of Tabes Dorsalis asso-

Digitized by Google

ciated with Perforating Ulcer of the Foot. In May, 1883, the patient, a woman aged sixty years, first came under notice. She had been in India, and had had ague of a severe character. There was no history of alcoholism, syphilis, or injury. There was very decided numbness of the second toe on the right foot. She had been successfully operated on for double cataract at the Middlesex Hospital. There were "stinging" sensations all over the body; and a painful corn had developed in the sole of the right foot. Here there was to be seen a heaped-up mass of epithelium. Decided anæsthesia of both feet was detected, and there was absence of the knee-jerks. The gait was not attended with any noticeable ataxia. There was partial ptosis on both sides. Later on very acute inflammation of the skin over the dorsum of the foot occurred, and the inflammation rapidly went on to gangrene. Throughout the case the urine was normal. The patient left the hospital on June 10th. Later on, June 18th, she was taken into the hospital, and the foot was removed with strict antiseptic precautions. For the space of four days there was no sign of local disturbance, but after that time the heel flap became purple and sloughed. Thence onward the case went rapidly to the bad; bedsores of surprising acuteness, and attended with no previous sign of inflammation, formed, turned black, and the tissues speedily disintegrated. There was generally no fever, and 101° F. was registered only once.—Dr. SILCOCK read the notes of the morbid appearances. The sinus in the stump ran up on the inner side of the tendo Achillis, and much pus infiltrated the tissues upwards as far as the popliteal space. The lower end of the tibia was necrosed. The brain was sound, with the exception of the atheromatous vessels; the spinal cord showed grey degeneration of the posterior root zone. The mitral valve was much diseased. The liver and kidneys were toughened, but the other organs were normal. On microscopical examination the whole cord was found to be affected with diffuse sclerosis, which was not limited to special parts. Around the grey matter, more markedly in the posterior columns, there was much thickening of the neuroglia. The posterior cornua and posterior roots were also involved, and in the grey matter some spaces bounded by ragged irregular walls and having a reticular or granular appearance, sometimes homogeneous, were to be seen. In places what seemed to be altered myelin was observable, but the clear spaces just described in the grey matter were probably due to recent inflammatory softening, and were almost exactly like those to be seen in a case of tetanus reported by Mr. Pepper. The bloodvessels of the cord were notably thickened. In the posterior root zones no normal nerve fibres were observed. The chief part of the changes was probably of considerable standing. Reference was next made to the state of the sciatic and internal popliteal nerves; there was evidence of hyperplasia of the endo- and epi-neurium, and the myelin had segmented, whilst the axis cylinders were much altered. The changes described by Messrs. Savory, Butlin, Déjerine, Pitres, and Vaillard, as occurring in cases of locomotor ataxia associated with so-called trophic lesions, were compared with those present in the case narrated, and the conclusion was come to that the trophic lesions were, with far more reason, attributable to structural alteration of the peripheral nerves than to changes in the spinal cord.—Dr. SAMUEL WILKS objected to the use of the term "tabes," which had no definite meaning.—Dr. BUZZARD inquired whether the morbid alterations in the nerves had been traced from the periphery to the centre. The changes described by Déjerine, Pitres, and Vaillard were confined to the actual periphery of the affected nerves, and if the changes were continuous from the periphery to the central portions, the observations of Dr. Silcock would be a valuable complement. He could not help suggesting the idea of the possibility of the dependence of the neural changes on the thickened condition of the vessels of the periphery of the arterial system.

Dr. PAYNE and Dr. F. SÉMON showed a living specimen of Rhinoscleroma, and Dr. ORMEROD a case of Scleroderma.

Dr. W. B. HADDEN read a paper on Two Fatal Cases of Alcoholic Paralysis. A married woman, aged thirty-three, was admitted into St. Thomas's Hospital under the care of Dr. Harley on April 7th, 1883. She had always been a heavy drinker, especially for the last twelve months. She had been married thirteen years, but had never been pregnant. Four months ago she began to have pain in the head and twitchings of the face and hands. She had fallen down unconscious several times and was said to have epilepsy. She had had mental symptoms with loss of memory for three months. Ten days before admission she lost the use of her legs. On admission the legs and thighs were œdematous and she had retention of urine. The legs were almost powerless and the knee-jerks absent. Delirium set in. The lower edge of the liver could be felt two inches below the costal arch. Sensation was fairly good. The delirium continued; the paralysis of the legs and arms became more marked, and the muscles failed to respond to the strongest interrupted current. Sensation later on was noticed to be decidedly delayed in transmission. There was slight fever for a few days before death. At the necropsy there was acute tuberculosis of nearly all the viscera. The brain, medulla oblongata, and spinal cord were healthy to the naked eye, and no change was detected microscopically. The nerves were not examined. The second case was that of a woman, aged forty-two, who was a patient of Dr. Stone's. She had had seven children, six of whom were alive. Two months ago she had flooding after a miscarriage. About a year before admission she became delirious on board ship. It was ascertained that she had been drinking freely and had had delirium tremens. Weakness of the legs came on three months before admission, and for the last six weeks she had not walked without assistance. On admission complaint was made of severe pains, which started in the great toe and passed up to the hip, coming on in paroxysms. The legs and arms felt as if they were being screwed. There was no loss of control over the bladder and rectum. She slept very little, and had delusions at night. The arms were much wasted, and there was "dropped wrist" on each side. All the muscles of the arm were weak, but the extensors more than the flexors. The reflexes were absent. The muscular sense and sensation were normal. There was great weakness of the muscles of the trunk. The voice was feeble, and she had a high-pitched cough. No anæsthesia of the trunk was detected, and there were no superficial reflexes. The legs were extremely emaciated, were kept drawn up, and were very painful when touched or moved. Before death a number of bullæ appeared on the limbs. The signs of broncho-pneumonia were present, and also those of cirrhosis of the liver. There was atrophy of the brain in the frontal region. In the spinal cord the grey matter was obscure in the cervical and upper dorsal regions, and lower down the cornua seemed slender and pale. The right sciatic nerve showed the nerve tubules to be much reduced in size; the endo-neurium and neurilemma were much thickened, but not the peri-neurium; the diminution affected chiefly the medullary sheath of the nerves. In many parts there were deeply stained areas of thickened connective tissue, and the axis cylinders were deprived of their medullary sheaths. The changes were more advanced in the centre of the bundles, where there were large bundles of newly formed connective tissue, but no segmentation of the myelin. The changes in the cervical and dorsal regions and the granular appearance of the medullary sheaths were probably artificial and post mortem. These were the signs of peri-neuritis. The right median nerve showed similar changes, though less marked. In the muscles there were deeply stained nuclei which in some parts took the place of the muscular fibres; the muscular corpuscles were increased, and some of the muscular fibres were atrophied and granular. These observations showed that alcoholic paralysis was not of spinal origin, and agreed with the views that the cause was a disease of the peripheral nerves as found by Lancereaux, Dreschfeld, and others. In his case, however, the change was not a primary neuritis. Dr. Reginald Thompson had recorded in 1868 cases in which there was atrophy of certain nerves and early fatty changes in the muscles, with patches of softening in the cord, but no microscopical examination had been made. The change in the liver, nerves, and muscles was identical. Reference was made to a case in which nystagmus occurred, and to another in which motor paralysis of the arms and legs with nystagmus, atrophy of the left half of the tongue, and paralysis of the right recurrent laryngeal were associated. The hypoglossal nerve was found to be atrophied and the liver was cirrhosed; there were signs of acute tuberculosis in all the organs. The presence of cirrhosis of the liver and acute tuberculosis in combination with cases of alcoholic paralysis was frequent, and possibly not without significance.

The following card specimens were shown:—Dr. Hale White: Ulcer of Stomach with Secondary Changes in the Pancreas. Dr. Mansell Moullin: Vacuoles in Liver. Mr. John Hopkins: Bones and Joints in Locomotor Ataxia.

MIDLAND MEDICAL SOCIETY.

A SPECIAL and ordinary meeting of the above Society was held on the 8th inst., the President, Dr. Bodington, in the chair. After the nomination of the officers and members of Council for the ensuing session,

Dr. SAWYER read a paper entitled Practical Comments on Pulmonary Consumption. Briefly reviewing the pathology and clinical features of the various forms of phthisis, he said there were four well-marked varieties of pulmonary consumption—namely, miliary tubercular phthisis, lobular phthisis, lobar phthisis, fibroid phthisis. All these forms might be variously blended in any particular case. He did not believe in the tubercle bacillus. He did not doubt that a certain microscopic organism is to be found in and around tubercular cheesy masses in phthisical lungs and in the sputum of phthisical persons, but he doubted that there is a bacillus which is the veritable essence and infection germ of tubercle. He regarded chronic pulmonary consumption as a chronic inflammatory process. He had never found laryngeal phthisis apart from coexisting pulmonary phthisis. He had found ergot the most trustworthy drug in small and continued hæmoptysis, while he preferred gallic acid in copious pulmonary hæmorrhages. Careful observation of the pulse was of high diagnostic and prognostic value in phthisis. Dr. Sawyer commended chloride of calcium as a good general remedy given in ten-grain doses twice daily after food. He had used several volatile inhalations with success.

Mr. CHAVASSE showed a large Meningocele, weighing eleven ounces, that he had removed from the forehead of a child, aged fourteen months, under the care of Mr. Evans of Sutton Coldfield. At the time of birth the tumour was the size of a small apple, but gradually enlarged until the integument covering it was tense and shining. The case progressed well for twelve days after the operation, when, owing possibly to the eruption of several teeth, convulsions supervened and the child died in five hours.

Mr. SIMON showed a living case of Keloid, also a man suffering from a large Ventral Hernia.

THE GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

THURSDAY, OCT. 16TH.

SIR HENRY ACLAND, PRESIDENT, IN THE CHAIR.

THE Council having resolved itself into committee for the adjourned consideration of the subjects of the preliminary examination of medical students,

Dr. STRUTHERS moved, "That the subjects of the preliminary examination for the registration of medical students be allowed to be passed at one or more examinations."

Dr. FERGUS seconded the motion.

Dr. HAUGHTON said this proposal entirely subverted the intentions of Dr. Humphry. The examination was elementary and paltry enough to be passed at one time, and for a student to pass first in Latin and subsequently in mathematics was to lower the standard still further.

Dr. HALDANE, while agreeing that it was desirable that all the subjects should be passed at the same time, yet thought that if this regulation was not carried, a very small number indeed would pass the preliminary examination. He thought they ought to allow those who failed in certain subjects to be subsequently re-examined in those subjects without again having to submit to the entire examination.

Dr. STRUTHERS said the Council had recognised that principle to the fullest extent in the case of professional examinations. If a man passed his Latin or mathematics well, there was surely no reason for troubling him to pass another examination in those subjects, and that was all that was intended by his motion.

Dr. BANKS agreed with Dr. Struthers in thinking it would be very unfair to the student to oblige him to keep up a knowledge on some subjects that in future life would be of very little use in the practice of medicine.

Dr. STORRAR said if the motion was passed it would be putting the axe to the root of the work in which the Council had been so long engaged. The object they had in view was to narrow their requirements in order to secure thoroughness. It seemed to him to be perfectly reasonable that a lad on leaving school to enter on medical studies should be required to show that he had an intelligent apprehension of the subjects of examination. This system of remanets was nothing more than a bait held out to young men to come up in a state of unpreparedness with a chance of getting through on all the subjects, but passing a few and allowing one or two other subjects to be remanets.

Mr. MACNAMARA said he understood the object of the motion was to divide the examination into two parts, classical and scientific. If a man failed in the scientific branches and was remarkably good in the classic, he thought it would be a great hardship to send him back to work up his classics again; it would be much better for him to study those subjects in which he was weak. He thought there was a great deal in Dr. Struthers' suggestion, and should vote for it.

Dr. HAUGHTON said if this resolution was passed it would make their preliminary examinations even more contemptible than they were at present. To say that a schoolboy could not pass the first book of Euclid and Latin in the same examination was to say that he was of a very low type indeed.

Dr. HERON WATSON said the result of passing the resolution would simply be that a person who could not pass in one of the subjects would go back and cram in the subject, so that his eventually passing would be no indication of his having been properly educated.

Dr. AQUILLA SMITH said that allowing students to pass any examination by instalments was a very great evil, and the practical effect would be that they would drop the subjects in which they had passed and consider that they had done with them for ever.

Dr. FERGUS thought, on the contrary, that instead of this resolution lowering the preliminary examination, it would really raise it to a higher position.

Mr. MARSHALL said that if it was passed it would completely overturn a resolution of the Executive Committee so late as March last, by which it was resolved that all the subjects required at any preliminary examination must be passed at one examination.

Dr. STRUTHERS, in reply, said he was very much surprised to hear that he was lowering the examination, for his idea was that it was rather the opposite. If there was anything in Scotland in which it was superior to England, it was in general education. They had no difficulty at all in their preliminary education.

The resolution was then put to the Council, and carried by ten votes to eight.

The Council then resumed, and the following report was brought up:—

"That the following resolutions, passed by the Council in Committee with regard to preliminary examination of medical students, be adopted:—That the subjects now required for the Preliminary Examination, as set forth in the Regulations of the Council, be modified so as to stand as follows: No person shall be allowed to be registered as a medical student unless he shall have previously passed a preliminary examination in the subjects of general education as specified in the following list: (1) English language, including grammar and composition; (2) Latin, including grammar, translation from specified authors, and translation of easy passages not taken from such authors; (3) elements of mathematics, comprising (*a*) arithmetic, including vulgar and decimal fractions; (*b*) algebra, including simple equations; (*c*) geometry, including the first book of Euclid, with easy questions on the subject matter of the same; (4) elementary mechanics of solids and fluids, comprising the elements of statics, dynamics, and hydrostatics [1]; (5) One of the following optional subjects: (*a*) Greek, (*b*) French, (*c*) German, (*d*) Italian, (*e*) any other modern language, (*f*) logic, (*g*) Botany, (*h*) zoology, (*i*) elementary chemistry."

Paragraph 1 having been agreed to,

Dr. HAUGHTON moved the omission of the footnote by which the Council presumed to teach the universities how to examine.

The question being put to the Council, Dr. Haughton's motion was agreed to, and the footnote was struck out.

On Paragraph 2,

Dr. LYONS moved that Greek be included. He did not

"[1] The General Medical Council will not consider any examination in English language sufficient that does not fully test the ability of the candidate:—(1) To write sentences in correct English on a given theme, attention being paid to spelling and punctuation as well as to composition; (2) to write correctly from dictation; (3) to explain the grammatical construction of sentences; (4) to point out the grammatical errors in sentences ungrammatically composed, and to explain their nature; and (5) to give the derivation and definition of English words in common use."

"[2] This subject may be passed apart from other subjects, at an examination conducted by any one of the recognised examining bodies."

Digitized by Google

desire to reopen the discussion, but merely to move it *pro forma* in order that it might be on record.

Dr. BANKS seconded the motion.

The motion was negatived.

The report having been adopted by the Council, Dr. STRUTHERS' motion, "That the subjects of the Preliminary Examination for medical students be allowed to be passed at one or more examinations," which had been carried in committee, was put to the Council and carried.

Dr. HUMPHRY said the whole tenour of the efforts of the Council had been that the examinations in preliminary education should be conducted as far as possible by the universities, and he thought it would be wise therefore on the part of the Council to carry any resolution which would distinctly hinder the acceptance of the preliminary examination at one of their great universities. He thought that the universities should be left as far as possible free to conduct those examinations, as to which they really must be better judges than members of the Council, and more especially as it was desired that in their early examinations medical students should conform as far as possible to the general mass of students preparing to enter other professions. When the College of Surgeons and the College of Physicians in loyalty to the Council gave up their preliminary examination, it was in the hope that the examination would be mainly conducted by the universities, but their apprehension also was that it might fall into hands no better than their own. He thought under all the circumstances it behoved the Council to be extremely careful how they in any way interfered with the examinations conducted by the great universities. He spoke mainly in reference to the position of Trinity College, Dublin, and was it desirable that they should increase the difficulty of their students passing the higher examinations of that university or that they should throw its students upon other examinations? He therefore proposed that the following be added to their resolutions:—"That the examinations in general education conducted by the universities will be accepted as heretofore, but if in any of those examinations in which the standard in mathematics is higher than in the examination here proposed, and in which the subject of preliminary mechanics is not included, a knowledge of that subject will be required at a subsequent examination." Thus in Trinity College, Dublin, where the men passed a considerably higher preliminary examination altogether in mechanics, they should allow them to pass their mechanics at a subsequent examination.

Dr. BANKS seconded the motion.

Mr. MACNAMARA said the Council were doing a most serious injustice to the University of Dublin by insisting on the resolution that mechanics must be passed before registration. They were imposing a regulation which if complied with would mean giving up a year's education in mechanics for a simple trifling examination at the commencement of the student's career. The result would be that the Council would stand in the position of refusing access to their student's register to Dr. Haughton's pupils because he gave them a better education in mechanics than the Council required.

Mr. SIMON dissented from the principle of Dr. Humphry's motion. He said the Council had deliberately decided that it would require elementary mechanics to be preliminary to medical education, and he believed that the Council had never given a vote more deliberately. He was prepared to admit that there might be one or two exceptional cases, but they must be very carefully guarded and must not trench on the principle that four years was required for medical education. Of course, if there was an institution which had a curriculum of five or six years, and it happened that there was a certain quantity of intermingling of mechanics and, perhaps, anatomy in the earlier of those years, the Council would not wish to push its regulations pedantically against such students, but the principle must be maintained that they required to be satisfied that there were four years of medical study exclusive of any of the preliminary subjects. His own impression was that they had better not move further in the matter at present. Let them take time to consider it and consult, if necessary, with the Colleges, and make exceptions that should just cover right cases and no more.

Dr. STRUTHERS said he would never be a party to deliberately opening a back door for the convenience of certain universities. Before the proposal was carried into effect a year must elapse, during which Trinity College would have time to consider what it should do, and no doubt they would be able to appoint examiners for the elementary mechanics' examination.

Dr. HAUGHTON said Trinity College would not alter its plans in a hurry, and he was quite sure would not do so in order to suit the convenience of the Council. There were no penal consequences attached to the regulations of the Council, and Trinity College certainly would not come down from a higher platform in order to take up a lower one.

Dr. HUMPHRY said they had been reminded that the Council was not making "laws," but only "recommendations," and what he wished was that they should not run into opposition to the great universities, because, if so, their recommendations would indeed cease to be law. At present those bodies had striven to bring themselves into accord with the regulations of the Council, and he knew what serious deliberations had been necessary at Cambridge in order to do this as far as they could. There was nothing so much to be desired, in order to promote the high education and gentlemanly tone of members of their profession, as that they should associate themselves with those great bodies which gave a truly liberal education. He hoped, therefore, that the Council would accept the resolution.

Mr. MARSHALL thought the question ought not to be decided in that way. It was quite clear the Council would not be unanimous. He did not see any great harm in making a communication to the different bodies of the changes already proposed by the Council without going into the mode in which they would affect any particular institution. No harm would be done by a little delay, and then the Council might ascertain what the bodies themselves had to say about those important changes.

The resolution was then put to the Council and lost, six voting for it and nine against.

Mr. MARSHALL then moved, "That the General Council's amended regulations for the preliminary examination of medical students be communicated to the examining bodies whose examinations are recognised by the Council; that their attention be drawn to the changes that had been made; that they be informed that these amended regulations will not come into force until October 1st, 1885; and that on and after that date no person will be allowed to be registered as a medical student unless he shall have previously passed a preliminary examination in the subjects of general education as specified in the following list," &c.

The resolution was seconded by Dr. STORRAR and agreed to.

With the consent of the mover and seconder, Dr. Struthers and Dr. Pettigrew, the following motion was referred to the consideration of the executive committee, "That the junior local examination of the University of Aberdeen, and the junior local examination of the University of Glasgow, be added to the list of preliminary examinations recognised by the Council; the certificates to include all the subjects required by the Council."

Owing to the evident desire of the Council to bring the business to a conclusion on that day,

Dr. HAUGHTON said that after a conversation with Sir H. Pitman he had decided to ask the Council for permission to withdraw two motions of which he had given notice, believing that the best place in which he could express his views upon them was in the lobbies of the Houses of Parliament. The motions were as follow:—1. "That, in the event of a conjoint scheme or schemes of curriculum and examination being adopted, it is not desirable to include in such schemes any university that can prove its curriculum and examinations to be distinctly in advance of the curriculum and examination contemplated in such scheme or schemes." 2. "That the Medical Act (1858) should be amended by requiring a degree or licence in each of the three subjects, medicine, surgery, and midwifery, to be produced to the Medical Registrar previous to the candidate's name being placed on the Medical Register."

Dr. QUAIN said that in a previous debate he had referred to a return showing the percentage of the licentiates of the College of Physicians who held the diploma of the membership of the Royal College of Surgeons. He then stated that "93 per cent. of the licentiates of the College of Physicians also got the qualification of the College of Surgeons voluntarily; but what was more strange was that 30 per cent. of them got the licence of the Apothecaries' Society." That statement was founded on an old return, but on examining the Medical Register of the last two years it was found that out of 160 licentiates of the College of Physicians, 134 held the M.R.C.S.E., and twenty-two the L.S.A.Lond.

MEDICAL LEGISLATION.

The following motion had been placed on the programme of the Council by Dr. LYONS:—

Digitized by Google

"That the Council consider the following propositions: (*a*) That a one-portal system can only be worked on the basis of a minimum. A minimum must necessarily paralyse intellectual activity in teachers and learners, arrest all forms of healthy competition, impede the progress of medicine as a scientific pursuit, and degrade the medical service of the public and the State. (*b*) A well-regulated many-portal system admits of being worked on the principle of competition upwards. Such upward competition can be secured by energetic supervision and control on the part of the Medical Council, with the best results to the public and the State. (*c*) To secure effective supervision, inspection, and control over teaching and examination, more direct power must be entrusted to the Medical Council by Parliament. The relations of the Medical Council with respect to the medical authorities and the Privy Council require to be reversed; the General Medical Council to be in the position of a court of first instance, with right of appeal on the part of the medical authorities to the Privy Council. (*d*) It does not appear to be either possible or necessary to enforce the *bonâ-fide* triple qualification in medicine, surgery, and midwifery universally. But no person should be allowed to practise midwifery whose name is not on the Register as possessing a special qualification. It will vitiate the whole system of registration if, for personal or other considerations, rigidity of examination in midwifery be relaxed to enable A, B, or C to fulfil colourably the clauses of a statute which shall pretend to enforce uniform triple qualification. (*e*) It appears to be a natural right that a representative body like the Medical Council, now probably to be endowed with larger powers, should be elected by a more extended representation of the profession than at present. This enlarged representative privilege may perhaps be most safely entrusted to the members of the medical authorities, taking a limit of years in practice, possession of special degrees, or other qualifications, as limitations. (*f*) The right of appeal will in all probability be exercised henceforth, and as the questions of appeal will involve special expert knowledge, it seems but proper that special and expert knowledge should be represented on the Courts of Appeal."

Dr. LYONS said he desired to say a few words in explanation of his bringing forward these very important resolutions. It appeared to him that the time had almost come in the history of the Council when it would be proper for that body to give its consent to some such propositions as he had drawn up. He could not, however, be blind to the fact that the present time was inopportune for their discussion, at the close of a period of as close and continuous study on the part of members of the Council as he had ever been called upon to go through. He thought that notwithstanding the cloud that at present appeared on the political horizon, there was strong reasons for believing that next year medical legislation would come to the front. He believed that the public desired more specific information with regard to the views of the Council upon that legislation than it at present possessed. Members of Parliament said, "Why do not you and the Medical Council take this in hand—you who can deal with it so much better than we of the House of Commons alone can hope to deal with it?" Representing as it did every constituent in the medical profession, the Council could no doubt offer great assistance in the settlement of matters which must appear complicated to those outside. One important point to be considered was the power to be entrusted to the profession at large in regard to its regulation and government through a body like the Medical Council. They knew that public opinion had taken a particular direction in regard to a general system of representation, and there was no doubt good ground for demanding it. At the same time they might be guided with a direction that would give full and complete satisfaction to the profession without bringing in the somewhat disturbing element of universal suffrage. He was, if he might venture to say so, in favour of a large extension within proper limits within the profession, and within the bodies corporate forming the profession, of the area of the suffrage by which men could properly be returned to the various bodies represented in that Central Council. With reference to medical legislation, it would be a great advantage if the Council were to consider the lines upon which a measure might be drawn up; for even if it should not run exactly on the lines on which the Legislature intended to work, both schemes might be considered by a select committee, and a Bill drawn which would include the best ideas emanating from both sides. Having made this general statement of the objects he had in view, he would for the present, considering the lateness of the session, withdraw his propositions, reserving to himself the right to reintroduce them at a future sitting of the Council.

The propositions were then, by leave of the Council, withdrawn.

The following letter to the President from the Master of the Society of Apothecaries in London, on the subject of the exclusion of that Society from the Conjoint Scheme, was read:—

[COPY.]

Apothecaries' Hall, Oct. 15th, 1884.

DEAR SIR HENRY ACLAND,—I beg leave to acknowledge the receipt of the several reports of the meetings of the General Medical Council during the past week, which have been forwarded to me as Master of the Society of Apothecaries. Permit me to point out to you a serious discrepancy in these reports, which materially endangers the interests of the Society. It will be in your recollection that when a Conjoint Board for England was originally proposed (see "G.M.C. Revision," June, 1877), the Society of Apothecaries could not then join in the movement with the two Royal Colleges. In order to do so we were compelled to make important sacrifices and surrender certain powers and privileges. The basis of that scheme, approved and adopted by the General Medical Council in February, 1879, consisted in giving a majority of examiners in medicine to the Royal College of Physicians; the Society was accredited with a majority of examiners in chemistry, materia medica, &c.; whilst the departments of surgery, anatomy, &c., were to be undertaken by the Royal College of Surgeons, since the Apothecaries Act does not confer the power of examining in surgery for our licence. Final arrangements were further made for carrying out the three portions of the Conjoint Board in its examinations: the first was to take place at the Apothecaries' Hall, the second at the College of Surgeons, and the third at the College of Physicians. From this scheme the Royal College of Surgeons withdrew some time after the above arrangements. In your address on Oct. 7th you suggest the adoption of three short clauses legally binding on the examining boards, in the first of which the Council shall not admit to the Medical Register any person who has not passed an examination satisfactory to the Council in medicine, surgery, and midwifery. The Society of Apothecaries adopted the scheme of 1878–9 upon these very grounds, and which the General Medical Council approved and sanctioned at that period. But now it appears that the Council have negatived their four resolutions in rejecting the amendments marked A, B, C, and D to Sir H. Pitman's motion of Oct. 9th, 1884, by which (B and C amendments specially) the Society of Apothecaries is refused the privilege of co-operating with the above-named Colleges, though the General Medical Council had previously agreed to adopt the scheme above referred to. In deference to the judgment of the General Medical Council, it appears that two errors are now committed: one of injustice in allowing the two Colleges to combine at all after the decisions of 1878–9; the second is a still greater injustice, in excluding the Society of Apothecaries, who were the parties most interested in that scheme, and who had made the greatest sacrifices in furthering the views of the General Medical Council in their Recommendations. I wish to press upon the attention of the General Medical Council that the Society is still willing to recur to the original project as laid down by the Committee of Reference in their report of the co-operating medical authorities, and approved by the General Medical Council, February 1879, Parts 1, 2, and 3.—I remain, dear Sir H. Acland, yours truly,

GEO. CORFE.

Sir H. ACLAND, President of the General Medical Council.

A proposition that the letter be placed on the minutes was negatived.

Dr. LYONS proposed: "That a committee be appointed to consider the question of a new, more wholesome, and more suitable place of meeting for this Council, whether by renting some more suitable building, or by the erection of a new structure; and that the said committee be requested to report to the Council at its next meeting."

Dr. WATSON seconded the proposition, which was agreed to, and a committee was appointed comprising Dr. Lyons, Sir Henry Pitman, Dr. Quain, Mr. Marshall, and Dr. Storrar.

This concluded the business, and after a few remarks from the President as to the time of their next meeting, the session terminated.

New Inventions.

GLYCERINE PAD PESSARY.

THE pessary here depicted is identical in construction with that invented by Dr. Greenhalgh, and called the "air pad pessary." Pessaries inflated with either air, water, or padded with moc-main or other substances, after a short period invariably become useless, as air escapes,

water evaporates, and padding becomes hard. This invention is intended to obviate these defects; the padded end is filled with glycerine, which always remains soft, and yet offers sufficient resistance to render the instrument effective. The pessaries are made by Messrs. Arnold and Sons of West Smithfield.

THE LANCET.

LONDON: SATURDAY, OCTOBER 25, 1884.

THE *magnum opus* of the Council, at its late meeting, was the discussion on Preliminary Education. It was commenced by Sir HENRY PITMAN, who soon perceived the questionable nature of the work, and evidently wished to recede from it. But the Council kept him to his resolution, and spent days over the subject. The chief objects were, as Dr. HUMPHRY put it, to limit the area of subjects in the Preliminary Examinations and to raise the quality of the examination. The chief results were to exclude English history and modern geography from the examination. The English language itself as a special subject of examination, as it is now, had a narrow escape, even Dr. HUMPHRY and Mr. SIMON proposing to ascertain the candidate's knowledge of English merely indirectly, from his answers to questions. But the patriotism of all the nationalities saved the Council from this discreditable result. A thoroughly sound examination in English would of itself be no mean Preliminary Examination, and the proposal to omit it was certainly a new anomaly in this most anomalous body.

One marked feature of the meeting was the disposition to recognise the Branch Councils more than has been hitherto the practice, and to give them work to do. This disposition found marked expression in a motion of Mr. SIMON'S, pledging the Council at its next meeting to reconsider its Recommendations on the subject of the age for licence to practise and of professional education and examination, and requesting the Branch Councils in the meantime to review these Recommendations, to confer with the licensing bodies in regard to them, and to communicate to the President any suggestions they may have to make for their amendment. It is hoped in this way to bring the question before the General Council in a state much more fit for discussion, and to avoid waste of time. Apart from experience of the working of the Council, one would willingly join in such a hope. But in the light of our knowledge of the Council and its ways we can hope for little from such an attempt to give the Branch Councils serious work to do. They will be likely to waste much time and money over their own parochial discussions, and to come to the General Council only the more determined to assert their national peculiarities, and to base on them objections to regulations intended to promote fairly equal arrangements and examinations in each division of the kingdom. Sir HENRY ACLAND, indeed, magnified the motion. He had little doubt that if the motion were carried, it would prove to be one of the most important acts that had ever taken place since the formation of the Council. It would carry out the spirit of one of the most important recommendations of the Royal Commission—viz., that a portion of the work of the Council should be done by the Branch Councils. Sir HENRY is a charitable man. He has that happy suavity of mind that can see the best of all arrangements and forget the worst. We shall not try to discourage him or to undeceive him. We will only remind him that it is one thing to take the Recommendations of the Royal Commission in their entirety, or even in the order of their importance, and quite another to pick and choose: to take that which is agreeable to the whims of the nationalities, and to refuse that which is meant to make them work together for the good of the whole empire. Sir HENRY ACLAND is by far the most responsible man in the Council. He is so by reason of the office he holds, and to which he has been no less than three times elected. He is so still further as being one of the few members of the Council who has been such from the beginning, and who, in spite of his charitable and optimistic nature, must be convinced that the Council works badly, and never will work well. He is so, finally, as holding a position of considerable independence in the profession and in the Council. He is no doubt high in the Councils of the College of Physicians, but he is mainly identified with the ancient University of Oxford, and as such ought to look at questions of medical education from an independent point of view. There is no man who has greater opportunities, and if he liked to use them, greater powers of convincing men of different schools and nationalities of the undignified position in which they have placed themselves and the Council by their opposition to the Government views of reform. By such a use of his opportunities and his powers he would do a service to medical education and the medical profession which cannot be over-estimated. But he must cultivate a little more of the *fortiter in re* if he is to achieve this service, and to leave his mark on the medical profession of the future. He cannot but have been pained to learn from the letter of the Vice-Chancellor of his own University, from Dr. HAUGHTON, and others, how lightly the Recommendations of the Council are esteemed by the great universities. He must have been similarly affected when he heard from Sir HENRY PITMAN—after all the labour of the Council in formulating Rules for preliminary examination in mechanics three years ago—that in the past year of 274 candidates examined by the College of Preceptors only four passed in Mechanics. The President must be under no delusions. He must not imagine that the reference of a subject to Branch Councils will make up for the loss of the Medical Bill. The "wicked will do wickedly," and the Medical Council will act according to its nature—incompletely, inharmoniously, and ineffectually.

Dr. LYONS, indeed, still dreams of medical legislation, or rather of an ambitious minister being still desirous to succeed where others have failed. This is very likely. But Dr. LYONS is a very sanguine man. He must think with exaggeration of the patience of ministers if he imagines much of it can survive the notice of 185 amendments in a Medical Bill, including one of his own, for achieving no less a feat than an alteration of the constitution of the House of Lords. No; only one of two or three things can make medical legislation possible. The chances of an election that might remove men from the House who have so terribly wrecked the train of medical reform; a radical alteration in the rules of the House, fitting it to work instead of to talk; or the influence of a man like Sir HENRY ACLAND, who could be suspected of no personal or official purpose in trying to convince medical bodies and public men how

Digitized by Google

lamentable is the powerlessness of the Medical Council, and the sentiment of disrespect for it entertained in the profession.

IN his address at the Medical Society of London, which we print in our columns to-day, Sir JOSEPH LISTER deals in his own accurate and scientific way with the use of corrosive sublimate as an antiseptic surgical dressing. To learn that this is the "newest" antiseptic agent may perhaps suggest the reflection that "there is nothing new under the sun," for the use of corrosive sublimate as a dressing dates far back. Quite recently, however, it has been introduced into practice as a good substitute for carbolic acid, iodoform, and the other powerful antiseptic agents with which we are familiar. It has been largely used on the Continent, and some of our own countrymen have employed it for some time with, we believe, considerable success. Dr. PAUL BRUNS has just published in LANGENBECK'S *Archives* (Bd. xxxi. H. 1) a short paper containing his results of the use of this antiseptic agent for a period of fifteen months. He has employed it in the form of a lotion (1 in 1000) for cleansing and irrigation, and has used for his dressing "wood-wool," or a mixture of "wood-wool" and cotton-wool impregnated with a one-half per cent. solution. He has found it to afford complete protection against erysipelas and other wound diseases, and states that he has obtained the primary healing of wounds with greater frequency by this than with other forms of antiseptic dressing. Of a total of 557 cases of operation and accidental wounds thus treated only 10, or 1·7 per cent., died; the causes of death in these cases were diphtheria (2), croupous pneumonia (2), miliary tuberculosis (2), ileus (2), amyloid degeneration (1), and shock (1). Much of the success thus recorded is to be attributed to the fact that the dressing was a "dry" dressing, and was allowed to remain unchanged for periods varying from one to three weeks, and that equable elastic compression of the parts was maintained all the time. It is an error to suppose that the nature of the antiseptic agent used can exert any direct influence over the primary healing of the wound, provided only that it be not so severe an irritant as to excite inflammation. Primary healing is a natural process, governed by laws of which we know at least as much as this. The antiseptic prevents the development of organisms which would interfere with primary healing and expose the patient to the danger of systemic infection; but provided the antiseptic be not itself an irritant, and the other essential conditions be complied with—such as rest, coaptation of surfaces, fixation, absence of tension,—primary union takes place quite independently of the nature of the particular antiseptic agent employed.

Sir JOSEPH LISTER'S experiments detailed in his address threw a flood of light upon the practical application of the sublimate. It is obvious that this substance offers great advantages as an antiseptic agent. It is cheap, non-volatile, very readily soluble, and extremely potent as a germicide. But Sir JOSEPH saw that its practical value must largely depend upon the strength in which it can be used without causing local irritation or general poisoning, and also upon the effects produced by an admixture with the albuminous fluids of the body. It is well known that albumen yields with corrosive sublimate an insoluble coagulum of a so-called albuminate of mercury, and there appeared some ground for the fear that serum or blood soaking into a sublimate dressing might destroy its antiseptic properties, and destroy its power of protecting against decomposition. The large proportion of albumen in blood and wound-discharges, and the necessary dilution of any sublimate dressing, made this additionally probable. By experiments, however, he demonstrated that this inert coagulum of albuminate of mercury is soluble in excess of albumen, and that this new solution, containing possibly a double albuminate of mercury, retains all the antiseptic virtues of the original sublimate solution, whilst its irritant properties are greatly mitigated. For the details of the conclusive experiments by which Sir JOSEPH has proved these points we must refer to the report of his address. The fact that the inert coagulum of "albuminate of mercury" is soluble in excess of albumen is by no means new. The caution not to give an excess of albumen in cases of corrosive sublimate poisoning lest the coagulum at first formed should be redissolved is insisted on by teachers of toxicology; and SQUIRE, in his Companion to the Pharmacopœia published in 1877, states that the white of one egg is equivalent to four grains of the sublimate, and that more than that proportionate amount must not be taken. By using, not a simple solution of sublimate, but a solution of this double albuminate or sero-sublimate, Sir JOSEPH LISTER obtained a cheap, fixed, and very powerful antiseptic, which is totally devoid of poisonous or irritating properties in any strength in which it may be necessary to employ it. In this, then, we appear to have an agent possessing for surgical purposes nearly all the properties of a perfect antiseptic. Professor LISTER has employed a gauze saturated with 1 in 100 of this double albuminate, and he has found it as trustworthy as the best carbolic gauze. Its use in some measure simplifies an antiseptic dressing, for it renders unnecessary the protective and the impermeable mackintosh cloth. The sublimate solution cannot be employed for cleansing instruments, and is less penetrating than carbolic lotion, which is therefore superior to the sublimate for cleansing the skin around a wound. It is efficient when used to irrigate a wound, and can be employed as a spray, but its action on instruments renders it for this purpose far inferior to carbolic acid.

Sir JOSEPH LISTER did not confine himself to a consideration of the surgical uses of corrosive sublimate, but somewhat incidentally mentioned certain other important facts. He alluded again to the circumstance that, although iodoform is a very powerful preventive of putrefaction, it is not a safeguard against erysipelas, that it is not a potent germicide, and delays but for a short time the lactic fermentation of milk or the ammoniacal fermentation of urine. He stated that he had met with imperfect results while using eucalyptus gauze, and in one case had to record a death from septicæmia. This was due, not to the failure of eucalyptus to prevent the development of septic organisms, but to the fact that the gauze had been carelessly prepared, and the volatile antiseptic had been allowed to evaporate. This is a source of danger in the case of all volatile antiseptics that requires to be kept constantly in view, and unquestionably accounts for many failures to obtain the usual results of aseptic surgery. One of the most remarkable facts presented by Sir JOSEPH LISTER was in reference to a blood-clot which he exhibited

Digitized by Google

to the meeting. The blood, which was from a horse, had been drawn into a glass vessel rendered aseptic by corrosive sublimate; it coagulated in the usual way, but even in an interval of several weeks not the least contraction of the clot had taken place. Sir JOSEPH had met with the same result in some cases where the blood had been drawn into vessels rendered aseptic by heat, and had suspected that it might be explained by some special physical change produced in the glass by heat. Without stating that the absence of living organisms was the cause of the non-contractility of the coagulum, Sir JOSEPH LISTER remarked that the fact pointed in that direction, and he was unable otherwise to explain it. The practical interest of this fact is immense, and we hope further light will be thrown upon it.

A MAJORITY of the members of the General Medical Council, after two days' discussion, has, for various and even contradictory reasons, sanctioned the proposal of the Royal College of Physicians of London and of the Royal College of Surgeons of England to co-operate in order to form a common joint examining board for granting their respective diplomas in medicine and surgery. Sir HENRY PITMAN, representative of the College of Physicians, moved, and Mr. MARSHALL representative of the College of Surgeons, seconded, that the Council should give its sanction to this proposal. After several amendments had been proposed and negatived the original motion was put to the vote, when fourteen of the twenty-four members of the Council voted for its adoption, while the remaining ten did not vote. Though carried, the motion therefore received the direct and active approval of only a very small majority of the Council. Apart from the importance of the matter at issue, it is worth while to consider the character and constitution of this majority. There were the two representatives of the English Colleges; a gentleman who, though nominally representing another body, receives over £400 a year as a member of the Court of Examiners of the Royal College of Surgeons; and all the (five) representatives of the Scotch universities and corporations. In other words, at least eight of the fourteen members of the Council who voted in favour of the adoption of Sir HENRY PITMAN'S motion represent or are otherwise interested in institutions that are likely to be more or less affected by the change. By combining with the College of Physicians the College of Surgeons doubtless hopes, among other things, to do something to wipe out the stigma and reproach of having for eighty-four years sold a qualification for practice which implies no satisfactory guarantee of proficiency in medicine and midwifery; while the College of Physicians sees an easy way of greatly increasing its income if every applicant for the Surgeon's diploma can, *nolens volens*, be forced to pay its fee of fifteen guineas for examination in medicine and midwifery. On the other hand, the representatives of the Scotch universities and corporations, with characteristic and perhaps truer foresight, anticipate that English students will not permanently submit to the extortion of paying thirty-six guineas for a so-called "double" qualification, which may be obtained in Scotland at considerably less cost in labour, thought, and money. They probably also foresee that students may likewise discover the advantages of pursuing their professional studies where they will be examined, and of receiving their instruction at the hands of those who will eventually examine them. Time alone will prove which is the truer forecast, that of the English colleges or that of the Scotch examining bodies. Meanwhile, the Council of the College of Surgeons, with remarkable promptitude and dexterity, has taken steps to give immediate effect to the combination. In its zeal it has even resolved that the regulations shall be retrospective. The sanction of the General Medical Council was formally given on the 9th inst., and exactly a week later the Council of the College of Surgeons resolved that the Regulations should have force from the 1st inst. Whatever of good there may be in the combination, the plan of carrying it out is faulty, and, above all, the fee is impolitic, extortionate, and unjust.

THERE are few diseases which in their origin, mode of development, and course better harmonise with the doctrine of a dependence upon pathogenic micro-organisms than diphtheria. Its contagiousness, the character of its local manifestations, the manner of extension of the false membrane, and the varying intensity of the general symptoms, apparently due to the absorption of a more or less virulent poison—these and other clinical facts of the disease can admit of but little explanation, except that afforded by the germ theory. Hence it is that the attention of pathologists was early directed to diphtheria; and yet in spite of many elaborate researches the precise nature of the diphtheritic virus is still a matter of doubt. Of those who have studied the question from the pathological and experimental side, the majority declare in favour of a specific micrococcus; which is to be found not only embedded in the membranous deposit, but in the lymphatic spaces beneath the mucous membrane, in the blood, and in internal organs. Amongst those who have declared in this sense are OERTEL, EBERTH, and KLEBS, and the most recent advocates are Drs. H. C. WOOD and H. F. FORMAD of Philadelphia. Their report, which is intended as an Appendix to the Report of the National Board of Health, 1882, is issued this year in a separate form, but we regret to add that the character of the letterpress, and of the illustrative engravings, is wholly unworthy of so important a document. In spite of these very obvious blemishes, it is plain that their work is the outcome of much painstaking research, microscopical and experimental, although it is not easy to extract therefrom any very definite and precise conclusions. This, however, may be said: they find invariably in the membranous exudations of diphtheria masses of micrococci, which are indistinguishable from similar organisms found in the buccal and pharyngeal mucous membrane in other conditions. In many cases, especially those which occur in epidemics, rather than in sporadic cases, similar organisms were detected in the blood and various internal organs. They are to be found in epithelia and in the substance of white blood-corpuscles. Cultivation experiments prove that they multiply best at a temperature between 37° and 40° C., and they do not appear to require a large supply of oxygen to maintain them. Inoculation in rabbits produced varying effects, according as the original source of the virus was from a malignant or a mild case, in the former case a fatal result being rapidly brought about, whilst in the latter often but slight effects followed. In fact, the report tends to show

Digitized by Google

that the diphtheria micrococcus is identical with a non-pathogenic organism, and that in its history we have an instance of that assumption of virulent properties in particular conditions, which Dr. KLEIN has proved to be of such rare occurrence. And as to the membranous inflammation that characterises diphtheria, that is not the special result of the virus, but only an index of intense inflammatory change.

LOEFFLER, in his lengthy memoir contributed to the second volume of the Reports of the German Imperial Board of Health, recounts an extensive experimental inquiry upon diphtheria in animals and man. He, too, confirms the fact that micrococci prevail in the diphtheritic membrane, mingled with other forms of bacterial life which find a suitable nidus in the necrosed and decomposing tissue. But he lays more stress, from the etiological point of view, upon the presence of a bacillus the detection of which was first made by KLEBS—an organism that invariably occurs in association with the micrococci, but presenting far more than those the attributes of a specific virus. Thus, whereas inoculation experiments with cultures of the micrococcus were for the most part negative, cultures of the bacilli proved very virulent in action, at least on guinea-pigs. LOEFFLER's research upon diphtheria in pigeons and calves pointed to the probability of the disease in animals being due to a variety of bacillus different from that which excites it in man. But in every case the diphtheritic process would seem to be at first entirely local, the constitutional effects of the disease being due to a poison developed by the specific organism at the original seat of attack.

EMMERICH (*Deutsch. Med. Woch.*, No. 38) has arrived at different results from any hitherto recorded, the material for his research being furnished by eight severe cases of human diphtheria and six of the same disease in pigeons, the latter obtained from a Munich fancier who last spring lost seventy young birds from the disease. The micro-organism which EMMERICH claims to be distinctive, which occurred in the diphtheritic lesions both of the pigeon and of man, is neither a coccus nor a bacillus, but a short, thick bacterium, which in gelatine cultures forms a pellucid greyish colour, assuming a whiter appearance as it develops, and not liquefying the gelatine. Upon potato it forms a thick yellowish-white layer, thriving luxuriantly; but in blood serum this bacterium does not grow well. In form, size, and mode of growth the diphtherial bacterium of man is identical with that of the pigeon. Moreover, inoculations were readily and successfully practised with pure cultures of this organism. Pigeons, rabbits, and mice were subjected to such experiment. A culture obtained from a diphtheritic membrane in a child was applied to the tracheal mucous membrane of a rabbit. The animal died in three days, exhibiting a dirty yellow infiltration of the tracheal mucosa, which was also coated with a coherent croupal membrane. Similar effects followed inoculation in the pigeon. These bacteria were also obtained from the blood, liver, spleen, and kidneys, and cultures of them derived from those regions were used for inoculation with like results to those directly made from the diphtheritic membrane. The symptoms produced in the pigeon by inoculation from human diphtheritic membrane were identical with those occurring in the spontaneous disease. The bacteria were met with in the blood and internal organs, especially the kidneys, of all the animals so inoculated, and the characteristic colonies obtained in cultures from these. Frequently the number of bacteria was too small to be detected microscopically, but their presence was ascertained on cultivation.

This cursory sketch will suffice to show that amongst the bacteriologists themselves very great differences of opinion prevail as to the morphology of the diphtherial fungus, and the list might be greatly extended if the older notions of more highly developed fungi being specific to the disease were included. But there is also lacking unanimity upon the mode of action of the parasite—e.g., the necessity of its being conveyed bodily into the blood, or whether a poison is developed at the locality of inoculation, which being absorbed produces the general malady. On either view, the doctrine that diphtheria is at first a local disease, and that the constitutional symptoms depend upon general infection from this local lesion, is the one to which all investigations tend, and this most harmonises with our clinical knowledge. EMMERICH thinks that researches such as his should incite us to redouble our efforts to ascertain the conditions under which the diphtherial germ can exist apart from the body; and in this regard special attention must be directed to the condition of dwellings. He reminds us of the explanation he found of the recurrence of outbreaks of pneumonia in Arnberg prison, and in the discovery of the pneumonia micrococcus between the floors of the building. Diphtheria, he thinks, is essentially a house-disease, prevailing in those seasons in which dwellings are most likely to be overcrowded. Measures of prophylaxis based upon bacteriology must, however, lie in the future, and most of us will be content with the enforcement of general hygienic laws without reference to the supposed habits of a special form of micro-organism. The actual treatment of the disease by the early and efficient destruction of the local manifestations, the best means of doing this, and the methods of combating the severe constitutional depression which marks the further progress of the malady, are questions which have always engaged the attention of physicians since diphtheria came to be recognised as a distinct entity.

THE time is rapidly approaching, if, indeed, it has not arrived, when some serious attempt must be made, in the interests of public morality not less than of personal health and happiness, to place the question of insanity in relation to suicide on an intelligible footing. It will not be denied, and it can scarcely be doubted, that as matters now stand there is, and always must be, a sentimental impulse in the mind of every juryman, of every coroner, of every medical witness, to give the fullest benefit of the doubt, whenever the least colourable reason for doubt or question can be discovered, as to the alternative hypotheses of culpable self-murder and irresponsible suicide. It is only natural that there should be this desire, and it will always exist, so long at least as grievous penalties are attached to the crime of self-murder—penalties which are now felt to be visited on the bereaved friends rather than on the offender. In the old days, when burial according to the rites of a Church was held to ameliorate the final or intermediate state of the departed, the penalty of burial with maimed

Digitized by Google

rites, or without any religious service at all, was felt to be one of extreme severity; and probably the dread of such treatment after death may have acted as a deterrent. Those days have passed, and popular feeling is changed too, whether for better or worse is not the question before us. The fact we have now to face is that, particularly since the insurance companies generally have made assigned policies indisputable, there has been nothing beyond a vague dread of undefined contingencies to influence for good the mind of the intending suicide. It is almost certain that, except in the most flagrant case of suicide by a murderer, the verdict returned will be one in which "temporary insanity" is hypothecated to clear the charge and wipe out a possible blot on the family escutcheon. Our present contention is that it is important that there should be some rational endeavour to make the distinction between insanity and life-weariness apparent.

Are we about to allege that a coroner's court and jury constitute a tribunal before which the issue raised in hese cases can be intelligently or justly tried? Most certainly not. Nothing could well be more at variance with our view. We think such an issue as this can only be decided by a medical judgment, and even by that with great difficulty, when there is no trustworthy evidence as to the actual state of the mind of the deceased person shortly or immediately before death. It is not, we hold, except in rare instances, practicable to form any good inference as to the state of the mind from the manner of the death. Of course, if, as occasionally happens, the mode of self-murder is in itself conclusive evidence of insanity, that may be available as proof of the existence of mental unsoundness, but in ordinary cases of suicide by drowning, hanging, cutting the throat, or taking poison, this inference is impossible. Again, absence of apparent motive is valueless, because "the heart knoweth its own bitterness," and under the calmest exterior there may be hidden a hell of remorse or despair from which even the sane mind seeks to escape, at all hazards as to the future. Such conceits as that no sane man would kill himself unless he were in the immediate presence of the extremest personal suffering or ignominy, or that the mind must be unsound that refuses to believe in a future, are too puerile to call for serious discussion. It must be admitted, whether we like it or not, that "self-destruction" is a mode of exit from this world of worries and disappointments which men and women in perfect enjoyment of their senses have in all ages from time to time adopted. What or who, then, is to determine, in any particular instance, whether self-murder was committed with a sane or with an insane conscience and purpose? We are bound to confess that, except in the extremely rare cases to which reference has just been made as implying insanity by the mode of death selected or carried out, and even in these cases great care needs to be exercised, there is positively no evidence available, and no means of forming a judgment outside, or in addition to, the inference deducible from the story of the deceased person's life.

We are strongly of opinion that this life-story, so far as it can be ascertained, ought in every case to be submitted to a committee of experts, and that no coroner's court or jury should be empowered or permitted to adjudicate on the issue "sane or insane?" let the dependent consequences be what they may. There is no need to hurry a judgment. The exceptional verdict which carries with it the penalty of interment at uncanonical hours, in unconsecrated ground, and without religious ceremonial, is, as we have said, never returned except in cases of murder, as well as suicide, and when the circumstances are so clear that no doubt or question can afterwards arise. All other cases should, we repeat, be reserved, and the issue of sanity or insanity carefully worked out. The interests of society require that this or some other precise procedure should be adopted. Suicides are on the increase, and, setting aside all questions of retributive or deterrent penalties for the crime of self-murder, it is imprudent to brand the craven crime as an act of ignominious cowardice, which, indeed, it generally is. We do not believe in "temporary insanity" as a common cause of, or excuse for, self-slaughter. We believe the great majority of persons who die by their own hands do so with an intelligent consciousness of what they are doing. It is not their psychical, but their moral, condition which is at fault. They want to flee from the trials and troubles of life. They do not like to be disappointed and indigent; they "cannot bear" the loss of property or friends. They are unable to face the ignominy of some exposure, or they find consciousness unendurable on account of some secret poignant remorse. These are the *true* causes of suicide, and the self-murderer takes life in a state of excitement it may be, indeed is likely to be, but he is as sane for all practical purposes, and in a scientific sense, as those around him, who are perhaps equally tried, but more patient. We fully and clearly recognise that mind is brain-function, and we are not forgetful of the way in which the mental part of man's nature acts upon, and reacts from, his physical organism; but we are not materialistic enough, yet at least, to look upon the human organism, with its consciousness, as a mere machine or apparatus by means of which correlated, concordant, divergent, and antagonistic forces work out a mean mental result. Until we do, if ever we do, arrive at this finality of surrender of all that is noble or even worthy in man, we must insist that the laws and usages of the community should be so ordered as to provide and supply incentives to right conduct and self-control, and deterrents from wrong-doing and self-surrender to passion and impulse. The charity that makes coroners' juries return verdicts of "temporary insanity" covers a multitude of sins—sins that ought not to be committed, and cannot safely be condoned.

MR. J. NOAKE, Severn conservator, in a recent letter to *The Times* states that the fact that some sort of fish are well known to congregate at the mouths of sewers seems to imply that diluted sewage is attractive to these fish, either as an alterative in their diet or medicinally, and otherwise grateful to the piscine stomach. During the late summer salmon disease has entirely disappeared from the Severn, although, owing to the length and extreme heat of the season, the Severn was correspondingly low, and therefore must have been, in proportion to the small quantity of water, more than usually polluted.

A DEPARTMENT of hygiene and bacteriology has been opened in connexion with the chemical laboratory of Prof. Fresenius at Wiesbaden. Dr. F. Hueppe, who has done much work under Dr. Koch at Berlin, has been appointed to the charge of this department.

"Ne quid nimis."

"A DOCTOR'S HEROISM:" SAMUEL RABBETH, M.B. LOND.

ON Friday, the 10th inst., a child aged four years, in the Royal Free Hospital, Gray's-inn-road, suffering from diphtheria, was threatened with suffocation, and to avert this Dr. Samuel Rabbeth, the senior resident medical officer, performed the usual operation of tracheotomy. The obstruction of the breathing was not relieved by the operation, and to save the child from the immediate danger of death by asphyxia Dr. Rabbeth, without the slightest hesitation, and well aware of the nature of the disease and of the peril involved, sucked the tube and cleared it of the obstructing membrane. The child was saved for a time, but afterwards sank and died. On Monday, the 13th, Dr. Rabbeth felt ill and weary; on the 14th symptoms of sore-throat appeared; during the next day or two diphtheritic patches were seen on his fauces and palate, and he expectorated large flakes of false membrane; on the 18th he was much worse; on the 20th he became cyanosed, and in the evening, about 7.30, he expired in a paroxysm of dyspnœa, which had lasted from two to three minutes. Needless to say, everything that colleagues and friends could suggest was tried. Drs. Cockle and West attended him, and Dr. Sainsbury was with him continually during his illness. Dr. George Johnson saw him on Monday afternoon, but the symptoms gave no ground for hope. He had expelled a complete cast of the trachea and one bronchus in a single piece and his exhaustion was extreme. The immediate cause of death was probably due to the formation of a clot in the pulmonary vessels. Such is, in brief, the melancholy story of the death of one of our young doctors, and the startling character of the narrative has brought forth a eulogium from many of our contemporaries. Single-hearted devotion to duty demands such a eulogium, and we are glad to find that the world can occasionally recognise and praise a hero in our profession as well as in others. To us it seems braver for a surgeon or physician to risk his life for a patient with no claims on his self-sacrifice or gratitude than for an officer against all odds to endeavour to save his comrade from the foe, even though that comrade be only a private soldier. There are ties of comradeship on one hand, duty only on the other. Many doctors die silently and unknown in the faithful discharge of their duty; cases like this move the public sympathy and teach them some of the perils of the profession and the spirit in which doctors have been taught to deal with them. Dr. Samuel Rabbeth was the son of one of the most trusted officials in Messrs. Coutts' bank in the Strand, and was educated at King's College School. He entered in the Easter Term of 1869, being then twelve years old, and steadily worked his way up to the highest form in 1876. In 1877 he matriculated at the University of London, and on the 1st of October entered the Medical Department of King's College. He passed the preliminary scientific and 1st M.B. Examinations of the University, and in 1880 gained a prize in Clinical Surgery and certificates of honour in other subjects. In the next year, having taken a medical diploma, he was appointed Assistant House Physician to King's College Hospital, and in the following May became full House Physician. In 1883 he obtained the Scholarship and Gold Medal in Midwifery at the M.B. Examination of the University, and was elected an Associate of King's College. In April, 1884, he succeeded his friend and fellow-student, Mr. R. Brooks, as Senior Resident Officer at the Royal Free Hospital, so that he had only held the appointment for some six months. In conclusion, we may add that apart from rapid perception and great intelligence, Dr. Rabbeth was always remarkable for decisive action and able organisation. His unselfishness was as marked in his student career as in the noble act which caused his death. Invariably genial and cheerful in the company of his fellow-students, as able in games of skill as in the examination-room and by the bedside, courteous to his superior officers, beloved for his many kindnesses by patients, nurses, and junior pupils, everyone with whom he had come into contact is now regretting his death as a personal loss.

EXAMINATIONS FOR PROMOTION IN THE ARMY MEDICAL SERVICE.

WE regret to learn that a considerable amount of discontent has been called forth by the recent Army Circular on the subject of examinations previous to promotion in the Army Medical Service. We have always held that the abolition of the examination of surgeons in 1874 was a great mistake, and that, in the interests of the soldier, it was requisite that means should be taken to ascertain that the medical officer, after obtaining his commission, had continued his studies with a view to keeping up and increasing his professional knowledge. We do not think that any reasonable objection can be raised to the resumption of such examinations, and on this point we believe the discontent is confined to a very small body of officers. It is to the examination of surgeons-major before they can be selected for promotion to the grade of brigade surgeon that exception has been chiefly taken. It has been stated to be an insult to officers who have attained the rank and the age of the surgeons-major to call upon them to submit to an examination. We confess that we cannot look upon it in that light. Among the improvements which have been introduced into the department has been the selection of officers for the administrative ranks, instead of the old disastrous system of giving it by seniority, irrespective of all other considerations. But if a selection is to be made, it is not unnatural that the Director-General should desire to be satisfied that the officer to be selected is acquainted with the rules of the service and the nature of the duties which he will be called upon to perform. It has been stated by some of the non-contents that brigade surgeons are not administrative officers; but they are liable to be called on, in certain circumstances, to perform administrative duties; and it appears to us better that they should be required to prove their fitness at an early period of their service rather than when they are just approaching its close. With one exception the subjects stated in the circular as those with which he must prove himself acquainted are all administrative and sanitary, and are such as every administrative officer ought to know well. The one exception is—"Questions on operative surgery and practical medicine will also form part of this examination." We think it would be judicious if the Director-General were to expunge this paragraph. The officers will be required to prove their knowledge of these subjects before promotion to the rank of surgeon-major, and it appears unnecessary again to subject them to an examination upon them. There does not appear to be any greater insult in examining a surgeon-major on those points relating to special duties than there is in the College of Surgeons examining members before admitting them to the Fellowship. On one point the circular is not explicit: it does not state at what period of his career an officer may present himself for the examination. If he is permitted to do so shortly after attaining the rank of surgeon-major—that is, after twelve years' service—he will still be comparatively a young man. We think there is much to be said in favour of an examination, in the interests alike of the patients and the medical staff; but we would suggest that it should be taken at as early a period as may be convenient, and that it should be confined to administrative

Digitized by Google

duties and to the organisation and working of the department and its relation to the other branches of the service.

BLOOD-PRESSURE IN AORTIC DISEASE.

THAT the arterial pressure is not, as commonly supposed, diminished in aortic insufficiency is the outcome of a clinical and experimental research by MM. Potain and Franck, who related their results at the meeting of the French Association for the Advancement of Science. M. Potain said that although the sphygmograph appeared to show a diminution of the blood-pressure, it was really inadequate to do so, and he exhibited a series of tracings taken simultaneously from the same patient, which showed remarkable variations. The sphygmograph, whilst indicating the relation between the propelling power of the heart and the peripheral resistance, does not inform us of the absolute cardiac force. An instrument invented by Bach attempts to supply this defect; it consists of a rubber bag connected with a manometer by a tube of the same material, and it yields fairly accurate results. By its use M. Potain studied the blood-pressure in fifteen cases of aortic insufficiency, simple and complicated, and found that in the former group at any rate the pressure is equal to, or even higher than, the normal. In one case only was it lower, and that was complicated with phthisis, and had probably some myocardial change. When insufficiency is not pure the pressure may descend below the normal. From these results it is argued that the old idea referring all the symptoms of aortic regurgitation to a diminution in the blood-pressure should be abandoned; the usual dietetic restrictions may be modified, and digitalis should never be given, or only with much caution. M. Franck substantiated the clinical inferences by experiment, producing artificial lesions of the aortic valves in animals, with the effect of a marked increase in the energy of the cardiac contractions, and in the number of pulsations. In attempting to determine the conditions which should suffice to maintain the normal blood-pressure in aortic insufficiency, M. Franck found that it is necessary that the heart's force should be increased and the peripheral outflow be diminished—e.g., by narrowing of the peripheral vessels. These conditions are precisely those which take place in man in this disease. Moreover, the phenomena of the affection are just as well explained on the high-pressure theory as they are on that of low pressure.

OVERCROWDING RAILWAY CARRIAGES.

A SINGULAR defect in law was exposed by a decision given at Westminster Police-court a few days ago. A gentleman who had been subjected to a good deal of annoyance, and had even sustained some personal injury in an attempt to prevent the overcrowding of a railway carriage on the North Western line, applied for instruction as to the power of the law in such a case. He was informed that in consequence of some oversight in drawing up the Railway Bills, the Companies were in this regard not liable to legal correction. The subject would appear to have been treated as an affair between the railway officials and the passengers, to be settled in the readiest way, and uncontrolled save by varying inclination or by length of purse on one side or the other. It is not to be expected that any department of the public service would persist in quarrelling with those who support it on a mere point of convenience, but exceptional temptations may easily arise under pressure of business, and to meet them the generally good intentions of custom should be fortified by rule. In railway travelling many circumstances render this advisable. Apart from the innumerable lesser discomforts which arise from such a fault as overcrowding, real and sometimes serious danger may be thus occasioned. The ventilation of carriages is too apt to be either draughty or inadequate. How far it shall be satisfactory is more or less at the option of individual passengers. The difficulties connected with its management are necessarily much increased by the careless herding together of surplus occupants in the restricted space. One cannot tell, moreover, who his fellow-passenger is. Perhaps he has come from an infectious sick bed, or is unconsciously himself the seat of an incubating fever. The altogether inordinate packing of excursion trains again is a colossal error, difficult, perhaps, to obviate entirely and at once, but capable, under judicial regulation, of very great amelioration. On account of the frequent occurrence and the increasingly wide extension of this practice, the danger from accident and illness inherent in it, and the deserving need of the class whom it especially affects, it is to be hoped that legal powers may be obtained which shall stretch the present economy of railway companies to a measure consistent with safety and convenience.

MODERATE DRINKING.

THE Bishop of Exeter and others have been declaiming against moderate drinking. It is high time to define what moderate drinking is not. It is not drinking in public-houses; it is not drinking on the sly; it is not drinking early in the day; it is not drinking by itself at other than meal-times; it is not drinking to procure sleep or to relieve pain. All men, and especially all women, who do such things, are not moderate drinkers, and had better beware. A moderate drinker takes a very limited quantity once or at most twice a day, *with food*, such a quantity as does not make him stupid or even sleepy, such as leaves him cool and unexcited. The moderate drinker takes the lightest forms of alcohol, and takes even these with care. He knows the power of alcohol to produce disease, and is on the look out for any indication of harm or excess. We do not think it proved that such persons become drunkards. It is terrible, however, to see how soon a drunkard is made by *thoughtless* drinking, and how complete is his physical destruction often before he, or perhaps she, comes under medical notice. Jaundice, or dropsy, or albuminuria, or delirium tremens, may have been reached before friends, unwilling to admit what they fear, will send for the medical adviser and make a clean breast of it. Alongside all the teetotalism that exists there is still an appalling amount of tippling which does not distinctly intoxicate, but saturates the principal organs and destroys them more quickly than an occasional debauch. But, as we have said, this is not moderate drinking—it is mortal drinking.

DISTILLED WATER IN CALCULOUS DISORDERS

IT is now some years since Dr. Murray drew attention to the fact that the continued use of soft water brought about in many instances the disintegration of small renal calculi. Since then soft or rain water has been extensively employed, not only for the solution of calculi, but also for the relief of dyspepsia associated with persistent deposits of urates and oxalate of lime crystals. In the country, with opportunities for the storage of rain water, there is no difficulty in procuring a sufficient supply of soft water for the purpose, but in large towns considerable difficulty has been experienced in obtaining soft water in quantity and also sufficiently fresh to be palatable—the distilled water sent out by chemists in gallon jars, which is generally resorted to, being apt to become stale and acquire an unpleasant flavour by keeping. This difficulty has been met by supplying distilled water in an effervescing form by charging it, we believe, with carbonic acid gas. This renders the water brisk and palatable, without, as a rule, impairing its solvent action. Still there are some cases, notably those

Digitized by Google

attended with persistent deposits of oxalate of lime in the urine, in which the ingestion of large quantities of water charged with carbonic acid is not advisable, and it would be a distinct advantage if, in addition to distilled water rendered sparkling with carbonic acid, we could procure a water simply charged with compressed air; whilst a water so charged, but with an additional volume of oxygen introduced, would often be a distinct advantage. Independently of its use as a solvent, it must be remembered that distilled water is one of the best and simplest diuretics, and that in a pleasant and palatable form it could be employed with benefit in many of those cases of dyspepsia in which the urine is highly concentrated, and which Murchison considered to be the result of lithæmia.

MEDICAL SOCIETY OF LONDON.

THE first ordinary meeting of this Society was held on Monday last, Mr. Arthur E. Durham, F.R.S., President, in the chair. The event of the evening was a dissertation on Corrosive Sublimate as an Antiseptic Dressing, by Sir Joseph Lister, Bart. The meeting began with a brief address by the President, in which he commented on the satisfactory condition of the Society in every particular. The library was gradually getting into a state of order due to the exertions of the hon. librarian, Dr. W. H. Allchin, and already 2000 books on anatomical and physiological subjects were catalogued and placed on the shelves of the library. Reference was also made to the losses from death sustained by the Society. Sir Erasmus Wilson had been a benefactor of the Society, as he now was to be by his munificent bequest to the Royal College of Surgeons, to the medical profession, and to the world at large. A resolution proposing a vote of condolence with his widow was moved by the President in the following terms:—"The Fellows of the Medical Society of London beg to express the deep sorrow with which they heard of the death of Sir Erasmus Wilson, their former President, whose services to and whose interest in the Society they so highly appreciated, and to offer to Lady Wilson every expression of sincerest sympathy in her irreparable loss." The resolution was seconded by Mr. R. W. Parker, and unanimously passed. The loss of Drs. Henry Aldred, Kempthorne, and Benjamin Terry Hodge, Fellows of the Society, was also mentioned. The illness of Mr. John Gay was referred to with much regret. The congratulations of the Fellows of the Society were offered to Dr. Wiltshire on his reappearance amongst them. The annual volume was placed upon the table, and its early completion must be ascribed to the energy and industry of the hon. secretaries, Mr. Pearce Gould and Dr. Kingston Fowler. Sir Joseph Lister then read his paper, which will be found in full at page 723. Owing to the lateness of the hour, no discussion followed the reading of the address, which was highly applauded. Before the meeting began Newham's patent invalid bed-lift was exhibited.

THE STATE OF THE THAMES.

OUR contemporary, the *Metropolitan*, attacks us for ascribing the present dangerous and disgraceful state of the Thames to the Metropolitan Board of Works. We can only reply by reiterating our statements. The present system was devised, and the present outfalls were selected, by the engineers of the Board; and the Board, availing itself of the almost unlimited powers conferred upon it by the Act of 1858, carried out the works in spite of the strong protests of the referees appointed by the Government in 1856. The whole story is told so well in the recent report of the Metropolitan Sewage Discharge Commission, that we need only refer our readers to that valuable State paper. In a sense it is, of course, true that the Board worked under Parliamentary powers, which, however, were exceptionally great; but that the Board suggested and made itself responsible for the scheme, and pressed it with the utmost energy, is no less true than that it has recently spent a large sum of money in the endeavour to prove that no nuisance exists, and that the present state of the river is satisfactory. On April 6th, 1858, Mr. (now Sir Joseph) Bazalgette, and the two engineers appointed by the Board to assist him, advised that Barking and Crossness should be selected for the outfalls, and scouted the suggestion of the referees that the sewage should be taken to Sea Reach in these remarkable words:—"The plan recommended by the referees is needlessly large, excessively costly, and, as a work of construction, all but impracticable." We presume Sir Joseph has changed his opinion on the last point. The simple fact is that the Act of 1858 left the disposal of the sewage of London to the discretion of the Board, subject only to the conditions that the sewage must be taken out of the metropolitan area, and that no nuisance should be created. There was, it is true, one other condition, which, unfortunately, was not inserted in the Act. It is best stated in the words of Mr. Disraeli, then Chancellor of the Exchequer. "We make it a condition with the Metropolitan Board of Works ..... that provision shall be made for such temporary and *permanent* works of deodorisation as the metropolis has a right to require." On the whole, we must agree with the sagacious remark of the *Metropolitan*, that "public writers ought to make sure of their facts before they begin."

THE NEW ENTRIES.

THE following are the numbers of new students at the Medical Schools from which returns have been received:—

	Full course.	Occasional.	Total.
St. Bartholomew's	125	13	138
University College	76	60*	136
London	83	46	129
St. Thomas's	86	24	110
Guy's	68	11†	79

AMERICAN FEELING TOWARDS ENGLAND.

ON his return home from Europe Dr. Shoemaker was entertained by his friends and fellow-citizens at a banquet, at which, in responding to the toast of the evening, he spoke in feeling terms of the universal kindness and courtesy he had received at the hands of his *confrères* in England. "Let me assure you from personal experience," he said, "that English physicians will always be glad to extend to you the right hand of fellowship, to welcome you to their homes, to conduct you through their well-equipped hospitals, and make you feel at home at their meetings. They are the stock whence we sprang; go back to the parent, imbibe some of its practical thoughts, and you will be amply repaid for your visit." In the *Medical Bulletin* Dr. Shoemaker, speaking in his editorial capacity, reiterates these sentiments, and says: "From the moment we landed upon the shores of Great Britain, during our stay upon the Continent, and until our departure, everything was done to make our visit a memorable one. It will be a green spot in our memory to recall in after years; dear with us as long as life continues to

Digitized by Google

exist. Our Transatlantic brethren certainly possess the tact of making their guests comfortable, and it is done with such heartiness and good will that you cannot but help feeling that it is genuine, and that they mean to prove to you that in our grand profession we are all brothers, intent upon doing good, not only to the laity, but to each one of the brotherhood. In taking leave of our kind hosts it is with regret that we have not more warmly expressed our sentiments, and can only conclude with a hearty wish that the opportunity will soon be given us of showing them that we have learned well the lesson of hospitality taught us." We most heartily reciprocate these sentiments, and trust that it will not be long before Dr. Shoemaker and his colleagues again visit our shores.

MUSHROOMS.

THE genial autumn which has now nearly passed has been favourable to the growth of mushrooms, and has not been unmarked by the accidental illnesses which are apt to arise from the use of a food so uncertain in its qualities. Fifteen cases of fatal poisoning from eating mushrooms are reported from France, besides several others, in which death was barely averted. Misfortunes of equal magnitude are likely to happen from time to time, where only some popular chance test, as in the above-mentioned instances, is relied on for their prevention, and slighter forms of indisposition have never been rare under the same circumstances. The order of Fungi contains many poisonous as well as wholesome varieties, and authorities of note have occupied themselves with establishing the grounds of difference between these two great sections. According to them, the noxious forms are distinguished by one or other of the following peculiarities: their rank odour or high colour; their tough or watery flesh, and scaly or spotted surface; their pungent, spicy, or bitter taste; their growing in clusters, and commonly in wet or shady places. The esculent types, on the contrary, are usually white or brownish, not scaly or spotted, dry, brittle, bland, grow singly, and prefer dry pastures. A pale pinkish hue characterises the "gills," or hymenium, of the common edible mushroom, while a dark colour marks those of its poisonous imitator. Of artificial tests, none are very trustworthy. The blackening of a silver coin when placed in the saucepan with the fungus while it is being cooked has been held to indicate danger. It failed to do so in the cases we have referred to, and this is not surprising, for if it have a meaning it is that decomposition has begun and sulphuretted hydrogen has been generated. Many mushrooms, it is clear, are hurtful independently of any such condition, though doubly so if it be present. Uncertainty in selection does not therefore arise from any want of general rules to guide us in distinguishing natural appearances, but from the great difficulty to any but the proficient eye in recognising these when seen, the more so that intermediate forms of doubtful character link together the innocent and the injurious varieties. Poisonous properties, too, are wont to develop in wholesome kinds under certain conditions. Thus gardeners are careful to exclude rotting wood from the soil in cultivating mushrooms for the table, believing that absorption from such substances is hurtful. Some fungi are edible when young, like the puff-ball, but become poisonous as they ripen. Habitat has probably a modifying influence, which is seen in the divergence of the properties of the agaric of open fields from those of the very similar growth which clusters in the shadow of grassy woodlands. The symptoms of mushroom poisoning are more or less familiar to all practitioners of medicine, and need but a passing notice. They are briefly those of an irritant of the digestive tract, sometimes complicated or even in great part replaced by delirium and coma. Treatment must accordingly aim at combining the removal of the poison by emesis or purgation with a sedative action. Prevention is always better than cure, and the public would do well to avoid the use as food of any fungus, especially if exposed for sale, which has not come under the inspection of a skilled and experienced judge.

REDUCTION OF DISLOCATION OF THE SIXTH CERVICAL VERTEBRA.

IN the current number of the *American Journal of the Medical Sciences* Dr. Wiest records a case of dislocation forwards of the sixth cervical vertebra, the reduction of which was attended with apparent benefit. The patient was a man, thirty-three years of age, who was knocked down by the falling limb of a tree which struck him on the left temple. When seen four hours later there was complete motor and sensory paralysis as high as the nipples, only diaphragmatic respiration, and impaired sensation and motion in both arms. The head was extended and rotated to the left side, and there was a deep depression above the seventh cervical spine. Two days after the accident an attempt at reduction was made. The shoulders were fixed, and the head was extended and rotated first to the right and then to the left; a loud snap was heard, and was also felt by the patient, and the cervical spines were found to slide into their proper position. Extension was maintained, but unfortunately the head and shoulders were raised instead of being allowed to lie flat on a firm mattress, with a well-adjusted support for the neck. The patient died on the thirty-fifth day, but the report does not state in any way fully the progress of the case after the reduction, or the mode of death. In addition to the dislocation of the sixth vertebra forwards and to the right, there were three fractures through the right half of the atlas. There was no injury to the cord apparent to the naked eye, but the microscope showed the "connective tissue torn" and the "nerve tubules disarranged." The case is certainly one that encourages surgeons to follow out the same line of practice where there is evidence of the persisting displacement of a vertebra. Although the cord is generally seriously crushed at the moment of the accident, the removal of all pressure upon or irritation of the bruised part is the best way to obviate the ascending myelitis, which is a frequent cause of death.

FEVER AND SANITARY ADMINISTRATION AT NEWARK.

WITH the information that sixty cases of typhoid fever with four deaths have occurred in the borough of Newark, there comes in an account of the meeting of the town council and in a correspondence to the local press a revelation of sanitary administration that is most discreditable. To begin with, one of the aldermen announces to the council that the duties of the inspector of nuisances are to be in abeyance for some months, because his work as collector will take all his time, and this is confirmed by the subsequent reports of the inspector himself and of the medical officer of health. Such a state of affairs would be astounding even if Newark stood at the head of all British towns for health and cleanliness, but the announcement comes at a time when typhoid fever is epidemic; when correspondence to the local press declares the sanitary state of the town to be "a disgrace," and also points to the general existence in the borough of foul matters, refuse, and piggeries; and when the Local Government Board are pressing the corporation as to their polluted wells, as to the dangers to health "associated with the faulty construction and position of privies," as to the "large accumulations of excreta and refuse in the vicinity of dwellings," and as to the insufficiency of closet accommodation. What a town like Newark can have to do with surface wells must be surprising to anyone having the barest knowledge of the first principles of sanitation. The

Digitized by Google

town is an ancient one, on the surface soil of which people have lived for centuries; the old system of cesspools and privy-pits would appear to continue to some extent, and apparently much after the same style, as it doubtless did centuries ago. The surface of the soil is, we gather, besprinkled here and there with those accumulations of refuse to which reference has been made, and sewers and drains have been constructed to course through that soil beneath the surface. Of all the places from which to seek drinking water, we should have thought that such a soil would have been the last one, and yet so tenaciously is this source clung to by some members of the corporation, that even now they are talking of analyses whilst fever prevails, and the medical officer of health reports that "no action has been taken with respect to the polluted wells enumerated in his report." The corporation are, however, by no means in ignorance of the state of affairs which exists, and of its possible consequences. Their medical officer of health is one of the most experienced in the kingdom, and many of the town councillors trust him fully. Notwithstanding this, the state of Newark at present deserves the strongest condemnation, a point evidently felt by at least one worthy alderman, who reminded his fellow-councillors, to whom has been entrusted the health of the inhabitants, that if they were not careful a Government officer might come down and expose the state of the town. Worse things than this might happen to Newark.

SMALL-POX IN THE DIAMOND FIELDS.

EVEN yet the epidemic that has for so long visited the diamond fields gives little sign of relaxing its deadly grip. From a local paper, dated Sept. 6th, we find that the weekly record of the sanitary authorities contains a report of eighty-one cases, thirteen of which were fatal. Nor has the spirit of controversy—we had almost said of animosity—between the medical men of Kimberley abated in vigour. On Sept. 3rd, Dr. Matthews gives "an outspoken opinion on the 'prevailing disease,' the value of fumigation and the cordon." In this he endeavours to show that the name "small-pox" is a misnomer, and that the "so-called small-pox" is non-contagious. His contentions, on the face of them, seem to lack the very essential bases—accurate observation and statement of facts. In the first place, he substitutes a mere assertion for a logical conclusion; then he makes no attempt to prove the opposite of the theory he condemns; and, lastly, he resorts to the argument *ad hominem* to support what, in our way of thinking, is a bad case. Whilst denying that the "prevailing disease" is small-pox, he accuses the Board of Health of the insufficiency of the means taken to arrest its spread. Quite ingenuously he cites a case in which the brother of an affected person is allowed free access to his relative with the result that the disease is communicated to him, or, as Dr. Matthews puts it, he catches it through being exposed to the same causes. What the nature of "the same causes" is there is no evidence to show, not even is reference made to the question. Is it "telluric?" as Dr. Jameson contends; or is it some unknown aerial spirit working evil among the people? Dr. Matthews's remarkable communication is made still more amusing by the addition of some original thoughts on the inefficacy of fumigation. On this latter point he seeks shelter behind some partial experiments made by M. Pasteur, which are recorded in THE LANCET of July 26th, to test the disinfecting power of sulphurous fumes. It will readily be seen that the conditions under which M. Pasteur experimented were not those which are generally, and should always be, taken to prevent the spread of specific contagious disorders. Following closely upon Dr. Matthews's "plain speaking" is a rejoinder from Dr. Sauer, the medical officer of health. Whilst congratulating the latter upon the common sense shown in his dealing with the facts of the case, and upon the acumen with which he argues from these facts, we regret to find this "criticism on an out-spoken opinion" is something more than rhetorical; it is captious. Nothing is to be gained by returning blow for blow; "A soft answer turneth away wrath." We have all along given Dr. Sauer the credit of having recognised the true nature of the Kimberley outbreaks, and with having stood up boldly in defence of his opinions. In future we trust that he and his opponents will make common cause against the common enemy.

THE EPIDEMIC AT KIDDERMINSTER.

WE expressed astonishment a short time back at the mere passing visit which Dr. Parsons had been instructed to pay to Kidderminster; and although the value of a more complete inquiry is somewhat lessened by delay, we are glad to find that he has returned to make a much more exhaustive investigation into an epidemic which, from the nature of its extent, and from the obscurity which surrounded it in so far as causation is concerned, is one of very great public importance. Although the epidemic as such appears to have largely subsided, yet there have already been between eighty and ninety deaths from typhoid fever in the borough, and although the suspected well is now only put to a modified use, yet many of the inhabitants still object to any resort to it whatever, and doubtless but little of the water is consumed. A further investigation as to the precise influence of this water on the health of the town is evidently wanted; and though it might fairly have been expected that when the necessary lines of inquiry had been pointed out to the authority they could themselves, with sufficient skilled aid, have carried out the work, yet it is satisfactory from a public point of view to know that the work will now be done, or at least inaugurated, by an independent official. Much more is also wanted to be known as to the precise conditions which favoured the spread of the disease, and as to the actual conditions of sewerage and drainage which have caused such loud complaint. This information will now probably be forthcoming. In the meantime private charity is doing much. Carriages are provided for poor convalescents, about eighty gallons of milk are daily given away, and many necessaries and luxuries are provided for the sick.

VACCINATION BY UNQUALIFIED ASSISTANTS.

THE *Bradford Observer* of October 16th contains a good report of an action brought by Mr. Edmund Strickland, surgeon, of Halifax, to recover one guinea for medical services, chiefly vaccination of twins and visits, including medicine. The defendant objected to the charge, and alleged that Mr. Strickland agreed to vaccinate the twins for 5*s.*, and brought with him "an inexperienced man who cut the arms too deep" and then wanted to charge 21*s.* Mr. Strickland denied all this. And the magistrate did not seem to believe more of it than that the assistant was unqualified. He reflected severely on Mr. Strickland for allowing an unqualified practitioner to perform the operation, especially when there was abroad so much unreasonable prejudice against the operation. He allowed only 6*s.* for visits and disallowed the charge for the operation. The case is somewhat unfortunate. We do not doubt that the operation was well done and will protect the defendant's children from small-pox, for which he should be more grateful. But for legal purposes it was a mistake to take the case into court. The law is explicit enough, and properly so, in requiring a vaccinator to be qualified. An unqualified assistant might possibly be a better vaccinator than his qualified principal, but the law takes no notice of exceptional facts, and should not have been relied on to do so.

CLOSET TESTING AT THE HEALTH EXHIBITION.

THE members of the Jury No. 9, undoubtedly the hardest worked jury at the Health Exhibition, have only just completed their labours. Theirs was the truly sanitary section, for it embraced all that related to house and town drainage. But, not content with carefully examining all the exhibits, they felt, and justly, that practical tests were absolutely necessary before a definite opinion could be pronounced. More than 300 experiments have been made of hydraulic rams, pumps, valves, waterclosets, and traps. No less than 120 exhibitors expressed their readiness to send their closets to the testing house, but when the nature of the crucial experiments was generally known, the number gradually dwindled down to seventy-one. The experiments involved the answering of thirty-three different questions, comprising the precise measurement and form of each closet, the amount of water held in the pan, in the trap, and in the waste preventer, the pressure of water when it comes direct from the main, the size of the delivery pipe, of the exits to the soil pipe, the means of ventilation, the depth of the dip in the water seal, the force required to set the closet in action, the number of seconds taken to flush the closet, &c. The efficacy of the working was tested by placing four pieces of paper, a sponge, and ten small apples in each closet. These objects were all to be carried away both from the pan and the trap by a single flush. After this the sides of the pan were painted over with black plumber's soil or paint, and the closet tried, to see if one flush would wash all the paint away. This was a very severe test, as the paint was daubed on right up to the rim of the pan. The practical result of these experiments has been to demonstrate that it was nearly impossible to wash the pan thoroughly and to clear the trap with less than two gallons of water. As each closet took nearly half an hour to test, the work that these experiments involved may be readily surmised, and the jury deserve the warmest praise for the trouble they have taken in the conscientious fulfilment of their duty. One fault only can be found—namely, that the experiments with the closets were of a purely national description, and, as such, not in keeping with an international exhibition. All the thirty-three questions apply to waterclosets; but, speaking internationally, the enormous majority of mankind do not use waterclosets, and have never even seen such contrivances. In by far the greater number of towns as at present organised throughout the Continent and the East, there are no waterclosets, no water-supply, and a two gallon flush is absolutely out of the question. We trust that the jury, in their report, will acknowledge this fact, so as not to appear too insular in their ideas.

"ADJOURNED INQUESTS."

AN annotation headed as above, which appeared in our last issue, was suggested by what had recently transpired at an inquiry into the cause of death of the Rev. W. Spencer Edwards. It will be remembered that an adjournment was decided upon owing to the jury not being satisfied with the medical evidence. Since then a second post-mortem examination has been made, the result of which completely confirmed the truth of the opinion expressed in the first instance—viz., that death was due solely to heart disease. But to their verdict, which was warranted by the medical testimony, the jury added a rider which tells very unfairly on Mr. Keele, the gentleman in whose house Mr. Edwards died. The deceased, although under the general care of Mr. Keele, was attended by his medical man, Mr. Tait. The latter gentleman enjoined perfect repose, and it was in the course of carrying out the instructions given to him that Mr. Keele declined to allow a daughter of Mr. Edwards to have an interview with him. We are glad to find that the summing up by the coroner, Dr. Diplock, and his subsequent remarks were not in agreement with the finding of the jury, "that death was hastened by the refusal of those in charge to allow deceased to see Mrs. Hanmer and a solicitor." We maintain that such a conclusion was not in accordance with the evidence as reported, and that the stigma incidentally cast upon Mr. Keele was unmerited.

SMALL-POX AND ENTERIC FEVER IN THE NORTH.

OUR Newcastle correspondent writes:—Small-pox continues to spread in the city; there are at present thirteen cases in one street alone. The disease is fortunately mild in type, but we hear of its extending to the adjacent colliery villages. Every effort is being made by the authorities to check the spread of the infection, but the ignorance or carelessness of the poor on the subject is lamentable. For instance, a woman attended the police court the other morning who admitted, in reply to a question from the chief constable, that she had at that time three children suffering from small-pox at home.

Several cases of enteric fever have prevailed at the east end of North Shields, and there are at the present time twelve cases in the fever hospital; measures are being taken by the authorities to prevent the spread of the disease. The water-supply should be well looked to, for it will be remembered that the town suffered severely from this source a few years ago. Many people think that the reservoirs are too near the town to be safe, and that the water is not sufficiently exposed to pure air to cause its safe oxidation; however, it is certain that the town always contrasts unfavourably as to health with its sister borough, South Shields, which has its water-supply from a different source.

OUR MILITARY PRISONS.

WE regret that we are again obliged to comment in most unfavourable terms on the manner in which the information respecting the health of the soldiers confined in the military prisons is given—it would be more correct to say withheld—in the annual Report of the Inspector-General. Last year we were informed that steps were being taken to improve the mode of compiling the statistics on this head. This year it is stated that "steps have been taken, with the aid of the medical inspector of the convict and local prisons, to bring about greater uniformity of procedure in filling up the returns, and it is believed that the figures from the different prisons now represent such cases as would be deemed hospital cases in the civil prisons—i.e., cases requiring *bonâ-fide* hospital treatment, and not merely trivial cases needing only some simple remedies. They represent therefore similar and comparable facts." But something more than this is wanted as regards military prisoners. It is not a comparison of the health of military with that of civil prisoners that is required, but the means of ascertaining in what respect the health of soldiers in confinement is affected as compared with their comrades doing duty. And this is not afforded by the Inspector-General's returns. But there are also other defects to be remedied. In the table of the "Return of Sickness" the percentage of the cases is calculated on the total number of prisoners who were confined for any period during the year, instead of on the average number of prisoners. The result of course is to show a very low percentage of sickness, but it is completely misleading. We do not know in what terms the instructions of the medical inspector referred to were issued, but the result is unsatisfactory, as we find twenty-three cases returned as the aggregate number in Chester, while the medical officer in

Digitized by Google

his report says, "There were only 188 cases of sickness amongst the prisoners." Again, the column for deaths has been omitted from the table; and the number constantly sick, which is an important element in the statistics of health, finds no place in the returns. It is much to be desired that some arrangement might be made by which these reports on military prisons should afford the requisite information to enable us to estimate the effects of imprisonment on the health of soldiers. This could be done without any difficulty if the Inspector-General would put himself in communication with the Director-General of the Army Medical Department. We commend the subject to the notice of those members of the House of Commons who take an interest in military questions, with a view to their bringing under the notice of the Secretary of State for War the very unsatisfactory manner in which information is at present furnished. In addition to the number of cases treated in hospital, and as casual sick in the wards of the prison, it would be most desirable to have a return of the diseases for which they were treated; the deaths occurring, whether in hospital or the prison; and the mean daily sick in each prison.

SIR MOSES MONTEFIORE.

THE Patriarch of Israel in these latter days, as Sir Moses Montefiore may well be held to be, attained his hundredth year yesterday, and with him old age brings honours and troops of friends who hail him father. Lives such as that of this great and good man are lessons of love and righteousness to mankind. Probably the gracious deeds of Sir Moses Montefiore have done more to raise his people to their proper level in the estimation of statesmen and philanthropists in all contemporary communities than could have been achieved by any other means, save the calm and patient well-doing and the liberality and geniality of personal feeling and conduct which have been consistently exemplified in his well-spent life. It is rarely in any age that a man of note reaches his centenary amid circumstances so propitious and evidences of kindly and reverential friendliness so sincere.

ROYAL UNIVERSITY OF IRELAND.

A MEETING of the Convocation of this University takes place this week. Notice of the following motion has been given by Mr. Maguire, LL.D., F.L.C.D.:—"That, in the opinion of Convocation, steps should be taken with reference to Dr. W. K. M'Mordie's statement that the examination papers of the Royal University are known beforehand to certain candidates, and that there is much to confirm Dr. M'Mordie's statement." The allegation is a very serious one, and has already been referred to by our Dublin correspondent when commenting on the Report of the President of the Queen's College, Belfast, for the past session.

THE SURGICAL FINGER-NAIL.

A SMALL brass instrument of simple construction was shown by M. Motais at the recent French Congress held at Blois. It consists of a metallic plate which has the shape of the finger-nail, which it covers, the finger itself being engaged by means of a ring. The author has employed it for the removal of glands from the axilla in cases of cancer of the breast, and states that it would be found useful in the removal of uterine polypi as well as in stripping the periosteum from a bone. The small instrument does not, like that of Amussat, pass beyond the level of the finger-nail.

THE outbreak of typhoid fever at Derby still continues to show signs of abatement.

SCIENCE has to regret the death of Dr. Heinrich Neumann, Professor of Psychology at the University of Breslau, in his seventy-first year. He was recognised in Germany as one of the leading authorities on mental disease. Besides his contributions to strictly professional literature, he had also, by various monographs, especially one on Lear and Ophelia, taken a place among the numerous contributors in Germany to Shakspearian criticism.

THE death is announced of Mr. Charles Barham, the oldest physician in Truro, at the age of eighty. Mr. Barham graduated as M.B. at Cambridge in 1827, and afterwards studied in Edinburgh and Paris. In 1860 he proceeded to the degree of M.D. He was a Justice of the Peace for Truro, a Vice-President of the Royal Institution of Cornwall, and Consulting Physician to the Royal Cornwall Infirmary.

THE Metropolitan Board Teachers' Association has passed the following resolution, which is stated to represent the opinions of 2078 adult board teachers in 320 London schools. "The Metropolitan Board Teachers' Association endorses generally the report of Dr. Crichton Browne on the over-pressure and worry in schools, and thanks him for the report."

DR. WM. GONNERMANN, the joint author with Professor Rabenhorst of the Mycologia Europæa ("The European Fungi"), a highly valued work, died a few days ago at Coburg, at the age of seventy-eight. The last few years of his life were spent in an extended study of the cryptogams, and it is hoped that his notes will be a very valuable accession to the existing knowledge on this subject.

AN experimental and clinical study on a new method of producing anæsthesia is the subject of a work, recently published, from the pen of M. Colombel. A combination of atropine (two centigrammes), morphia (twenty centigrammes), and chloroform (twenty grammes) is the mixture recommended. Some of the surgeons at Lyons speak very favourably of its use.

AT the first meeting of the Berlin Medical Society on the 15th inst., the President, Prof. Virchow, referred to the conference upon cholera held in July, when Dr. Koch detailed his experiences upon the cholera and its bacillus. He added, that in spite of recently published statements, Dr. Koch still adhered to his belief in the specificity of the comma bacillus.

SMALL-POX has appeared in various parts of Victoria, especially near Melbourne. Should the disease become general in the colony, as there is too much reason to fear will be the case, "the mortality among our practically unvaccinated population," says the *Australian Medical Journal*, "will be something appalling."

BY a unanimous vote, Dr. William Osler of Montreal has been elected to the chair of Clinical Medicine in the University of Pennsylvania, in the vacancy created by the transfer of Dr. Pepper to the chair of Theory and Practice of Medicine.

THE French lady medical students have an active champion in M. Paul Bert, who is seeking to secure for the ambitious fair ones the privilege of attending the wards of the Paris hospitals.

WE regret to announce the death from cholera of Surgeon-Major Mark Anthony, M.D., of the Army Medical Service, which took place at Fatehgurh in India on August 28th.

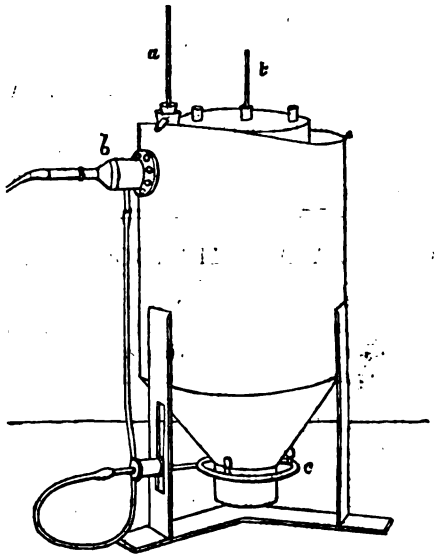
THE

BIOLOGICAL LABORATORY AT THE HEALTH EXHIBITION.



No. VII.

INCUBATORS.

FOR the purpose of maintaining cultivations at a constant moderate temperature, such as that of the human body, incubators of various kinds are employed. Two are in use in the laboratory.

The étuve d'Arsonval (Fig. 27) is a cylindrical vessel with double walls. The walls contract below in a conical shape. The interior of the incubator communicates with the exterior by means of an aperture at the bottom of the vessel, which is closed by a grating, and there is a perforated floor at the junction of the cylindrical and conical parts which support the objects placed in the interior. The cylindrical part of the apparatus comes to a termination above in a plane which is slightly oblique, and it is at the highest part that the aperture is placed, through which the space enclosed between the walls is filled with water. This arrangement allows the space to be completely filled without any air being enclosed, which, as will be seen, is essential to the proper working of the apparatus. The aperture

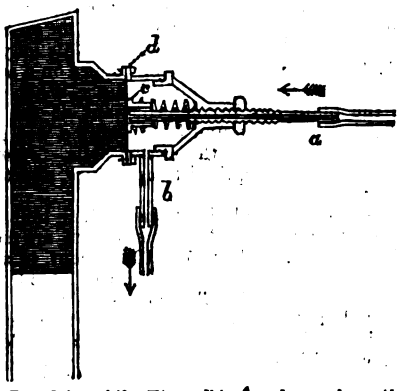


FIG. 27.

The Etuve d'Arsonval.
a, Pressure tube. *b*, Regulator. *c*, Burner. *t*, Thermometer.

mentioned is closed by a caoutchouc stopper, which is perforated by the end of a narrow glass tube (*a*). The interior is closed above by a lid which, like the sides, is double to contain water, and is in a horizontal plane. It is perforated by several apertures, one of which admits a thermometer (*t*). The apparatus for regulating the supply of gas (*b*) is attached to the side close to the upper part of the wall. A section of it is represented at Fig. 28. A hole in the outer of the two walls of the incubator is surrounded by a ring which has a flat lip. To this is applied the corresponding lip of a sort of box. The two lips, however, are not in actual apposition, for they are separated by the margin of a diaphragm of indiarubber (*d*) which intervenes between the water enclosed in the double wall of the incubator and the cavity of the box. It will be convenient to regard the diaphragm as forming the floor of the box. Its sides are vertical, and its top which is screwed on to the sides is conical, being perforated in the middle by a long pipe (*a*), which again can be screwed backwards and forwards in the top. This tube (*a*) projects in the cavity of the box so that the end of it approaches the diaphragm. Round the end of *a* is a loosely fitting collar (seen in section at *c*), which is kept applied to the diaphragm by means of a spiral spring. From the lowest part of the side of the box passes down a tube (*b*). An indiarubber pipe attached to *b* is in connexion with a circular pipe which surrounds the lower part of the incubator, and is provided with three burners by which the apparatus is heated. The gas enters through the tube *a* (fig. 28), and escapes between its mouth and the diaphragm into the cavity of the box, whence it passes through *b* to the burners. When the water is heated it expands, and as it completely fills the space between the walls of the incubator it at once begins to rise in the tube represented at *a*

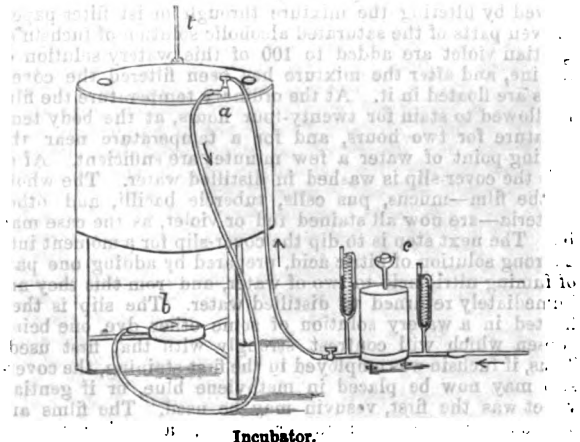

FIG. 28.

The Regulator of the Etuve d'Arsonval, seen in section.
a, Afferent Gas-pipe. *b*, Efferent Gas-pipe. *c*, Collar. *d*, Diaphragm.

in fig. 27. Now the pressure on the diaphragm exercised by the water in this tube is equal to the weight of a column of water of which the diaphragm is the base, and the distance between the surface of the water in the tube and the diaphragm is the height. This pressure causes the diaphragm to bulge outwards towards the mouth of the tube supplying the gas. When the temperature has attained the required height the tube *a* (fig. 28) is screwed inwards until its mouth is so near the diaphragm as to partially shut off the supply of gas. When this is done the temperature of the water falls, less pressure is exerted on the diaphragm, and it

FIG. 29.

Incubator.
a, Regulator. *b*, Gas-burners. *c*, Pressure regulator. *t*, Thermometer.

recedes from the mouth of the tube, so admitting a larger supply of gas. In this way the pressure exercised by the heated water is made to check the heating of the water, and by adjusting the mouth of the supply tube relatively to the diaphragm, any desired temperature, within the limits of working of the apparatus, may be maintained constant, or at least with variations only within half a degree.

The other form of incubator is represented at Fig. 29. It is a cylindrical box with double sides, floor, and lid, and these enclose water. It is heated from below by means of a gas burner (*b*). It is regulated by Reichert's regulator (*a*), by means of which the heated water causes the mercury

Digitized by Google

enclosed in a bulb immersed in it to rise in a tube and check the supply of gas. The principle is similar to that of Page's regulator. The pressure of the gas is rendered constant by means of the regulator (*c*).

METHODS OF STAINING BACTERIA.

In order to stain bacteria from a cultivation, or when they are present in a liquid, a small portion of the cultivating material or of the liquid, containing them is placed on a thin cover-slip, another cover-slip is placed over this, and the two are firmly pressed together. The two slips are then slid one from the other, and each with a very thin layer on it is set aside to dry. In preparing to stain, the cover-slip is first heated, either by being passed three times rather slowly through the flame of a spirit lamp or else by being gently baked for an hour at a temperature of about 110° C (100°–120°) This may be done conveniently by arranging a plate of copper on a stand and heating one end of it with a spirit lamp. When the temperature of the plate has become constant at the different parts, the boiling-point is found by drawing a wet glass rod over it and noticing where the water boils. Just beyond this is the region of the required temperature, and the cover-slips are arranged here.

The aniline dyes, methyl violet, methylene blue, fuchsin, gentian violet, vesuvin, and Bismarck brown are commonly employed for staining. About 5 to 10 per cent. of a concentrated alcoholic solution of one of these is added to water and the mixture is filtered. The cover-slip which has been heated is floated on this solution with the film downwards until it is stained, after which it is washed in distilled water, dried, and mounted in Canada balsam. In order to obtain a finer preparation, the cover-slip may be left longer in the staining solution and then immersed in a dilute solution (½ to 1 per cent.) of acetic acid. This removes some of the colour. It is then washed and mounted as before. An alkaline solution of methylene blue is better for the bacteria associated with glanders, typhoid fever, and some others. This is prepared by adding thirty parts of a saturated solution of the dye to one hundred parts of a dilute solution of caustic potash (1 in 10,000).

Tubercle bacilli may be demonstrated in sputa in the following way:—Some of the thicker parts of the sputum is placed on a cover-slip and dried and heated in the manner above described. After it has been so treated it is stained in a solution of fuchsin or gentian violet prepared by the Weigert-Ehrlich method. To prepare such a solution water is shaken up with aniline oil until it is saturated with it; it takes up about 3 per cent. The undissolved oil is removed by filtering the mixture through moist filter-paper. Eleven parts of the saturated alcoholic solution of fuchsin or gentian violet are added to 100 of this watery solution of aniline, and after the mixture has been filtered the cover-slips are floated in it. At the ordinary temperature the film is allowed to stain for twenty-four hours, at the body temperature for two hours, and for a temperature near the boiling-point of water a few minutes are sufficient. After this the cover-slip is washed in distilled water. The whole of the film—mucus, pus cells, tubercle bacilli, and other bacteria—are now all stained red or violet, as the case may be. The next step is to dip the cover-slip for a moment into a strong solution of nitric acid, prepared by adding one part of fuming nitric acid to two of water, and from this they are immediately returned to distilled water. The slip is then floated in a watery solution of some other dye, one being chosen which will contrast strongly with that first used. Thus, if fuchsin was employed in the first staining, the cover-slip may now be placed in methylene blue, or if gentian violet was the first, vesuvin may be used. The films are stained for half an hour or longer, according to the strength of the solution, and are then washed, dried, and mounted in Canada balsam. The result of this process is that the tubercle bacilli remain stained by the first dye used, while all the rest of the film has been so acted on by the nitric acid that the first dye is replaced by the second, and thus the tubercle bacilli stand out red on a blue ground, or violet on a brown ground, as the case may be.

A *tissue* which contains bacteria should be hardened in absolute alcohol or methylated spirit; in the former case for one or two days, in the latter for two or three weeks. When sections are cut it is best to freeze the tissue. It is first soaked in water until the alcohol is removed—i.e., until it sinks, in all cases except lung specimens—and then in strong gum. The solution of gum may conveniently be kept sweet by adding a little salicylic acid to it. When an ice and salt freezing machine is used, the pure solution of gum sets to too brittle a mass to be cut without injuring the sections; in order to prevent this five or ten minims of methylated spirit may be added, or a mixture of two parts of gum and one of syrup may be used. In an ether freezing machine the required consistence of the mass may be obtained by moderating the supply of spray. The sections are floated in water to dissolve the gum. The best stain for most bacteria in tissues is the alkaline solution of methylene blue above described. After being stained from one to two hours they are washed in dilute acetic acid, then successively in distilled water, absolute alcohol, and oil of cedar, and mounted in Canada balsam. The oil of cedar takes out the colour less than oil of cloves. The watery solutions of fuchsin, methyl violet, and gentian violet may also be used.

In order to stain the bacteria one colour and the tissue another, the sections may be placed first in methyl violet, or gentian violet, and then in picrocarmine; but this method requires considerable practice. Gram's method is for the same purpose, and in many cases gives good results. The sections are transfered from water to absolute alcohol, and thence to a Weigert-Ehrlich solution of gentian violet, for from one to three minutes. In some cases it is better to place the sections in absolute alcohol between this and the next stage. They are then placed in a solution composed of one gramme of iodine, two grammes of iodide of potassium, and 300 cubic centimetres of water, where they remain for three minutes or more, and are then passed on to absolute alcohol, oil of cloves, and Canada balsam. The bacteria are stained violet and the tissue pale yellow. In order to deepen the colour of the tissue the section may be immersed for a moment in vesuvin solution after the alcohol bath succeeding the iodine solution. It is then placed in alcohol and oil of cloves, and mounted in Canada balsam. Sections of tubercular tissue may be treated by the nitric acid method in the same way as the cover-slips. After the second stain they are passed through absolute alcohol and oil of cloves, and mounted in Canada balsam.

In staining sections for photography, a saturated watery solution of vesuvin is used, the brown colour coming out dark on the plate.

CHOLERA AND ITS PROGRESS.

FOR the past fortnight there has been a further diminution of the cholera mortality in Naples, but it has been by no means a steady one, the deaths having varied from thirteen to seventy a day, and it is to be feared that some time must yet elapse before the disease will have ceased to exist in the city. Up to the 20th inst. the deaths that had been admitted by the official records exceeded 6500 in the city, in addition to over 700 in the province of Naples. The other provinces to which the disease clings with most tenacity are those of Genoa, Cuneo, Bergamo, and Cremona; but with the exception of Genoa, from which information does not come very regularly, the mortality is a diminishing one, and there are grounds for hoping that, even so far as the town of Genoa is concerned, a very material abatement in the virulence of the outbreak has taken place.

From France the news is more cheering than it has hitherto been since the commencement of the epidemic. Only very occasional deaths are now occurring in either Toulon or Marseilles, and although a somewhat persistent prevalence of cholera was maintained in the Department of the Pyrénées Orientales during the earlier half of the present month, yet an absence of news as to fresh deaths in that portion of France may, it is to be hoped, be taken as an indication that the outbreak has practically subsided.

Much the same may be said as regards the Spanish outbreak. Up to about October 10th a daily return of cholera deaths was made as regards the province of Alicante, where the disease first appeared, and where the mortality was largest; but now, although no authoritative announcement has been made as to the cessation of the epidemic, the absence of news gives some hope that this result may, at least, be near at hand.

As regards the future, there is some hope that the terrible visitation of 1884 will not be thrown away. From Naples comes news that early steps are to be taken to secure the proper sewerage of the city, and to enforce the closure of the

Digitized by Google

many wells which are resorted to, and which must obviously from their surroundings be subjected to constant pollution. But much more than this is needed in Naples, and it is perhaps in part owing to the gigantic scale on which sanitary reform is needed that so little improvement followed on the previous epidemics which devastated the city. The overcrowding of houses in area and of people in dwellings is such that purity and wholesomeness of air cannot possibly be secured, and, together with a reconstruction of much of the town, there must proceed the erection of buildings to take in those who will be ejected from the old tenements. Whether Naples can undertake this large task except with the aid of the national purse has to be seen. But until it is undertaken the city will remain a source of danger to the Peninsula.

Public Health and Poor-Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Hampstead.—The parish of St. John, Hampstead, not only continues to enjoy a small death-rate, but after making allowances for the deaths of non-parishioners in public institutions, the rate for 1883 is reported by Dr. Gwynn as being the lowest on record—namely, 11·26 per thousand. The zymotic death-rate was also low. As regards the influence of the North-western Hospital of the Asylums Board in the district, Dr. Gwynn states that there has been no special incidence of scarlet fever in its vicinity. He attributes this in a very great degree to the fact that a severe epidemic during the two previous years had used up the material necessary for its development; but it must, at the same time, be admitted that, quite apart from this condition, a careful administration has all along prevented any spread of this disease in the neighbourhood of the London Fever Hospital. Since the end of 1883 small-pox wards have also been opened at Hampstead, but the number of patients is to be limited to forty. The question of the efficient removal of house refuse bids fair before long to become a pressing one in Hampstead, as it has done elsewhere in the metropolis and in large centres of population, and it is anticipated that the difficulty will have to be met by the erection of a destructor. The provision of baths and washhouses is in contemplation, and improvements in the ventilation of the sewers are about to be undertaken.

Islington.—In St. Mary's, Islington, the death-rate was 17·1 and the birth-rate 32·8 per 1000 in 1883. Passing from statistics, Dr. Tidy gives some account of the epidemic of enteric fever which prevailed mainly in St. Pancras last year, which was due to milk infection, and which spread also into the Islington district. An account follows as to the other infectious diseases which prevailed, there is a short summary of the sanitary work of the year, an account of the quantity and quality of the water supplied to the district, and then follow the four quarterly reports issued during the year as to proceedings taken under the Sale of Food and Drugs Act.

Kensington.—During 1883 the death-rate for Kensington was 15·5 per 1000, a lower rate than any known since vital statistics for the parish have been available. In dealing with the prevalence of infectious diseases in the parish, Dr. Dudfield shows that considerable care is taken by his department to prevent the spread of infection, employers being communicated with in the case of persons having scarlet fever in their houses, and other kindred precautions being taken. Reference is made to an outbreak of enteric fever which occurred last autumn in the neighbourhood of Earl's Court-road. The prevalence appeared almost certainly to be associated with a special milk service; but though every facility for an investigation was rendered, the actual source of the infection was not discovered. The existence of the Fulham or Western District Hospital in the immediate vicinity of an important portion of the Kensington district leads Dr. Dudfield to report in detail as to the operations of the Metropolitan Asylums Board, and he next proceeds to consider a localised outbreak of small-pox which occurred in the vicinity of that hospital during the course of the past summer. This outbreak led to a renewal of Mr. Power's investigations as to the influence of the Fulham hospital, but according to Dr. Dudfield the prevalence had commenced before any patients were admitted into the hospital. If this be so, the information to be derived from the inquiry will probably be limited, but Mr. Power's report must be waited for before any definite opinion on the subject can be expressed. In the absence of any system for the compulsory notification of infectious diseases, a plan has been arranged by which Dr. Dudfield receives a large amount of voluntary aid in this matter from registrars, relieving officers, the resident medical officer of the Kensington Dispensary, the Chief Commissioner of Police in so far as constables and their families are concerned, the postal authorities in connexion with postmen and their families, school authorities, clergymen, district visitors, and many private medical practitioners. From one or other of these sources several hundred cases of illness annually come under notice, and much useful work results; but still the number of concealed cases remains very large, and no voluntary system can be expected to be thoroughly efficient. These and other points of general sanitary interest are fully discussed in Dr. Dudfield's report, but at the same time he does not fail to supply a large amount of information as to the local circumstances of his district, and also to indicate the directions in which sanitary action has been taken. The Kensington reports are, in short, amongst the most complete that are issued.

St. Giles.—Mr. Lovett reports a death-rate of 21·5 per 1000 for the district of St. Giles and a birth-rate of 30·7; the zymotic rate was 2·20 per 1000, or somewhat below that for London generally. Reference is made to a heavy zymotic death-rate in the Peabody Buildings in Great Wild-street. Careful examination of the premises failed to discover any sanitary evil, and in view of the fact that the majority of the deaths were due to diseases such as measles, the circumstance, affecting as it did only a population of some 1500, must probably be regarded as exceptional, and as having but little bearing on the healthiness of the buildings. Considerable improvements have been effected in St. Giles's, as regards dwelling accommodation, during recent years, and more work of the same description is in contemplation. In the general report issued by the Board of Works for this district we note with regret that the erection of public retiring rooms for females has been opposed and deferred, and that no present effort is to be made to meet this crying want in a city which is so vast in area that the need for supplying it is greater than anywhere else.

Wandsworth.—Taking the district as a whole, the birth- and death-rates were 35·1 and 17·8 per 1000 respectively, and the rate of mortality from the so-called principal zymotic diseases was lower than in any of the last seven years. The general sanitary work of the year is stated to have been greater in amount and of more importance than that which has hitherto been accomplished. It included a detailed inspection of dwellings, the removal of a large number of nuisances, and measures to prevent the spread of infection. The scavenging of the district, however, remains very imperfect, and considerable inconvenience and nuisance is hence occasioned to householders. Following on the general report is a separate one by each of the five medical officers of health. In the report on the Putney and Roehampton division reference is made to a serious epidemic of diphtheria which caused twenty-four deaths. Unfortunately, however, the investigation which followed failed to show how the disease had been brought about. In West Battersea complaints were made by the inhabitants as to the dirty and unwholesome state of the water; this was, on inquiry, found to be due to the fact that the dead end of a water-pipe had long remained uncleaned, and when it was first opened the fluid which came forth was for several minutes of a most filthy description. This dead end has since been done away with, the circle being completed by joining the pipe on to another one.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

During the week ending the 18th inst., 6060 births and 3545 deaths were registered in twenty-eight of the largest English towns. The annual rate of mortality in these towns, which had been 20·1 and 19·8 per 1000 in the two preceding weeks, rose last week to 21·1. During the past three weeks of the current quarter the death-rate in these towns averaged 20·3 per 1000, against 20·7 and 19·4 in the corresponding periods of 1882 and 1883. The lowest rates last week in these

Digitized by Google

towns were 13·6 in Halifax, 14·9 in Portsmouth, 16·6 in Brighton, and 16·7 in Hull. The rates ranged upwards in the other towns to 26·9 in Newcastle-upon-Tyne, 28·2 in Liverpool, 29·9 in Preston, and 30·2 in Bolton. The deaths referred to the principal zymotic diseases in the twenty-eight towns included 167 from diarrhœa, 74 from scarlet fever, 68 from "fever" (principally enteric), 56 from whooping-cough, 39 from measles, 33 from diphtheria, and 14 from small-pox. These diseases caused the lowest death-rates in Portsmouth and Huddersfield, and the highest in Derby, Preston, and Bolton. The highest rates of mortality from scarlet fever were recorded in Leeds, Sheffield, and Cardiff; from measles in Bolton; from whooping-cough in Sunderland and Nottingham; and from "fever" in Plymouth and Derby. The 33 deaths from diphtheria in the twenty-eight towns included 21 in London and 4 in Liverpool. Small-pox caused 10 deaths in London (exclusive of 18 London cases registered outside Registration London), 2 in Sunderland, 1 in Liverpool, and 1 in Birkenhead. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had been 536 and 504 in the two preceding weeks, rose to 555 on Saturday last; the new cases admitted were 144, against 129, 106, and 68 in the three previous weeks. The deaths referred to diseases of the respiratory organs in London, which had risen from 159 to 227 in the four preceding weeks, further increased last week to 286, but were 34 below the average. The causes of 71, or 2·0 per cent., of the 3545 deaths in the twenty-eight towns last week were not certified, either by a registered medical practitioner or by a coroner. The largest proportions of uncertified deaths were recorded in Sheffield, Bristol, Preston, and Birkenhead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which in the two preceding weeks had been 21·1 and 22·8 per 1000, declined to 21·3 last week, and slightly exceeded the mean rate during the same period in the twenty-eight large English towns. In the Scotch towns the rates last week ranged from 12·5 and 16·8 in Leith and Perth to 23·2 in Paisley and 25·2 in Aberdeen. The 514 deaths in the Scotch towns included 23 which were referred to diarrhœal diseases, 18 to measles, 18 to scarlet fever, 18 to whooping-cough, 13 to "fever," and 11 to diphtheria; in all, 101 deaths resulted from these principal zymotic diseases, against 137 and 120 in the two preceding weeks. The 101 deaths were equal to an annual rate of 4·2 per 1000, which was 1·5 above the average rate from the same diseases in the twenty-eight English towns. The 96 deaths referred to acute diseases of the respiratory organs in the eight Scotch towns showed a considerable increase, and were 11 above those returned in the corresponding period of last year. The causes of 72, or 14 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 26·3 and 28·8 per 1000 in the two preceding weeks, further rose to 30·2 in the week ending the 18th inst. During the first three weeks of the current quarter the death-rate in the city averaged 28·4 per 1000, the rate for the same period not exceeding 18·1 in London and 17·6 in Edinburgh. The 203 deaths in Dublin last week showed an increase of 9 upon the number in the previous week, and included 25 which were referred to the principal zymotic diseases, against 49 and 32 in the two preceding weeks; of these, 10 resulted from diarrhœa, 10 from "fever," 5 from scarlet fever, and not one either from small-pox, measles, diphtheria, or whooping-cough. These 25 deaths were equal to an annual rate of 3·7 per 1000, the rate from the same diseases being 1·8 in London and 3·6 in Edinburgh. The deaths referred to "fever," which had been 8 and 4 in the two previous weeks, rose last week to 10, and exceeded the number recorded in any preceding week of this year. The 5 fatal cases of scarlet fever were 6 less than in the previous week. Six inquest cases and 4 deaths from violence were registered during the week, and 54 deaths occurred in public institutions. The deaths of infants showed an increase, while those of elderly persons slightly declined. The causes of 29, or nearly 13 per cent., of the deaths registered during the week were not certified.

Correspondence.

"Audi alteram partem."

STOPPING TEETH AT GENERAL HOSPITALS.

To the Editor of THE LANCET.

SIR,—Every dentist who has held a hospital appointment will agree with the statements of Mr. Fitzroy Benham in THE LANCET of to-day; but it is only the dentist who is able fully to realise the vast amount of suffering which dental diseases inflict upon the poorer classes. This suffering, because it does not involve direct danger to life, is usually made light of; yet it is often enough alone to make life as miserable as it can be made by any kind of physical torment. It would be a good thing for the poor, as well as for medical and dental students, if the dental departments of general hospitals could be so extended as to allow of the performance of all operations, including stopping teeth. This is impossible while the present rule exists of having only one dentist on the staff, and no properly organised corps of dental dressers. To prepare and fill a simple cavity of decay will occupy an expert operator on an average half an hour, and when an exposed pulp or other complication is present several sittings of equal length may be needed. Want of time, therefore prevents, as a rule, at present the hospital dentist from doing more than extract teeth in cases of acute toothache. There seems no reason why every hospital should not have on its staff two or three assistant dental surgeons; there is no lack now of qualified and accomplished young practitioners eligible for such posts. These assistants could in most hospitals train a body of advanced students capable of dealing with much of the dental disease which presents itself.

The dental department, like every other department of our general hospitals, is frequented by a large proportion of patients well able to pay for professional services. Would you allow me to add in this connexion a word on behalf of the young struggling dental practitioner, to whom such patients with their small fees would be welcome. The dental schools are now turning out annually numbers of first-rate practitioners, many of whom commence practice in London and other large towns. These, being professional men, are compelled to be modest in their demeanour, and cannot effectually compete in attracting patients with the blatant advertiser who, until the Dentists Act has fully developed its effects, must, it seems, be allowed to prey upon the unwary public. If medical practitioners would but inquire, they might now find in most districts a duly qualified dentist able and willing to undertake many cases which are improperly sent to a hospital, where, for the reasons stated, they often of necessity receive inadequate assistance.

I am, Sir, yours obediently,

Wimpole-street, October 11th, 1884. HENRY SEWILL.

To the Editor of THE LANCET.

SIR,—The question raised by Mr. R. Fitzroy Benham in your issue of October 11th is one of considerable interest, but I think in his enthusiasm he rather oversteps the mark when he implies a ruthless slaughter of teeth (which might be filled) by the dental surgeons of general hospitals. I am happy to inform him that innumerable cases are sent to the dental hospitals in London by such dental surgeons. He is right, however, in saying that the general hospitals as a rule are unable to cope with the question of stopping teeth for the patients at all extensively, and I should like to point out the chief difficulties in the way of such operations. At some of the hospitals tooth-stopping is carried out by the dental surgeons as a means of demonstration, though not as a means of treatment, and for the reason that for a tooth to be "stopped" successfully an outlay of at least half an hour must be devoted to one operation—that is, one tooth; and where, say, ten patients attend each requiring three or four "stoppings," it is obviously quite impossible for the dental surgeon to attempt this himself. Then, as to the question of medical students performing the stoppings themselves, I would say that the time necessarily employed by such a student would be at least an hour under constant supervision; here, again, stopping as a means of treatment is impracticable. But I would further say that we at the Dental Hospital of London

Digitized by Google

never allow a new student to touch a patient until he has been two months at the hospital, during which time he attends demonstrations, watches his seniors at work, and practises "filling" holes drilled in ivory or in extracted teeth. He is then only allowed to commence on very simple cases, and his whole training in the various dental subjects taught in the dental hospitals extends over two years out of the four he must spend over his curriculum for the L.D.S., the other two years being employed in his medical studies and in the dental workroom.

It will thus be obvious that very great care is taken to secure efficiency in dental operations, and it will be equally obvious that the very rudimentary dental knowledge of, and the very elementary dental operations performed by, the average medical students would not be likely to be of great value to the patients upon whom he practised. It therefore would seem that while stopping teeth as a means of instruction can fairly be dealt with in a general hospital, yet as a means of treatment it is almost impossible without a great increase in the number of dental surgeons at the general hospitals, for I maintain that the efficient stopping of a tooth (except in the minority of cases) requires as much skill and special knowledge as the more delicate operations in surgery. Mr. Benham will be interested to know that qualified medical men are admitted to the dental hospitals for short periods, and have thus every opportunity given them for gaining a fair amount of dental knowledge and skill. I am at a loss to understand the meaning of the phrase, "Besides, every one cannot go there;" the best answer to it would be for Mr. Benham or any medical man to pay a visit to either of the dental hospitals, when he would have an opportunity of seeing the mode and the manner of treatment of patients.

I have trespassed too much on your space, so I will only add that the attendance at hospitals of patients who are well able to pay a small fee to young and not very busy practitioners is of too large interest and of too general application for me to dilate upon.

I am, Sir, yours truly,

S. J. HUTCHINSON,
Dental Surgeon to University College Hospital.

London, Oct. 11th, 1884.

"A NEW FORM OF SUTURE."

To the Editor of THE LANCET.

SIR,—I enclose you a suture very similar to that described in your issue of September 27th by Dr. James MacMunn, but after many trials I discarded it and returned to the ligature. It appears to me that the old-fashioned needle and thread has so many good qualities to recommend it that it will require all the force of some very startling and efficient novelty to dislodge it from its present position. "The suture is objectionable" in many respects, according to Dr. MacMunn; but, after all, many of the objections mentioned by him may be actually overcome by skilful manipulation. "The approximation of the walls of a wound" can generally be secured by a wide and deep insertion of the threads, assisted if necessary by the introduction of intermediate and superficial stitches. "The circular constrictions of the skin which lead to ulceration and strangulation of the enclosed tissues" surely result from tying the ligatures too tightly, and from straining the parts into contact with each other; therefore all the responsibility of inefficiency must be thrown, not upon the sutures, but rather upon the clumsy fingers by which they were introduced. The skilful closing of a wound, moreover, demands expeditious manipulation on the part of the surgeon, but the new form of suture, from Dr. MacMunn's description of the method of using it, yields very little promise in this direction, if it requires to be held by "a thread or a piece of cork fastened to it." One word in conclusion with reference to the introduction of sutures after operations involving free incision of the skin. It is my practice to use frequently in these cases the continuous suture, and I believe this ancient mode of approximating the edges has been recently revived by many eminent surgeons. For the application of this method I am desirous of suggesting a trial of the "surgical needle and thread" which was introduced to the notice of the profession through the columns of THE LANCET some months since. The continuity of the needle and the ligature much facilitates the introduction of the thread, at the same time it ensures a new and clean needle with a perfect point for every operation. When the thread is in position, by gently drawing apart the ends of the wire the edges of the wound are evenly brought into contact, and if necessary, the apposition can be improved by a touch here and there with the point of the forceps. The continuous suture possesses another advantage as it admits of very easy removal, and surely this is worthy of consideration, for the "taking out" of the thread is often a more painful proceeding than the introduction.

I am, Sir, yours faithfully,

J. WARD COUSINS, M.D. Lond., F.R.C.S.,
Surgeon to the Royal Portsmouth Hospital.

Oct. 6th, 1884.

"THE EXAMINATION OF SURGEONS-MAJOR."

To the Editor of THE LANCET.

SIR,—Will you kindly afford me space in your columns to thank Mr. Wheeler for the amusement he has again afforded an "innocuous imbecile" by his letter. I should be sorry to give him the great trouble to "reduce his phraseology commensurate with my capacity," and have therefore elected to remain an "unknown quantity." If I acted otherwise it seems probable that Mr. Wheeler might subject me to an examination, when I fear that in his present frame of mind even his magnanimity would not save me from being plucked. I desire therefore to retire from this correspondence with as much grace as a bird can do of the genus to which so distinguished an ornithologist has decided that I belong.

I am, Sir, yours obediently,

X. Y. Z.

Oct. 22nd, 1884.

MANCHESTER.

(*From our own Correspondent.*)

OWENS COLLEGE.

THE opening of the session 1884–85 at Owens College was inaugurated on the 8th inst. by an introductory lecture by Professor Wilkins on the "Rise of Latin Literature." For some years past the special "introductory" to the medical department has been discontinued, one lecture only serving for the whole of the departments of the College. The Dean of the Medical School, Dr. Gamgee, presented his report for the past year, and in doing so alluded to the fact of this being his last appearance in his official character as dean, he having resigned that office after a tenure of nine years, being succeeded by Dr. Morrison Watson, professor of anatomy. From his report it appears that the number of medical students attending the College during the past session was 304. Three students have taken at the London University the degree of M.D., six that of M.B., and two that of B.S. Three gold medals have been gained at these examinations. The Victoria University does not at present appear to attract so many of our students as the London, four only having passed the intermediate examination in medicine of the former against eight in that of the latter, and at the preliminary scientific of the Victoria University six passed against fourteen at the London preliminary scientific; but in the course of another year these numbers will in all probability be somewhat different. The total number of entries of medical students at the College for the present session is eighty-one. The chief changes in the medical department are (1) the appointment of a number of clinical lecturers at various hospitals which have hitherto had no official connexion with the College; and (2) the establishment of a dental department, dental students having up to the present been unable to obtain a complete course of instruction in Manchester, such as is required by the licensing authorities.

THE TYPHUS FEVER EPIDEMIC.

The outbreak of typhus reported in your issue of the 4th has not assumed any large proportions, thanks to timely precautions being taken, not more than about twenty cases in all having occurred; but it has led to a little unpleasant friction between the Chorlton guardians, to whose notice the cases appear first to have come, and the health authorities of the corporation; and as a further complication, some difference of opinion arose as to whose duty it was to replace certain infected bedding that had been destroyed by the health authorities, they asserting that the patients were

Digitized by Google

paupers, which the guardians denied on the ground that the family was not in receipt of any relief from them until the outbreak of the disease in the house. Peace has, however, been made by the corporation undertaking to replace the destroyed articles.

THE NORTH-WESTERN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.

At the last meeting here of this Association a discussion took place on a paper by Mr. Vacher on "Prospective Local Government Legislation, and its Bearing upon the Work of Medical Officers of Health." To those who have paid attention to the sanitary work of this country and the ways and means by which it is carried on, or often not carried on, the conviction must be daily more and more confirmed that before sanitation is placed on a thoroughly satisfactory basis it will have to be made a matter of imperial concern, and not left to the caprice and whims of irresponsible local bodies. But recently here the newspapers have published communications from the city auditor, who, because the Health Department is a necessarily somewhat costly one, accuses it of all sorts of extravagance and mismanagement, styling it the "octopus of the corporation," and asserting that "the institution of this department was the greatest bungle that ever the council was guilty of." Again, at the neighbouring borough of Preston, at the last meeting of the town council one of the aldermen, referring to the monthly report of the energetic medical officer of health, and his inability to understand it, stated as his opinion that "they need not have that sort of nonsense printed month after month." And recently in the same town some two tons of fruit that had been seized and condemned were allowed by the magistrates in greater part to be sold after hearing the evidence of a member of the town council to the effect that "it was not meant for food, but for making pies."

FOUL-SMELLING WATER.

The cause of the bad odour of the water, which gave rise to so much complaint a few weeks since, has been discovered by the city analyst, and is rather an unusual one in potable water. He found that in those reservoirs which supplied the water complained of there was an unusual quantity of the small pond snail (Limnæa), and that to the spawn especially of these snails the fishy smell of the water supplied in the summer months was due. The remedy suggested by him is the introduction to the reservoirs of a sufficient number of fish to act as scavengers, and thus keep down these objectionable denizens of the water. Steps are being taken to carry out his suggestsons.

THE SALFORD ROYAL HOSPITAL.

This hospital is about to be considerably increased in size by the addition of fifty beds to the present building, which will then provide accommodation for upwards of 100 patients. The building committee has selected the plans prepared by Mr. Lord, but their decision has not met with the unanimous approval of the medical staff, some of whom object to the arrangement of the wards, and especially to the position of the operating theatre. Mr. Lord was until recently a member of the hospital committee.

OVER-PRESSURE IN SCHOOLS.

At the meeting of the Lancashire and Cheshire Branch of the British Medical Association, held last week at the Lunatic Asylum, Cheadle, the subject of "over-pressure in schools" was introduced for discussion by Dr. Barron of Southport, and led to a somewhat animated debate. The experience of several members was adduced to show that there were undoubted cases of injury the result of too severe or too prolonged school work, but the general opinion of those who had good opportunities of observation seemed to be that the amount of mischief thus produced had been, especially amongst the general public, considerably exaggerated and overrated.

THE "MEDICAL CHRONICLE."

The first number of the Manchester new medical venture appeared on the 1st inst., under the title of the *Medical Chronicle*. It is published under the authority of a committee consisting of a number of the leading members of the profession in this city and neighbourhood. It aims chiefly at giving a *résumé* of current medical work and literature, a comparatively small proportion of its pages being occupied by original communications.

The University College of North Wales is showing much activity. Nearly £9000 has lately been subscribed in Manchester towards its funds. Between £30,000 and £40,000 is now promised towards the £50,000 required for its endowment.

The degrees of the Victoria University, with the exception of those in medicine, are open to both sexes, and four scholarships to women have just been awarded, such scholarships being held on the condition that the holders pursue their studies at the Owens College with a view to proceeding to graduate in the University.

GLASGOW.

(From our own Correspondent.)

CHANCELLORSHIP OF THE UNIVERSITY.

FOR this office, left vacant by the death of the late Duke of Buccleuch, the names of several candidates are already mentioned. Amongst these are the Earl of Stair (who has accepted nomination) and Lord Rosebery; the Duke of Argyll also was brought forward in a letter published in the *Glasgow Herald* by Dr. George H. B. Macleod, but is disqualified by his holding a similar office in the University of St. Andrews. The Marquis of Bute, a most beneficent supporter of Glasgow University, has been suggested as a possible candidate, but probably religious prejudices are too strong in Scotland to permit of a Roman Catholic candidate being put up with any chance of success.

THE ENTERIC EPIDEMIC.

There is practical agreement among all who are qualified to judge that Dr. Russell, in his report on this outbreak, has traced the disease to its true source—namely, to a contaminated milk-supply. The chairman of the Royal Infirmary House Committee, however, assures us that the suspected milk, that from Kilwinning, can have nothing to do with the occurrence of the disease in his institution, as none of it reaches the infirmary; and he states that there are a great many things to which enteric fever might be attributed, such as "thin clothing and the rapid changes of temperature which they had lately experienced!" Unfortunately this matter has reached the stage of newspaper discussion, which has taken a somewhat offensive form.

Dr. Macewen, of the Royal Infirmary, excised the pyloric end of the stomach a short time ago for malignant disease, but the patient died in a few hours.

The Dunoon Seaside Homes seem to be progressing. At their fifteenth annual meeting it was reported that "up to the present time 26,668 had been received into the Homes, and the largest proportion of them were restored to health and strength." Financially the position of the institution is good.

PARIS.

(From our own Correspondent.)

THE FACULTY OF MEDICINE.

THE winter session of the Faculty of Medicine began on November 3rd, and the professorial staff is composed as follows:—Medical Physics, Prof. Gavarret; Medical Pathology, Prof. Peter; Anatomy, Prof. Sappey; Medical Chemistry, Prof. Gautier; Surgical Pathology, Prof. Lannelongue; Operative Surgery, Prof. Duplay; Histology, Prof. Ranvier; Morbid Anatomy, Prof. Cornil; History of Medicine and of Surgery, Prof. Laboulbène; Medical Jurisprudence, Prof. Brouardel; Clinical Medicine at the Hôtel Dieu, Prof. Germain Sée; Clinical Medicine at La Charité, Prof. Hardy; Clinical Medicine at the Necker Hospital, Prof. Potain; Clinical Medicine at La Pitié, Prof. Jaccoud; Mental Pathology at the Sainte-Anne Asylum, Prof. Ball; Clinical Diseases of Children at the Enfants-Assistés, Prof. Joffroy; Syphilitic and Cutaneous Affections at the Hôpital Saint-Louis, Prof. Fournier; Clinical Diseases of the Nervous System at the Salpêtrière Asylum, Prof. Charcot; Clinical Surgery at the Hôtel Dieu, Prof. Richet; Clinical Surgery at La Pitié, Prof. Verneuil; Clinical Surgery at La Charité, Prof. Trélat; Clinical Surgery at the Necker Hospital, Prof. Le Fort; Ophthalmology at the Hôtel Dieu, Prof. Panas; Clinical Obstetrics at the Clinic of the Faculty, Prof. Pajot.

THE ADMISSION OF FEMALE STUDENTS AS INTERNES.

The question of admitting female medical students as internes in the hospitals, in common with their male fellow-students, has been submitted to the Minister of Public Instruction, but for obvious reasons the proposition is not looked upon with much favour.

ACCIDENT TO DR. WORMS.

Dr. Worms, Physician to the Prefecture of the Seine and to the Northern Railway Company, lately met with an accident while about to take the train to Versailles. Being attached to the station, he was allowed to go about freely, and in crossing the rail at the time the employés were arranging the carriages he was caught between two of them, and narrowly escaped being crushed. He, however, had his arm broken; but Dr. Labbé, who is attending him, stated in his bulletin that the fracture was not of a serious nature, and, according to the last report, the patient is doing as well as possible.

BLOOD-POISONING FOLLOWING HUMAN BITES.

The following cases illustrate the danger sometimes attending the infliction of human bites. A lad of eighteen, employed as a waiter at a public-house, was guilty of some misdemeanor, and while his employer was remonstrating with him the lad, fearing a thrashing, took hold of the right hand of his master and bit him severely on the thumb. The publican dismissed the lad on the spot, had his thumb dressed, and thought no more about the matter, when a few days ago—that is, about two months after the bite—phlegmonous inflammation set in, and the patient was carried off in a few hours, death, according to the medical attendant, having been caused by blood-poisoning. In a recent quarrel between two newspaper editors in Paris one bit the hand of the other, soon after which lymphangitis set in in the arm of the wounded patient, which was accompanied by symptoms of erysipelas, from which, however, he soon recovered.

Paris, Oct. 21st.

INDIA.

(*From a Correspondent.*)

THE INDIAN CHOLERA COMMISSION.

AT a special meeting of the Grant Medical College, Bombay, on Sept. 20th, the members of the Indian Cholera Commission—Drs. Klein, Gibbes, and Lingard—gave a demonstration of certain micro-organisms found in disease, and exhibited the following microscopical specimens:—(1) The bacillus of malignant anthrax; (2) a specimen from an artificial cultivation of the bacillus anthracis; (3) micrococci found in septicæmia produced in a mouse by inoculating human sputum from a case of croupous pneumonia; (4) the bacilli of swine fever; (5) organisms found in a case of noma in a calf; (6) tubercle bacilli; (7) typhoid bacilli; and (8) specimens of the large varieties of spirilla and vibriones.

CHOLERA EXPERIMENTS IN THE HUMAN SUBJECT.

It appears from the local papers that a suggestion is made in Bombay that the question of the infectiveness of the cholera microbe should be put to practical test in the human subject in the case of convicts sentenced to death. In the event of the result being *nil*, the sentence should be commuted, the subjects for such experiment being given the choice between the risks of taking cholera and the hangman's rope.

HONORARY HOSPITAL SURGEON IN BOMBAY.

The Government of Bombay has, in a resolution, expressed its opinion that the experiment of working a hospital by the gratuitous services of honorary assistant-surgeons has, *de facto*, proved to be a failure. On the recommendation of the Surgeon-General, it seems, the Government proposed to the Municipality that instead of these honorary assistant-surgeons in future a junior commissioned surgeon of the Indian Medical Service should be appointed, at a salary of from five to six hundred rupees per mensem. When this Governmental resolution came before the Town Council, Dr. Blanc, a member, took occasion to point out that the experiment that had been under trial and had not succeeded was far from being really based, as is generally supposed by the laity, upon the system in vogue at home. In England the honorary hospital staff are not paid a salary for hospital services, but they always hold lectureships, which usually carry with them fair remuneration. In the case of Bombay matters differed *toto cœlo*. The men are young, and they have to live; their prime care is not the hospital, but their dispensaries (open surgeries or medicine shops) in private practice which gives them their livelihood. It is to be hoped that the recommendation of the Surgeon-General with the Government of Bombay will be acted upon, and a member of the Indian Medical Service be posted to the Goculdas Tejpál Hospital (which is a native general hospital), as is done in the case of the European General Hospital.

THE FELLOWS OF THE ROYAL COLLEGE OF SURGEONS.

AT a meeting of the Committee of the Association of Fellows of the Royal College of Surgeons of England, held on Thursday, the 23rd inst., the report of the scheme of reform of the College prepared by the sub-committee was discussed, and, with slight modifications, approved and adopted. This report, the chief points of which we hope to publish next week, will be printed and circulated amongst the members of the Association with a view to its discussion at a general meeting, to be held at the Medical Society's rooms on Saturday, November 8th. The committee passed a resolution condemning the action of the Council of the College in entering into a combination with the Royal College of Physicians to hold a joint examination, without the direct knowledge, sanction, and approval of the Fellows and Members of the College.

THE SERVICES.

WAR OFFICE.—The Secretary of State for War has appointed Howard W. Hunt, Esq., M.R.C.S.E., to be Assisting Visiting Surgeon for Shorncliffe, under the Contagious Diseases Acts, 1866 to 1869, vice A. Randall Davis, resigned.

MEDICAL STAFF.—Surgeon-Major Alexander Turner, M.D., is granted retired pay, with honorary rank of Brigade Surgeon.

ADMIRALTY.—Staff Surgeon Thomas D'Arcy Bromlow, M.D., has been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet. Fleet Surgeon John William Sinclair Meiklejohn, M.D., has been placed on the retired list, with permission to assume the rank and title of Deputy Inspector-General of Hospitals and Fleets. The undermentioned Surgeons have been promoted to the rank of Staff Surgeon in Her Majesty's Fleet:—William Frederick Spencer, M.D., Robert William Williams, Albert Charles Queely, Otway Peter Browne, B.A., M.D., Francis Reginald Malcolm Loftie, Alfred Hubert Kelly, B.A., M.D.

RIFLE VOLUNTEERS.—1st Cornwall (Duke of Cornwall's): Surgeon Humphry Davy, M.D., resigns his commission, also is granted the honorary rank of Surgeon-Major, and is permitted to continue to wear the uniform of the corps on his retirement.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having passed the required examination for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 20th inst.:—

Bidwell, Herbert, L.R.C.P. Lond., Ely.
Blackwood, Frederick Martindale, L.S.A., Sunderland.
Bond, Charles Knox, L.R.C.P. Lond., Lupus-street.
Bristow, William Moss, L.R.C.P. Ed., Liverpool.
Caldecott, Charles, L.S.A., Basingstoke.
Clay, Augustus Frederic, L.S.A., Birmingham.
Davies, Howard, L.S.A., Pontypridd.
Geil, John McHutchin, M.B. Glasgow, Isle of Man.
Hick, Joseph, L.R.C.P. Ed., Leeds.
Paul, Edmund William, L.S.A., Langport.
Pennington, Thomas, Hyde, near Manchester.
Rugg, George Lewis, L.S.A., Clapham-road.
Scattergood, Oliver, M.B. Oxon., Leeds.
Shackleton, Henry, M.B. Dub., Dublin.
Thomas, Benjamin Wilfred, L.R.C.P. Ed., Heathcote-street.

Digitized by Google

Admitted Members of the College on the 21st inst.:—

Alcock, Samuel King, L.S.A., Burslem, Staffs.
Barker, William James Townsend, L.S.A., Bristol.
De Montbrun, Domingo Antonio, Trinidad, West Indies.
Dobson, Arthur Edward, L.R.C.P. Ed., Downs-park-road.
Gay, John, Hampstead.
Hale, Charles Henry, L.R.C.P. Lond., Bicton, Salop.
Hartley, Horace, L.R.C.P. Ed., Camberwell.
Jackson, Richard Arthur, Oswestry.
Jordan, Gregory, M.B. Edin., York-road.
Marder, Edward Swan, Lyme Regis.
Paine, George Reuben Robins, L.S.A., Old Woolwich-road.
Piggott, Frederick Cecil Holman, L.S.A., Richmond.
Silverlock, Richard Greenhill, L.S.A., Northwell, Norfolk.
Tyler, Alfred Joseph Reeve, L.S.A., Islington.
Walker, Joseph Eagland, L.S.A., Huddersfield.
Wharry, Henry Gordon Oliphant, L.S.A., Gordon-square.
Youel, Sidney Herbert, L.R.C.P. Ed., St. John's.

Admitted Members of the College on the 22nd inst.:—

Archer, Thomas Launcelot, Clapton.
Barnard, Arthur Joynson, L.R.C.P. Ed., Buxton.
Bluett, George Mallack, Regent's-park-terrace.
Butler, Henry John, Bradford.
Counsell, Herbert Edward, Worcester.
Courteen, Raymond, Monmouth.
Currey, Robert Henry, Edge-lane, Liverpool.
Fitton, Herbert, L.R.C.P. Ed., Dewsbury.
Fox, Herbert, L.R.C.P. Lond., Croydon.
Genge, Richard Edward, L.R.C.P. Ed., Waterston, Dorset.
Greene, Edward Campbell, L.R.C.P. Lond., St. Leonards-terrace.
Jeffree, Frank, L.S.A., Clapham-park.
Kaye, Joe Nicholson, L.R.C.P. Ed., Kirkstall, Leeds.
Page, Alfred Matthew, Belsize-park-gardens.
Patrick, Joseph Henry, Birmingham.
Rhys, Watkin Llewellyn, Treherbert, South Wales.
Smith, Arthur John Nitch, L.R.C.P. Ed., Ely, Cambs.
Stewart, George Eland, Pocklington, Yorks.
St. Romaine, Richmond Edward, Calcutta.
Tanner, Charles Edward, Marlborough.
Trower, Arthur, St. Mary-at-Hill.
Walton, George Augustus Turner, Brook-street.
Weir, Frederick William, Bristol.
Wills, William Alfred, Westminster.

The following gentlemen passed the Primary Examination in Anatomy and Physiology at meetings of the Board of Examiners on the 16th, 17th, and 18th inst.:—

Harry Adams, John Jones, and Walter Malden, St. Bartholomew's Hospital; F. F. Foster-Foster, F. Arnott Collington, H. Munyard Brownfield, T. Forster Christal, and Thomas Halliwell, Guy's Hospital; H. Herbert Atter, Joinville T. Blancard, A. Percy Blenkinsop, R. Brooks Popham, and Frank Boxall, University College; Onslow A. Wickham, J. Cavendish Molson, and W. A. J. Nottingham, London Hospital; Henry R. Blee, Archibald B. Brockway, and Aymer d'Estampes de Vallancey, St. Thomas's Hospital; Charles C. Braine, Harold E. Mortis, and W. H. H. C. Davey, Charing-cross Hospital; Joseph Fayrer, St. George's Hospital; Babajt Saroottam Wankar, Bombay; Rhys Powell, King's College.

COLLEGE OF PHYSICIANS IN IRELAND.—At the October examinations the following candidates obtained the licences in Medicine and Midwifery of the College:—

MEDICINE.—Mary Emily Dowson, Switzer Soutter Harwood.
MIDWIFERY.—Robert Ball, Mary E. Dowson, Nicholas C. Ferguson, Switzer Soutter Harwood, Archibald P. B. Moore, Robert Thomas Alexander O'Callaghan.

The undermentioned have been admitted Members:—

Alexander Fry.
John J. Kenefick.
Edward D. O'Neill.
John P. Ryan.
R. H. Robinson, Sur.-Maj. A.M.D.
Henry Walter Boyd.
John Alfred Freud.
Samuel Keays, Surgeon, R.N.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Oct. 16th:—

Bennett, George Herbert, Granville-square.
Bray, Percy Dean, Bognor, Sussex.
Daniel, Ronald Angus, Cornwall-road, Bayswater.
Hood, C. John Jacomb, Broadwater House, Tunbridge Wells.
Jeffree, Frank, Howard Lodge, Atkins-road, Clapham-park.
Laurie, Caspar Robert, The Elms, Buckhurst-hill, Essex.
McCabe, W. Alexander Bowes, St. Helier's, Jersey.
Raywood, John Robert Isaac, Thoone, Doncaster.
Southern, Francis Gerald, Broad-street, Ludlow, Salop.
Voisin, Alexander Bishop, St. Lawrence, Jersey.

MR. T. MOSSE MACDONALD has been appointed Secretary to King's College Hospital.

COLLECTIONS in aid of the Dublin Hospital Sunday Fund will be held this year on November 9th.

BY command of the Queen the General Infirmary of Hull will henceforth bear the name of the Hull Royal Infirmary.

AT the quarterly meeting of the Directors of the Naval Medical Supplemental Fund, held on the 14th inst., Sir W. N. E. Stewart, K.C.B., Q.H.P., Inspector General, in the chair, the sum of £[illegible] was distributed among the several applicants.

MR. VANDERBILT has made a donation of 500,000 dollars to the College of Physicians and Surgeons in New York, to be used as a building fund.

ON Saturday last collections were made in the principal thoroughfares of Eastbourne on behalf of the Princess Alice Hospital.

THE Queen has sent a portrait of herself and one of H.R.H. the late Duchess of Kent to the Royal Hospital for Diseases of the Chest, City-road.

MR. M'DONAGH, who is in his eighty-fourth year, and has been medical officer of the Clapham district of the Wandsworth Union ever since the formation of the board, has been granted a superannuation allowance of £47 10s.

ASSISTANT COMMISSARY GENERAL J. S. YOUNG has been appointed by the National Society for Aid to the Sick and Wounded in War as the Society's agent with the expeditionary force under the command of Lord Wolseley in Egypt.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—At a meeting of the general committee, held on the 16th inst., a letter was read from Mr. Chesshire resigning his appointment as honorary surgeon, and the committee unanimously passed a resolution expressing their regret at losing the services of Mr. Chesshire, and their sense of the value of the work done by him in the hospital for the long period of [illegible] years.

A HANDSOME GIFT.—A patient of Dr. Braxton Hicks having placed a sum of money at his disposal to lay out on any good work he thought fit, Dr. Hicks has just presented his native town, Lymington, Hants, with a complete Ashford litter, with all the requisite extras; and also a quantity of nursing material to form a depôt for lending out. At the presentation a St. John Ambulance centre was formed to take charge of it; and the nursing material was placed under the care of the hon. secretaries of the already existing nursing class of the association.

TESTIMONIAL TO DR. J. NORTHCOTE VINEN.—At the last meeting of the Society of Medical Officers of Health, Dr. J. Northcote Vinen, who has for twenty-one years held the office of honorary secretary to the Society, was presented with a testimonial on his resignation. The testimonial bears witness to "the long and valuable services which Dr. Vinen has devoted for a period of more than twenty years, with manifest advantage to the interests of the Society. But Dr. Vinen's services have not been confined to the Society only. As its honorary secretary, his efforts have not been less beneficial to the community at large, and to which besides its members will join in "sincere good wishes for future welfare and prosperity."

COLLEGE OF PHYSICIANS IN IRELAND.—On St. Luke's Day, the 18th inst., the following office-bearers were elected for the ensuing year:—President: F. R. Cruise. Vice-President: George F. Duffey. Censors: G. F. Duffey, J. M. Purser, F. J. B. Quinlan, J. R. Kirkpatrick. Additional Examiners: J. Magee Finny, A. Foot, A. Nixon, J. M. Purser, F. B. Quinlan, W. G. Smith. Examiners in Midwifery: Stephen McSwiney, W. Smyly. Professor of Medical Jurisprudence: W. Travers. Representative on the General Medical Council: A. Smith. Registrar: J. Wm. Moore. Treasurer: A. Smith. Examiners for the Certificates in Sanitary Science: Drs. Duffey, Smith, and Quinlan, with Messrs. Price and Parry. Librarian: Samuel W. Wilson. At the same meeting John M. Redmond was elected a Fellow of the College.

Medical Appointments.

Intimations for this column must be sent DIRECT to the OFFICE OF THE LANCET before 9 o'clock on Thursday Morning at the latest.

AITCHISON, HENRY HYSLOP, M.B., L.R.C.P. Ed., has been appointed Medical Officer for the Wallsend District of the Tynemouth Union, vice J. Aitchison.

APPLEFORD, S. HERBERT, M.R.C.S., L.R.C.P. Lond., has been appointed Surgeon to the Eastern Dispensary, vice James [illegible] resigned.

BARBER, FREDERIC S., M.R.C.S., has been appointed [illegible] to the Kidderminster Infirmary, vice [illegible] resigned.

BERRIDGE, J. J., F.C.S., has been appointed Public Analyst to the Borough of Falmouth.

CALEB, CLEMENT C., M.B., M.R.C.S., has been appointed [illegible] to the North London Hospital for Consumption and Diseases of the Chest, Hampstead.

Digitized by Google

CHILTON, MAURICE ALFRED, L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Resident Medical Officer to the Wellington Hospital, New Zealand.

CUTHBERT, WILLIAM THOMAS, L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer to the Ravenswood Hospital, Queensland.

EVANS, E., B.A.Cantab., has been appointed Demonstrator of Physiology at St. Mary's Hospital Medical School, Paddington, vice Dr. Nall, resigned.

JAYNES, VICTOR A., M.R.C.S., L.S.A.Lond., has been appointed Public Vaccinator for Bermondsey, vice Cuolahan, deceased.

LAWRIE, MACPHERSON, M.D., has been appointed Physician and Gynecologist to the Sanatorium, Weymouth.

MORRIS, DAVID WILLIAM, L.K.Q.C.P.I., M.R.C.S., has been appointed Medical Officer for the Third District of the Dursley Union, vice Connellan.

SHACKLETON, EDMUND, L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer and Public Vaccinator for the South Norwood District, Croydon Union, vice W. Milligan, M.R.C.S., L.R.C.P.Ed., resigned.

SHAW, H. C. COSTELLO, M.R.C.S., L.R.C.P.Lond., has been appointed Resident Medical Officer to the Richmond Hospital, Surrey, vice A. L. Copner, resigned.

SMAILES, THOMAS, L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for the Honley District of the Huddersfield Union, vice Dyson.

TENNANT, CHARLES, M.R.C.S., has been appointed Medical Officer for the Houghton-le-Spring District of the Houghton-le-Spring Union, vice Lyon.

WEBB, MALCOLM, M.B Lond., M.R.C.S., has been appointed Resident Medical Officer to the Royal Infirmary, Manchester, vice David Grant, M.B.Ed., resigned.

WILSON, JOHN SMITH, L.R.C.P.Ed., M.R.C.S., has been appointed Government Medical Officer and Vaccinator for the Walgett District, New South Wales.

Births, Marriages, and Deaths.

BIRTHS.

DUKE.—On the 13th ult., at Quetta, the wife of Surgeon-Major O. T. Duke, Political Agent, Kelat, prematurely, of a son.

HILLIARD — On the 21st inst., at Aylesbury, the wife of R. Harvey Hilliard, M.D., of a daughter.

HOUGH.—On the 18th inst., at Full-street, Derby, the wife of C. H. Hough, of a daughter.

MARSHALL.—On the 17th inst., at Nottingham, the wife of Lewis W. Marshall, M.D., of a daughter.

MARRIAGES.

BALL—COLES.—On the 16th inst., at St. James's, Exeter, William Montague Ball, M.B., of Hounslow, to Marion, daughter of the late Thomas Darnford Coles, of Castle Cary, Somerset.

HACON—CAMPBELL.—On the 1st ult., at St. Paul's Cathedral, Wellington, New Zealand, by the Ven. Archdeacon Thorpe, Walter Edward Hacon, L.R.C.P.Lond., Resident Medical Superintendent of the Hospital for the Insane, Sunnyside, Christchurch, N.Z., to Margaret Jane, daughter of A. de Grand Campbell of Wellington.

HOPE—WEBER.—On the 15th inst., at St. Margaret's Church, Whalley Range, Manchester, William Hope, M.D., of Curzon-street, London, to Adèle, daughter of the late L. F. Weber, Esq., of Timperly, Cheshire.

LAURIE—MACLEOD.—On the 15th inst., at Melville-street, Edinburgh, William L Laurie, M.D., of Drumniel, Appin, Argyleshire, N.B., to Jessie, youngest daughter of the late Rev. Norman Macleod, Free Church Minister, North Uist.

NEALE—CRISP.—On the 21st inst., by the Rev. Canon Duckworth, D.D., William Henry Neale, M.D.Lond., B.S., F.R.G.S., 24, Loudoun-road, N.W., second son of Dr. Richard Neale to Alicia Eyre, fourth daughter of the late Artie Crisp, of 86, Boundary-road, N.W.

PIRRIE—TYTLER.—On the 16th inst., at Victoria-street, Aberdeen, James Miller Gordon Pirrie, M.D., of Aberdeen, to Mary Penelope, youngest daughter of the late R. B. Tytler, Esq., of Ceylon.

DEATHS.

BARHAM.—On the 20th inst., at Truro, Charles Barham, M.D.Cantab., aged 80.

CHAVASSE.—On the 19th inst., at Wylde-green House, Wylde-green, near Birmingham, Thomas Chavasse, F.R.C.S., aged 84.

GEOGHEHAN.—On July 21st, at Sydney Arthur F. Geoghehan, M.B., M.Ch.Dub., aged 23.

MERCER.—On the 15th ult., at Equira, West Coast Africa, Adolphus Richards Mercer, M.R.C.S., youngest son of the late Thomas Mercer, Watton, Herts, aged 38.

PEARCE.—On the 5th inst., at Holsworthy, North Devon, Edward Thomas Pearce, Surgeon, aged 40 years.

RABBETH.—On the 20th inst., at the Royal Free Hospital, Gray's-inn-road, Samuel Rabbeth, M.B.Lond., M.R.C.S., &c. &c., of diphtheria, caught from a child whom he was attending professionally, and whose life he made a noble effort to save by an act that was certain to place his own in extreme danger, aged 26. The funeral will take place at Barnes Cemetery on Monday, at 2 P.M.

SCOTT.—On the 21st inst., at St. Leonards-on-Sea, Andrew James Scott, M.D., late Madras Medical Service, aged 67 years.

WORRALL.—On the 10th inst., after an operation for neuralgia, John Charles Worrall, M.R.C.S., L.S.A., of Overndale House, near Bristol, eldest son of the late Captain Worrall, R.N., of Pownall Hall, Cheshire, aged 79.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

THE RELIGIOUS PRESS AND "QUACK" ADVERTISEMENTS.

THE "quack" advertisements which are circulated by professedly Christian journals are among the offences which cause intelligent and reverent men to doubt. A specimen of such advertisements is sent to us (from a religious journal having a very wide circulation), abusing the medical faculty and vaccination, and extolling the "Anti-vaccination Mixture." The whole thing is so absurd that we are almost ashamed to notice it, excepting to regret that a well-meaning contemporary should permit such rubbish to appear even in its advertisement columns.

Mr. J. W. Philip.—The facts are very interesting. But facts are quite thrown away on anti-vaccinationists.

"AN APPEAL TO PUBLIC VACCINATORS."

To the Editor of THE LANCET.

SIR,—I beg to thank those gentlemen who were kind enough to answer my appeal in your journal, some of whose letters give interesting facts relating how the writers commenced their work by making six vesicles, but in self-defence were compelled to reduce the number to four in order to compete with qualified (!) men who advertise to vaccinate only in one or two places, or because of threats held out to them by those who did not approve of their mode. I have heard of men vaccinating children and giving a certificate the same day, without waiting to see whether the operation had proved successful; but I little thought there were any who increased their charges on the sole condition of reducing the number of vesicles. A vaccination officer of a large district tells me that he occasionally finds children of whom he has received successful certificates with such results of the operation that neither he nor the mother can tell on which arm it was performed. Of the twenty-two answers I have received one public vaccinator makes 2 vesicles "of good size," one makes 2 the size of a threepenny-piece, six make 4 and four make 5 the sizes of which are not given, one makes 3 the size of a sixpence, two make 4 the size of a threepenny-piece, one makes 4 of half an inch in diameter, two make 4 of three-eighths of an inch in diameter, one makes 4 or 5 of a quarter of an inch in diameter, one makes 6 of five-sixteenths of an inch in diameter, one makes 3 on each arm, and one considers his scarifications are equal to 6 or 8 vesicles. As the large majority seem only to make four marks, I must conclude that they are right, and that I am over-zealous in producing more than that number, and suppose I must be more moderate in future. With such a range of numbers and sizes it seems to me that some of us must be doing superfluous work, or others are hardly coming up to the mark. Surely, we can decide upon some standard of size and number, and avoid the remarks of mothers about Dr. So-and-so's places being so much smaller or fewer, bearing in mind, however, the result of Dr. Marson's observations—the greater the number of marks, the less the mortality from small-pox.

I am, Sir, yours truly,

Walthamstow, Oct. 20th, 1884. THOS. SCORESBY-JACKSON, M.D.

AN ASTOUNDING CIRCULAR.

A DISTINGUISHED member of the profession has received the following circular, which we publish in full.

"DEAR SIR,—We enclose card of a wine we are advertising extensively, and shall be glad to know if you would allow us to send you a sample of it for purpose of analysis, and to obtain your certificate. We are willing to pay any reasonable fee for same. Kindly reply early as convenient, and oblige yours truly, "JAMES GREEN AND CO.
"Castle-street, Dublin, and London."

It is to be hoped that all medical men to whom the attractive combination of advertisement, sample, and fees is presented will intimate to the senders their sense of insult and injury.

Dr. F. E. Pearse.—1. A Poor-law medical officer is not bound to attend upon an overseer's order, unless it is marked "urgent," or unless by special contract made with the guardians.—2. A coroner has nothing to do with making orders to Poor-law medical officers. Of course, he can give his own opinion on the matter at the inquest.—3. The overseer ought to have put "urgent" on the order if he considered it urgent, or have sent the messenger to the relieving officer for an order if he did not consider it urgent, unless he felt that an order could not be obtained from the relieving officer on that day or at that time of day.

Malignant Throat.—Our correspondent will find that less caustic remedies suffice—e.g., the diligent application of glycerine of borax, or of a strong solution of carbonate of soda, or the use of spray of lime-water. We have no experience of an application of sublimate and glycerine.

Omega.—For medical anatomy there is no text-book. The viscera, &c., should be read in Gray; therapeutics, Ringer or Mitchell Bruce; insanity, Blandford.

"A MODIFICATION OF DR. JUNKER'S INHALER."

To the Editor of THE LANCET.

SIR,—The makers of Dr. Junker's apparatus have done me the honour of making my paper in your issue of Oct. 4th the text for a eulogy upon their own apparatus. I crave your indulgence for space to set Messrs. Krohne and Sesemann right upon one or two points.

It is admitted that my method of refilling the reservoir is superior to theirs, always provided the stopper fits as it should—viz., firmly enough to maintain the air-tight condition, and yet not so tightly as to offer any obstruction or loss of time in its removal. Now, experience amply proves that this object is attained by my plan. Any competent observer who has used the screw top and then adopted my plan cannot fail to realise the immense superiority of the peg over the screw. I may state there is absolutely no fear of the peg being shot out, as suggested. The objection I urged, that their apparatus makes a natural bimanus into a monomanus, Messrs. Krohne and Sesemann opine, can be obviated by a little skill and practice. Undoubtedly; we are all aware what marvellous dexterity is acquired, by skill and practice for example, by the gentlemen who eke out their income by setting a dozen plates spinning on end. This is wonderful; but is it useful? My contention is that although I presume anyone accustomed to administer anæsthetics with Dr. Junker's apparatus does habitually perform the feat of compressing the bellows, steadying the face-piece, and feeling the maxillary (or, as I should suggest, the facial pulse); yet it is a useless expenditure of energy when so simple a method as mine obviates the necessity. It is, I believe, a wise saying that a man cannot do more than one thing *well* at the same time. When a life hangs in the balance it is certainly right to have at disposal the full complement of hands with which nature has gifted us. Passing to the question of the face-piece, I beg to dissent from the statement that a rigid vulcanite face-piece, even when supplemented by the handkerchief, "does away with the necessity of a series of face-pieces." This is not so in my experience, as the nose-arch is with a thin, emaciated face a source of great trouble, even when held lightly. Patients certainly prefer the soft leather face piece, and I find it quite as easy to allow them to breathe with comfort when using it as when employing the rigid face-piece. "Junker's inhaler appears to be misunderstood by many." The connexion of this statement is hard to find; nor does it appear to me to be strictly accurate. Dr. Junker himself very lucidly described and explained his apparatus, and Messrs. Krohne and Sesemann have more than once been at the pains of further elucidating the matter in the public press. These accounts he who runs may read. I cannot agree to the statement that the face-piece should not fit the face and needs no accurate co-adaptation. A long experience with the mode of applying the face-piece convinces me that when a gentle stream of air is passed through the reservoir it answers far better to have a closely fitting face-piece.

In conclusion, I would beg to state that my motive for giving publicity to my own instrument was simply to give those interested in the matter a chance of employing a method which has in my hands proved more serviceable than Dr. Junker's. Each practitioner will use his own judgment, and that instrument which seems best in his eyes. It matters very little under whose name the apparatus is known. I regard the modifications I suggested as slight enough in themselves; but I must be pardoned for thinking the *tout ensemble* as infinitely more convenient than the arrangement usually sold by Messrs. Krohne and Sesemann. I am, Sir, your obedient servant,

Gower-street, Oct. 20th, 1884. DUDLEY W. BUXTON, M.D.

THE EMPLOYMENT OF CHILDREN IN FRANCE.

IN accordance with the law of 1874 which provides for the inspection of all industrial establishments in France where young children are employed, 47,317 shops and factories were visited during last year, of which 24,756 were in Paris. The total number of children of both sexes who came under the inspectors' notice was 213,101, of which Paris contributed 39,484. The legal age for children to commence work is after the completion of the twelfth year, though in certain industries they are permitted to enter the shops two years earlier. Twelve hours a day is the permissible term of labour, and all night work is forbidden. No child under twelve years of age can be employed without a certificate that he or she is sent to school, public or private. Between twelve and fifteen, unless they have a primary elementary certificate, children can only work six hours a day, and are obliged to go to school during the other half. The average number of children having the school certificate between twelve and fifteen years was 69 per cent. in 1883, and of the Parisian contingent the average is 60 per cent. The number of accidents which happened to children last year was 175, of which Paris was responsible for forty-two.

R. D.—The fee in the case mentioned would be £2, according to Art. 183. Foot-note No. 2 to this article in Lumley's Manual runs thus:—"Where delivery of the child had taken place but the placenta was retained, and the umbilical cord having been ruptured the patient's life was in danger, the case was considered to be within this Art. 183."

REGISTRATION OF BIRTH.

To the Editor of THE LANCET.

SIR,—Will you kindly give me your opinion of the following case your next issue.

A young married woman while on a visit to her parents was prematurely confined. The mother and child both did well, and as soon as possible returned home, to H——, nearly fifty miles, without registering the birth of the child. At H—— the registrar said he was unable to register, saying it must be done where the birth occurred. The mother, accordingly wrote to her parents to that effect, and her father went to the registrar, who, however, refused to register without the presence of one of the parents of the child, and compelled the mother to travel all the way from H—— for that purpose. Was this absolutely necessary? I am, Sir, yours truly,

Oct. 14th, 1884. G. S.

*** It appears from the statement of facts in our correspondent's letter that the local registrars of births and deaths were but imperfectly acquainted with their duties, as it was certainly unnecessary for the mother to travel *fifty* miles to register the birth of her child. The registrar of the place where the child was born should, under the circumstances, have accepted the information of the grandfather and occupier of the house in which the birth took place; or the registrar of the place where the mother resided should have taken the information of the birth from one of the parents, in the manner provided by the Births and Deaths Registration Act of 1874, and forwarded it to the registrar of the place where the birth took place, to be inserted in his birth register. The facts should be reported to the Registrar-General, at Somerset House, London, in order to prevent such blunders in future.—ED. L.

"WIDTH OF STREETS."

To the Editor of THE LANCET.

SIR,—In your last issue appeared a short article under the above heading. I desire to call your attention to the way in which streets are being narrowed in London. Many of our broad thoroughfares, such as Euston-road, Cambridge-road, and Kennington-road, were originally built in long terraces of residential houses, with gardens in front of them, at the bottom of which our fathers planted trees that have now grown up to afford a grateful shade to the passers-by. These gardens are rapidly disappearing. The trees are first cut down, and shops are built out in front of the houses. After a few years the shops are improved (?) and houses of several storeys are erected in their places. The streets are thus narrowed, the traffic is congested, and the air stagnates in the deep and narrow streets. Surely, the local authorities of the Board of Works might make an effort to preserve these fine thoroughfares at their original width. If when shops were necessitated by the spread of the metropolis they could be built on the level of the present houses, the gardens might be paved, and the trees left to form a pleasant shade between the footpath and a roadway that might be widened by the addition of the present foot pavement.

I am, Sir, yours obediently,

Margaret-street, W., Oct. 18th, 1884. HENRY B. COLLINS, Surgeon R.N. (retired).

Bursitis Bursæ Patellæ.—The easiest mode of settling the question would be to translate the terms into English. Bursitis bursæ patellæ: inflammation of a bursa, of the bursa of the patella. The phraseology certainly seems redundant; it means inflammation of the bursa of the patella.

Enquirens asks, What will be the best contrivance to get for a patient whose two arms he has amputated an inch and a half above the elbow-joint.

Digitized by Google

M.—We see nothing to object to in the statements conveyed in the circular; and so long as it was addressed only to the class it was intended for, we think the medical officer was justified in issuing it. During periods when epidemics are rife it is only right and proper that those responsible for the health and well-being of large bodies of men should issue plain and comprehensive instructions to those under their own immediate care. The procedure only becomes doubtful when such circulars are addressed to the public at large without the co-operation of the other medical men of the district.

Mr. W. Waterfield.—The melancholy occurrence, which we notice elsewhere, will no doubt give rise to many suggestions with a view to obviate the need of resorting to the procedure which had in the case referred to so lamentable a result. But mechanical means for clearing a tracheotomy tube have hitherto been found to be unavailing, chiefly because the danger to life being sudden and imminent, the instrument is rarely at hand for immediate use.

J. P.—See reply above.

"RIDING v. DRIVING."

To the Editor of THE LANCET.

SIR,—In answer to the correspondent who wrote on the above subject in your last issue I beg to submit my experience.

If expedition is considered, preference must be given to driving. I quite agree with your correspondent that cobs about fourteen hands are more useful than larger animals; they are sufficiently strong for heavy roads in winter. There is no doubt that the legs of Welsh cobs, with quality, suffer less from regular work on hard roads than do those of English horses. If speed is not a first consideration, and if in addition the roads are rough, it seems that considerable advantages are to be derived from riding, foremost among which I would place the exercise riding affords. Speaking generally, it is probably more convenient and less expensive for a man not above middle weight to drive most in summer, when the roads are hard, and ride most in winter. The disadvantages of riding on ordinary visiting rounds consist of mounting and dismounting, compared to stepping in and out of a trap, and the necessity of leaving the horse in charge of a stranger during the visit. For night work I believe riding is safer than driving, as the most common risk, especially during dark nights, arises from coming into collision with vehicles; and as it is probable that a horse can see very much better than his rider in darkness, the risks of collision are lessened by riding, as most horses will not go too close when passing other vehicles. I fail to see any reason why your correspondent should not again get used to the saddle, for many men aged upwards of eighty ride, and even follow the hounds.—Yours faithfully,

Oct. 21st, 1884. A PRACTITIONER OF TEN YEARS' STANDING.

To the Editor of THE LANCET.

SIR,—I feel I have some claim to offer an opinion on the relative merits of riding and driving, seeing that during the last seventeen years I have had an extensive practice in a hilly district, with execrable roads, in Devon, and have given the saddle, as well as two- and four-wheel carriages, a fair trial.

To a good horseman of light weight, who can afford a really well-bred, shapely hack, there is no more agreeable, safe, and speedy mode of accomplishing a long professional round, by night or day, than in the saddle, provided, of course, the animal is sufficiently quiet to be trusted for short periods to the care of a woman, or even child, or fastened to a gate. Although middle-aged, I am quite capable of riding a spirited horse a long journey, and am thankful to say that, so far, I have had no experience of any kind of covered carriage. I vary my rounds by occasionally driving myself in a light dog-cart; but I never use the same horse in saddle and harness. In wet weather a carriage may perhaps be the more comfortable, but in cold weather I much prefer the pig-skin. A four-wheel is safer than a two-wheel carriage, but more costly in itself, as well as in its horsing. When called up at night I disturb no one in my house, but saddle and bridle my horse myself, and am thus to some extent independent of the men who object to live with doctors on account of night work. I am, Sir, yours truly,

Devon, Oct. 20th, 1884. F. M.

SHIP SURGEONS.

To the Editor of THE LANCET.

SIR,—I have been sailing in one of the Transatlantic liners for some time past, and on the last voyage heavy weather was encountered. On my being called to see a lady, a second-cabin passenger, I found her suffering from subacute rheumatism. On putting my hand on the bed I found it as damp as if it had been dipped in the sea, in consequence of a leak in the upper deck. I spoke to the captain about getting the patient removed to the first cabin, the other second cabin berths being occupied. In reply I was told that I might, if I wished, give the patient my own room, to which I rejoined that in the event of her dying, or even being taken worse, the Board of Trade would probably have something to say in the matter. Fortunately, however, the weather moderated, and the patient got well. But, to my surprise, a day or two after landing I received a note from the office informing me that my services would be no longer required. On asking the reason of my dismissal, I was informed that reasons were never given. Surely, it is time the Government took the matter up, for the protection of men who honestly do their duty. I am, Sir, yours truly,

Liverpool, Oct. 20th, 1884. L.R.C.P.

DRINK IN WORKHOUSES.

AN interesting report of the amount of "drink" consumed in the Islington workhouses is published. The average cost per head per annum is, for the workhouse and infirmary combined, 10*s.* The chief items are 231 gallons of brandy and 2752 gallons of porter. The chairman's defence of the large quantity of porter consumed was that it was given to paupers for work done in the house. We think this a bad defence. If paupers do more work than they are paid for in the board and lodging they receive, let them be paid in money, or in some other form of wages than porter. Porter may be defended as medicine, or even as diet in some cases, but as wages it is demoralising and indefensible. The brandy is chiefly consumed in the infirmary. The amount is large, but doubtless commends itself to the judgment of the intelligent medical officer, Dr. Wright.

Hygiene.—Parkes' Hygiene, Ganot's Physics, Baldwin Latham's Sanitary Engineering, and the Public Health Acts. A practical knowledge of chemistry and microscopical analysis of water is required, as well as of the manner in which a sanitary report should be written.

Dr. Harkin (Belfast).—The paper will be published shortly.

"EARTH AS A DRESSING FOR SPRAINS."

To the Editor of THE LANCET.

SIR,—The letter in your issue of Oct. 11th from Dr. Schaeffer of Baltimore, on the above subject, cannot fail to be of interest to the profession—at least, to me in opinion. I would like to know if the application of earth signifies soft clay, which may afterwards become dry, forming a more or less firm support; or dry earth, as is used in foul ulcers as a disinfectant. This dressing commends itself on the ground of being cheap and nearly always available. It would require to be added to the marine medicine chest. An accident producing sprain may occur to anyone, and at any time, and may be of almost any degree of severity. I will, however, confine my attention more particularly to that lesion referred to in the letter alluded to—viz., sprain of the ankle-joint. The most frequent cause is violent twisting, generally accompanied by rupture of some of the ligamentous fibres. The pain is very severe, and difficult to alleviate. The sufferer must, practically speaking, remain in bed, and as the march towards repair is slow, the health and temper in general suffer. My experience has not been large, nor the result satisfactory. In one case (that of a lady) recently treated I used at first a cooling lotion of chloride of ammonium with opium, ice not being available. The pain was very severe. I changed the application to a hot one, with poppy heads, as recommended by Gorham (THE LANCET, July, 1876). This was more grateful. Rest, of course, was as perfect as possible; but an attack of hysterics more or less active, extending over more than a week, exercised the joint more than I deemed beneficial. A flannel bandage could not be borne. I therefore delayed applying a plaster-of-Paris bandage (or splint) until about the end of the third week, when the patient had to leave for the Continent. She bore the journey (about 1000 miles) fairly well. She had all along complained of severe pain in the knee, which was not rheumatic. There was no swelling, and motion was not prevented. I considered this pain to be of nervous origin, in which opinion the patient's continental surgeons concurred; but they considered the pain in the ankle to be nervous also, and, removing the plaster, insisted upon the patient walking. I predict the failure of this treatment, but trust it may prove successful. The general treatment was according as the symptoms required. I regret I could not have access to the valuable works of Erichsen and Bryant, recently published. Some surgeons recommend hot applications, and others cold, while many advise bandaging (which could not be borne in this case), or a plaster splint early applied. I believe this treatment the most valuable—the form called "Bavarian," described by Esmarch, inasmuch as it provides necessary rest and permits the patient to enjoy a certain amount of exercise. It can also be more readily removed and reapplied. I would like to have some opinion on "forced locomotion" after a certain lapse of time. In a former case which I treated several months after a second accident had produced the sprain an abscess formed, but the patient died of acute phthisis. The patient in another case, which I had under observation about two years, was unable to walk. Others I have seen "laid up" for a year or more. This subject, therefore, is an interesting one to me, and I trust this letter may not encroach too freely upon your space. I am, Sir, yours truly,

Oct. 14th, 1884. BEAVER.

Mr. J. Moir.—We thank our correspondent for copies of his letter. Such letters are of great use, and tend to enlighten all who are capable of enlightenment. The immunity of the officials of small-pox hospitals obtained by revaccination might have received more attention from our correspondent. By itself, this fact is an overwhelming demonstration of the virtue of vaccination.

Student should address his queries to the respective authorities.

TRUSS FOR OBLIQUE INGUINAL HERNIA.

To the Editor of THE LANCET.

SIR,—Can any of your readers from personal experience recommend me a good truss for oblique inguinal hernia? I am very actively engaged in a large country practice, and have riding. I have tried many trusses, and all are very uncomfortable; I find the underneath strap so worrying. I am, Sir, yours truly,

Oct. 22nd, 1884. GENERAL PRACTITIONER.

Digitized by Google

ERRATA.—In our Paris correspondent's letter of last week, in the paragraph giving an account of Dr. Maurin's lecture on the etiology of cholera, in the twenty-second line from the top of the second column, instead of "$\frac{1}{1000000}$th part of iodine" read $\frac{1}{10^{6}}$th part of iodine. In line six from the end, by a typographical error, "acetious" appears for acetous. "M. Arousshon," in the first line of the last paragraph, should be M. Aronsshon.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

Clinical Lecture
ON
CHRONIC ARTICULAR DISEASE.

By RICHARD BARWELL, F.R.C.S.,
SENIOR SURGEON TO CHARING-CROSS HOSPITAL.

GENTLEMEN,—My last lecture on the subject of chronic articular disease[1] concluded with a promise that I would give you some particulars concerning the management of its two principal forms—viz., that arising in the bone and that commencing in the synovial membrane. For both of these forms I recommended some sort of splint which, while permitting free movement of other parts, should obviate all pressure and motion of the diseased joint; above all other sorts of splint I advocated one which I depicted and described. But it may happen that when the patient first comes to you the disease is already advanced, and may require some further treatment than mere rest; and under such circumstances the value of your having distinguished, by the means already indicated, the bone from the synovial malady becomes manifest.

Let us suppose that a certain portion of bone—for instance, one of the femoral condyles or one side of the tuberosity of the tibia—is enlarged, painful, and particularly sensitive to pressure; that the pain augments at night, and in the more characteristic forms of disease the limb may start violently just as the patient is falling to sleep, and the skin over the tender point of bone may be red—these symptoms indicate that the inner parts of the bone are inflamed, and that the consequent hyperæmia and effusion within the solid case produce very considerable tension; indeed, the last two symptoms show pretty clearly that suppuration is imminent or has already commenced. If this inflammatory tension, with or without suppuration, be allowed to continue, it will relieve itself in some direction, and in the vast majority of cases the inflammatory products tend towards the joint cavity. Now it is not, in my opinion, consistent with the surgeon's duty to stand aside and let such an injurious event occur; he has, indeed, the power to guide the morbid process along a safe course, and the opportunity which such power gives him should not be neglected.

As near as possible to the site of greatest tenderness and swelling he should choose a point whence he can reach the bone without opening the synovial cavity, and here, turning aside a little flap of soft parts, together with the easily detached periosteum, he may, with a small trephine-head, make an opening in the bone; or if the subject be so young that the epiphysis is still cartilaginous, he may, with a gouge rotated in the hand, remove a plug of cartilage down to the osseous nucleus. While this is being done he must observe what sort of fluid flows. If it be not pus, he must examine with a stout needle fixed in a handle or in a needle-holder to find any softened or otherwise diseased bone that may enclose an abscess cavity. Pus, when present, should be detected and eliminated. The treatment, however, is quite successful, even though suppuration have not yet occurred. I have often obtained brilliant results by the mere evacuation of serum and of other inflammatory products; for tension within a rigid cavity, such as is the bone-end, very generally results in a necrosis, or in an abscess tracking towards the joint. When therefore, either by the evacuation of pus or otherwise, you have relieved this tension, pass a drainage-tube into the osseous opening, let the part thoroughly drain, and do not allow external healing to take place until the intraosseous inflammation and discharge has subsided. The cavity must become filled up by granulation from the bottom. By this means you may save many a joint that otherwise would be doomed to destruction. But the chief object of this lecture is to direct your attention to the treatment of that sluggish synovial disease which, as I pointed out a month ago, is not tuberculous, but strumous—that is, it tends to slow, persistent heaping-up of embryonic materials; of granulation which may ultimately undergo suppurative fatty caseous, perhaps tuberculous, degeneration. Now, the problem which in each case you must solve is how to check such accumulation, how to cause the absorption of some of this inflammatory material, and conversion of the rest into fibrous tissue. Let us consider the management of like material in a situation that we can see—as, for instance, lining or filling, perhaps overfilling, an indolent ulcer, which has no tendency to heal. You treat such sluggish and exuberant granulations chiefly by two methods—by pressure and by stimulation—by which means, unless the patient be too aged and debilitated, you may heal the ulcer; in other words, you cause the hitherto intractable granulations to assume formative actions to become a fibrous tissue. Now my practice, which I strongly recommend to you, is to transfer this sort of treatment to joints.

Pressure is a most valuable resource, especially when the tumefaction is neither very large nor very soft it may without stimulation bring about the desired result. It may be applied by means of strapping the joint either with resin-plaster or with one of the many medicated plasters, such as the iodide of lead, ammoniacum and mercury plaster, &c. It may be that these preparations are of some value. But you will observe that to effect any good the pressure must be equable as well as persistent, and it is hardly possible, unless the strapping be changed often, that it should be thus continuous. I therefore prefer as a rule, and especially when the swelling is rather soft, to make pressure with a bandage of elastic webbing, which may be removed and replaced daily if necessary with perfect ease, and which keeps up more even compression. Should the swelling be large and soft, mere pressure is rarely sufficient to produce the required consolidation; the granulations must also be stimulated, and this is effected by injecting among them a solution of some slight irritant. A tubular needle, of calibre a little larger than that used for hypodermic injections, and provided with one or two lateral perforations not too near to the base, is introduced at the softest part of the swelling obliquely to the surface, so that without penetrating what joint cavity may still remain, it may traverse a considerable amount of tissue. When it is thought that sufficient fluid has been injected in one locality, the needle may be partially withdrawn without altogether removing it, and passed, of course without any fresh skin puncture, in another direction, and more may be injected. The fluid which I have found most useful, and which never in my hands has produced any but good results, is tincture of iodine, beginning with half a drachm to the ounce of distilled water, and increasing even up to two fluid drachms. The quantity to be injected must depend on the size of the child and the amount of swelling. From one to two drachms are generally sufficient, and this may be repeated in different parts of the swelling every week, or even twice a week. In the meantime pressure by the means above-indicated must be continued. Under the influence of this treatment the soft tissue soon becomes harder and begins to retract, the swelling diminishes—in fact, the sluggish granulation forms itself into fibre tissue. But you must be aware of what this formation into fibre tissue means—namely, that a certain amount of the normally flexible and mobile textures which enclose the joint cavity become stiffened and thickened, encroaching on or occupying more or less that of space, according to the amount of granulation tissue formed previous to your interference. Thus, if the malady have been treated as above so early in the case that only a thin layer of granulation had formed round and in the synovial membrane, only slight thickening will result—such thickening as is quite compatible with very good mobility—which will so increase that by some care and attention a normal state of the joint may be after a time assured. If, on the other hand, the disease has been allowed to go further—if, for instance, the joint cavity be filled, or nearly filled with granulations, which under treatment solidify into fibrous tissue, much more serious impediment to mobility must result; the bones will be conjoined by a more or less dense ligament-like material; there is false ankylosis, and if during the future course of events this tissue ossify bony union or true ankylosis occurs.

Now you will see the advantage of that which I insisted on in a former lecture—viz., placing each joint in a certain advantageous position; for instance, the elbow bent at a right angle, the knee straight, and so on; because not only are such positions those which most readily conduce to cure, but also they are such as cause the limb to be most useful to the patient should ankylosis ensue or be inevitable. I must, however, remind you that we see in this hospital a great number of cases in which a joint has become ankylosed

[1] THE LANCET, Aug. 2nd, 1884.

Digitized by Google

in a faulty position, sometimes the ankylosis is true, sometimes false, but in either case the patient is unnecessarily placed in a condition of great inconvenience, the limb being sometimes nearly useless, sometimes a positive encumbrance. In my next lecture I shall speak of modes whereby these troubles may be remedied.

A Lecture
ON
CEREBRAL HYPERÆMIA IN CONNEXION WITH TERTIARY SYPHILIS.

Delivered at the Lock Hospital, Edinburgh, July 5th, 1884,

BY P. H. MACLAREN, M.D., F.R.C.S.E.,
SURGEON IN CHARGE OF THE WARDS.

GENTLEMEN,—Primary and secondary syphilis may appear to you a somewhat limited subject for study, but within their boundaries lie some problems the solution of which will send a ray of light through all pathological science. What is the *materies morbi?* How does the morbific change become weakened and ultimately effaced by mercury? These and similar points, at all events, redeem the subjects from the charge of triviality. When your attention, however, is directed to tertiary syphilis, you are confronted with a series of phenomena so vast, so varied, and so important, that the highest cultured medical intellect has the fullest scope for the exercise of its powers. The dyscrasia which the disease has then effected produces results which may permanently disfigure, damage, or even destroy the patient. When you remember that every texture and every organ in the body may be attacked through changes taking place in the all-pervading connective tissue and the minute blood-vessels, you cannot be astonished at the fact that many diseases are closely simulated, and that several may coexist at the same time.

It was a discovery of great clinical interest which was made at the beginning of the present century that syphilis belongs to the exanthemata, is caused by the introduction into the blood of a specific poison, has a period of incubation, is followed by eruptions, and may in certain circumstances terminate naturally and favourably without the intervention of medicine. Like them, also, it may be succeeded by sequelæ. I am not prepared to say that every case of syphilis appropriately treated for a sufficient length of time will escape these formidable consequences, but from my own experience in these wards I can most positively assert that every case of tertiary syphilis which I have seen has not had specific treatment, or only for a very short time. After inoculation in a previously healthy person primary and secondary syphilis are certain and inevitable—tertiary syphilis is uncertain and occasional. But the consensus of opinion of the great authorities on this subject bears out the statement that mercurial treatment, wisely administered, minimises the risks of tertiary disease, and, conversely, that over-indulgence in alcohol by a person who has neglected the earlier phases of the disease greatly increases the chances of tertiary symptoms appearing. You are aware that the division of the subject is arbitrary, and adopted chiefly for clinical purposes.

The first two forms begin and end within a circumscribed period, with slight deviations; the last never appears until after an interval during which all secondary symptoms have ceased, usually not before the fifth year after infection. But if this be accepted as the normal period for the accession of tertiary symptoms, you must be prepared to meet with the widest variations. You have seen in these wards examples where tertiary symptoms occurred as early as the end of the second year, apparently following on without the least hiatus, and others where ten, fifteen, twenty, and even thirty years had passed before the disease reappeared in its most troublesome and most malign form. Great changes are noticeable in the quality of syphilis in the later stages. It is now no longer transmissible, its manifestations are non-symmetrical, and, instead of tending to spontaneous cure, become more permanent, and show a decided liability to recur indefinitely. Mercury has little influence over them, while iodine, on the other hand, is all powerful. When it declares itself, it does so either by a hyperæmia which is promptly followed by suppuration and ulceration, or by the deposit of a neoplasm called a gumma, which is endowed with only a moderate amount of vitality.

To-day I wish to call your attention to an example of the first form in a situation of vital importance.

Mabel L——, a girl of twenty-three years of age, contracted syphilis fully four years previous to admission into the venereal wards of the Royal Infirmary. She consulted me in April last regarding a subperiosteal abscess on either side of the lower jaw. These had opened spontaneously into the cellular tissue of the neck, causing an acute and extensive cellulitis. An incision in each submaxillary region, followed by efficient drainage, speedily effected a cure. About the middle of June she was brought to Ward 6, suffering from a severe attack of alcoholism, and when partially recovered was found to be the subject of an ano-rectal syphiloma, and remitted to Ward 20. On admission the patient lay with her back to the light in a restless torpid condition, from which she could be roused when addressed loudly, and would answer questions monosyllabically, but she never slept. She complained of pain over the left skull vertex, which was not, however, increased by tapping. She suffered from constant nausea, sickness, and slight diarrhœa. Her pulse and temperature were normal. Milk diet and an acid stomachic were ordered, and the patient was subjected for two days to the closest possible observation. During that time the symptoms remained pretty much as before, except that the temperature showed extraordinary oscillations, ranging between 101° and 105·4°; pulse 100. Five grains of quinine were administered every four hours, and an icebag applied to her head, from which the hair had been cropped close. The following day (June 20th), after three doses, the temperature became slightly subnormal, and ranged between 96° and 97·4°; pulse 92. Sickness somewhat less. Quinine stopped and icebag removed.—June 21st: Torpor and general condition *in statu quo*. Slight twitchings of both arms were observed. Speech more imperfect and laboured. Pupils widely dilated.—22nd: Twitchings during this and the two following days gradually developed into clonic spasms of both arms, which were almost continuous, and were specially marked upon the right side. The face became somewhat turgid-looking, and twitchings of the masticatory muscles were frequently observed. During this period the pulse and temperature were slightly above normal. Patient was now ordered ten grains of iodide of potash thrice daily.—25th: Throughout the next six days the symptoms modified but slightly. The pulse and temperature although showing a tendency to oscillate became more approximated to the normal. Towards the end of this period the movements of the arms were if anything less marked. Twitchings of both eyelids were however observed, and some nystagmus.—July 1st: Patient now appeared more intelligent. Heard and answered questions in a manner which showed that she was still suffering from ataxic aphasia. She still complained of pain over the left skull vertex. Spasms very marked but absent during sleep. Right arm specially affected. In addition to the clonic spasms of the lower jaw muscles, there were almost continuous shakings of the head, which, however, like the other abnormal movements, were most marked when the patient was excited under examination. Both arms showed slight paresis. Incontinence of urine was present. Ankle clonus was made out by Dr. James's method on both sides, specially the right. Pulse 90 to 100 and irregular. Temperature about 100° generally. Sickness and anorexia troublesome, and patient for some days sustained by nutrient enemata. Since that time up to the present date (July 5th) the patient has improved slightly in general health, the sickness is nearly gone, and she can take milk diet, although with some difficulty. The ankle clonus cannot be made out. The movements of the arms are less pronounced, and those of the jaw muscles and muscles of the eyelids have nearly disappeared. Occasionally, indeed, and especially when the patient is not excited, all the clonic spasms are absent. The turgidity of the face is much less. Temperature and pulse normal, although the latter is somewhat irregular. One symptom which caused her great annoyance in the earlier days of her present attack—viz., insomnia at night—has very much abated, and she now sleeps fairly well.

Digitized by Google

Two days ago, at my request, Dr. Argyll Robertson made an examination of her eyes, and reported as follows:—"Disc hyperæmic; outline dim; retinal veins much congested and slightly tortuous; rest of fundus normal. This condition existed in both eyes, but was specially marked in the left."

Such, gentlemen, is a brief clinical summary of the case at present under our observation. Let us endeavour now to classify the various symptoms, to localise the lesion, and indicate its probable nature. The whole train of symptoms point in one direction, and that is the direction of cerebral hyperæmia. It must be remembered that the prodromata were masked in those of alcoholism, otherwise the intense headache, the vomiting, frequent and not associated with the ingestion of food, the intolerance of light, the mental disturbance, as evinced by confused ideation and illusions, the marked somnolism, approaching stupor, the condition of the pupils, the weak and incoördinate motor power, the jactitations of the arms, and trembling of eyelids—these features, taken collectively, furnish us with an almost perfect clinical picture. The sudden and marked oscillations of temperature, the varying intensity of the clonic spasms of the arms, the occasional and slight ankle clonus, and exaggeration of patellar reflex point in the direction of hyperæmia rather than that of actual infiltration. The intense ophthalmic congestion also favours this view.

The next point which must occupy our attention in the consideration of this case is the extent and locality of this congestion. Is this turgidity general, or is it more marked in certain areas? After a careful investigation of the various symptoms it must be admitted that both sides of the brain are congested, but that undoubtedly the left brain is that most affected. It is upon this side that the headache is most marked and the ophthalmic congestion greater. The fact that the clonic spasms of the right arm were more pronounced than those of the left is an additional evidence in support of this diagnosis. It should be particularly noted that the headache is not increased by tapping over the focus of intensity; a conclusive sign that the dura mater is only slightly involved, if at all. The pain is chiefly limited to the postero-frontal and the antero-parietal regions. We have, therefore, evidently a commencing meningitis, or at least congestion specially marked in the pia mater and superficial layers of the cortex cerebri. This as shown above is most pronounced in a limited area upon the left side of the brain. Before indicating the lines on which the treatment of this interesting case is based, let me for a little direct your attention to the condition of the patient's speech. She is suffering from ataxic aphasia—i.e., an aphasia not characterised by amnesia or loss of memory, but by the loss or impairment of coördinating power over the muscles necessary for the production of speech. When she is asked a question you observe that she answers it, but her articulation is confused and indistinct—in fact, incoördinate. The capability of appreciating with gradually increasing accuracy the site of cerebral lesions has been much enhanced of late years by the work of physiologists and pathologists.

With the aid already afforded them, it is now the duty of clinicians to endeavour to increase this knowledge. The almost speculative presumption of Gall, that the nervous centre for speech is situated in that part of the brain resting on the posterior half of the roof of the orbit, was greatly strengthened by the pathological researches of Broca, who in 1861 affirmed that the second and third convolutions of the left frontal lobe of the brain must be perfect for the production of articulate speech. Since then Ferrier and others have shown by experimental evidence that this nervous centre, as well as that for governing the movements of the upper extremity, are to be found in the area supplied by the middle meningeal artery. This condition of ataxic aphasia therefore only tends to confirm our former opinion that the congestion and irritation were most marked in a limited area of the left cortex.

The prognosis of such a pathological condition of the brain must necessarily be at best a guarded one. The gravity of the lesion, however, is much lessened by the nature of its cause. The fact that it is of syphilitic origin allows us to be much more hopeful than we otherwise could be. In any case the general health of the patient will speedily be affected unless efficient treatment be at once resorted to. If delayed, structural changes soon follow, and insanity, paralysis (from cerebral hæmorrhage), and death may quickly result.

With regard to treatment, the first indication is obviously to remove the cause, if that be possible. In the present case the remoter cause is a diathetic one—viz, syphilis,—and the immediate one, excess of alcohol. The latter has been entirely proscribed, and for the constitutional dyscrasia I have ordered ten grains of iodide of potash to be taken thrice daily. The local measures adopted for diminishing the cerebral or meningeal congestion have been limited to causing the hair to be removed from the head, and the application of the icebag for a very brief period at the beginning of the attack; but, as it caused in a few hours a most depressing action on the heart and temperature, it was soon discarded. Bloodletting by cupping or by arteriotomy of the temporal, or leeching behind the ears, and also all purgatives, have been withheld, because of the patient's very prostrate condition.

The barbarous custom of blistering the scalp is now nearly universally condemned as inefficacious in every form of cerebral irritation, and I have not thought it applicable in the present example. For a successful termination I rely upon rest, careful nursing, simple nourishing food, and the largest doses of iodide of potash the patient can bear. Should amendment fail to follow this treatment, and especially if cerebral pain become localised and more severe, and if, moreover, this pain be increased by tapping, I would assume that the congestion had spread to the dura mater, and would consider it expedient to trephine at an early stage before diffuse suppuration or structural changes had imprinted a fatal aspect on the case.

A few days after the above digest of the case was given severe increasing pain was experienced in the left antero-parietal region, accompanied by a puffy swelling of the scalp at the same part. The pain was intensified by pressure, and the aphasia, sleeplessness, nausea, and sickness were considerably accentuated. The pulse was weak and rapid (120); the temperature only reached 99·4°. The localisation of the pain, the remarkable sensitiveness on pressure, and the œdema of the scalp signalised the extension of the vascular disturbance to the dura mater, and at the same time necessitated consideration of the propriety of direct surgical treatment. The dangers ahead were suppuration, compression, and destruction of a vital organ, and the only efficient alternative seemed to be the chances of relief which trephining might afford. Accordingly, on consultation with my colleague, Dr. John Duncan, I determined to trephine at a point two inches and a half above the anterior margin of the ear in the area of the two anterior convolutions of the brain. The patient was accordingly chloroformed, and a circle of dense sclerosed bone removed, disclosing a dark venous congestion of the dura mater, which was firmly adherent to the surrounding bone, and seemed to be separated from the brain by fluid to the extent of one-sixth of an inch. A puncture was accordingly made, but only serous discharge escaped. The wound was dressed with protective and carbolate of glycerine, covered by a flat piece of sponge and absorbent wadding. The immediate results of the operation were pronounced improvement in the power of articulation and, coincidently, complete and permanent relief from pain. Quiet, refreshing sleep was soon obtained; and when the nausea ceased, the patient was able to eat a more mixed dietary than she had been capable of doing throughout the whole previous course of her illness. The clonic spasms were the last symptoms to amend, and did not entirely disappear until Sept. 16th. The wound healed promptly and the bony circle removed was almost entirely regenerated. The patient is now regaining flesh and strength, is out of bed for part of the day, reads almost continuously, and speaks sentences intelligently with a *staccato* pronunciation. With this exception the nervous system is absolutely normal.

YORKSHIRE ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—A meeting of this Association was held at Hull on the 24th ult. After visiting several places of interest in the town, and being entertained at luncheon by the Mayor, an address was delivered by Mr. S. W. North, the president of the Association, and a paper read by Dr. Mason on "The Sanitary Condition of Hull," in which the author gave it as his opinion that Hull was never in such a good sanitary condition as at the present time. A discussion followed, in which Dr. Hime (Bradford), Dr. Hardwick (Rotherham), Dr. Wilson (Doncaster), and other gentlemen took part. Subsequently a paper was read by Dr. R. Bruce Low, of Helmsley, on "Rural Sanitation."

SYPHILITIC AFFECTION OF CEREBRAL NERVES;

WITH OBSERVATIONS.

BY HENRY LEE, F.R.C.S.,
CONSULTING SURGEON TO ST. GEORGE'S HOSPITAL.

CASE 1.—A gentleman came under my observation on July 17th last, who had had fever in India, followed by loss of power in the right leg, in 1881. From this he completely recovered. In October, 1883, he contracted syphilis, and secondary symptoms appeared in November following. When I first saw him his hearing was impaired, and he had constant singing in the head. The whole of the muscles supplied by the portio dura of the seventh nerve were paralysed on both sides. This had produced a very peculiar expression of countenance: the lower lip had fallen; the food lodged between the cheek and the teeth; he was unable to close his eyes; he never smiled; and when talking he artificially supported his lower lip with his finger, but even then his articulation was very peculiar; sensation of the skin of the face was perfect. He commenced a course of calomel baths on July 17th, and was directed to take a pint of the simple decoction of sarsaparilla (L.P.) daily. On Aug. 12th his hearing had improved, and he could bring his lips together and nearly close his eyes. On the 25th he had regained the motion on the left side of his face, some singing in the ears still remained, and, as he said, "the food still sticks a little in the jaw." During my absence from town this gentleman wrote to me, saying that, at the urgent solicitations of friends, he had been induced to place himself under the care of a "specialist for the nerves," so that he might be treated in the country.

The simultaneous affection of the auditory nerves and nerves of motion clearly point to the origin of the seventh pair as the seat of the diseased action in this case. The pathological condition is as clearly demonstrated as in Sir Charles Bell's experiments. In fact, the conclusions are, if anything, more satisfactory, as the patient could describe his symptoms. In Sir Charles Bell's first experiments he was, no doubt, led to a wrong conclusion. On dividing the branches of the fifth nerve in a donkey he observed that the lower lip dropped, and he then concluded that the fifth nerve was a nerve of motion. This error was subsequently corrected, and it was satisfactorily shown that upon the division of the branches of the fifth nerve in an animal the lower lip fell and the food escaped out of its mouth, because the regulating power, the power of feeling, was gone. In Sir Charles Bell's first essay, published in the Philosophical Transactions for 1821, he represents the seventh nerve as controlling the instinctive actions, but not the voluntary actions, of the face. In support of this theory Sir Charles Bell observed that after dividing the seventh nerve on one side the animal still continued using its lips in taking food. The motor nervous influence was withdrawn from one side only of the orbicularis oris, but not from the other. When the seventh nerve was divided on both sides the muscles of the cheeks, the muscles of the lips, as well as of the nostrils, were completely paralysed.[1]

CASE 2.—A married gentleman had syphilis some years ago, for which he appears to have been imperfectly treated. After the secondary symptoms had subsided, the parietal bone on the left side became enlarged to a considerable extent. There was some loss of power in the right leg; this was occasionally better and occasionally worse. After the lapse of many months he had a fit and became unconscious, and there was some loss of power in the right arm. His memory at the same time suffered. The point of interest in this case was that for many months the power of adjusting the focus of the *left* eye was impaired. This was tested on several occasions and at long intervals, always with the same result. He saw well at a distance with the right eye, but was ordinarily short-sighted with the left. By an effort of the will and after a few seconds he could focus the left eye to the same distance as the right, and see as well with one as with the other. On looking along a narrow ruler with both eyes the extremities of the ruler appeared to diverge, "so as to make a very closely formed X." There was nothing the matter with the eye itself, nor was there the least indication of any branches of the sympathetic being affected. The change of focus was produced entirely by a voluntary effort. The ordinary motions of the eye were perfect.

The very interesting question then arises, Upon what condition did the imperfect adaptation of the eye to vision at different distances in this case depend? Since Sir Wm. Bowman made the discovery of the mode in which the eyes are adapted to vision at different distances by a mechanism within the eye itself, little attention appears to have been given to the influence of the external muscles of the eye in producing the same effect. This subject, however, occupied the attention of former physiologists. The fact that the eye is naturally flaccid, and liable to different degrees of tension, indicates that by slight pressure its diameter may be altered. Extreme tension, which prevents any sense of fluctuation, indicates very serious disease. Short-sighted persons are constantly in the habit of half-closing the eyelids so as to make slight pressure on the anterior surface of the eye in looking at distant objects. The antero-posterior diameter of the eye is thus slightly shortened. The action of the external muscles on the eyeball might be called the coarse adjustment of the eye in contradistinction to the fine adjustment by the mechanism within the eye itself. The antero-posterior diameter of the eye may be lengthened as well as shortened. Dr. Hosack[2] says that external pressure is capable of altering the focal length of the eye. With a speculum he made pressure upon his eye while directing attention to an object twenty yards distant, and saw it distinctly. Endeavouring to look beyond, everything appeared confused. Upon increasing the pressure considerably he was enabled to read a book distinctly held at a distance of two inches from the eye, although in the natural state of the eye he could distinguish neither lines nor letters. This experiment may easily be repeated in a very rough way. If a book be placed before the eyes so close that the type can no longer be distinguished, and pressure be made through the upper eyelid deep into the orbit, the type will become more distinct. In all animals, birds, and fish the muscles which in man are called oblique are really transverse. The superior in all has its special nerve, the fourth; while the external rectus in like manner is supplied almost exclusively by the sixth. Sir Charles Bell has shown that with regard to opposing muscles when one acts the other relaxes, or loses its tone, so that they act in concert although not supplied by the same nerve.

Now, we have in the eye the external and internal rectus, which taken together have a double supply of motive nervous power, the one for the ordinary motions of the eye; the other to regulate the degree of divergence from the usual axis of vision.[3] In like manner the two oblique or transverse muscles taken together having a double nervous motor supply must have a double function. The first, that of rolling the eye so as to enable it to follow a revolving object sufficiently long to produce distinct vision; the other has not been generally acknowledged. Considering the disposition of the oblique or transverse muscles in all classes of animals, the action must be (when they act together) to compress the eye laterally and then slightly to alter its antero-posterior diameter. In dissecting the eyes of animals I have found a thick cushion of fat on the inner side of the eye. This, during the action of the oblique or transverse muscles, would afford a slight resistance and compress the inner surface of the eye.

Irritation of a nerve has a natural tendency to increase the susceptibility, and, if long continued, the development of the muscle which it supplies. A familiar instance of this is shown in the case of children who, from some reflex irritation, begin to squint. If the irritation be long continued, the strabismus becomes permanent. A very remarkable case occurred under my observation some years ago, which illustrates the same point. A young girl had her little finger drawn across the palm of her hand, so as to prevent her closing the other fingers. After a variety of ineffectual treatment, Sir William Fergusson removed the finger,

[1] Vide May's Physiology, p. 174, and Cæsar Hawkins, THE LANCET, March 15th, 1856. A well-marked pathological case such as that above described might have given the same conclusions with regard to the functions of the seventh nerve as those arrived at by so much toil and so many experiments. It is curious that Sir Charles Bell's first experiments illustrate his own words—that we can seldom rely upon the answers that are extorted from living animals by experiments which go counter to the natural feeling of mankind.

[2] Philosophical Transactions, 1794, Part ii., p. 222.

[3] The influence of the sixth pair of nerves must be of very especial service to animals, such as the hare, that look behind them in running.

Digitized by Google

Upon dissecting the parts, I found that the adductor minimi digiti was enormously developed. After a time the ring finger was drawn across the hand in the same way.

The conclusions to be drawn from the foregoing observations are—first, that the focal length of the eye may be altered by external pressure; secondly, that the mechanism by which this is usually effected is under the control of the fourth nerve; and, thirdly, that prolonged irritation of that nerve, direct or reflex, and of its corresponding muscle produced the comparatively and permanent short-sighted condition of the left eye in the last recorded case.

Savile-row, W.

ON THE

NERVOUS OR MUSCULAR ORIGIN OF CERTAIN SPASTIC CONDITIONS OF THE VOLUNTARY MUSCLES.

BY SYDNEY RINGER, M.D.,
PROFESSOR OF MEDICINE AT UNIVERSITY COLLEGE, LONDON,
AND
HARRINGTON SAINSBURY, M.D., M.R.C.P.,
ASSISTANT PHYSICIAN TO THE ROYAL FREE HOSPITAL.

OF late years the method of pathology has been, and is still, becoming more and more experimental. The like is true of therapeutics, experimental pharmacology becoming daily more recognised as an important means of study. Experimental pharmacology is, however, able to do more than teach us in therapeutics, it is able also to render important services to pathology itself. The following paper is offered as a pharmacological contribution towards experimental pathology.

In experimenting with drugs a striking fact is everywhere apparent—viz., that we may reproduce the facsimiles of disease in the laboratory. We may illustrate this statement sufficiently by examples taken from two important genera of disease—e.g., if from that kind of morbid action which manifests itself in the shape of over-action of the muscular apparatus—i.e., spasm,—if from this we select tetanus as an example, we can at once put against it as pharmacological counterpart the effect on the organism of strychnine in toxic dose. Still better examples do we get from that kind of morbid action which manifests itself in the shape of under-action of the muscular apparatus, to which we apply the name paralysis. Pathology has taught us concerning this form of disease that it may be of cerebral, of spinal, of peripheral origin; and pharmacology enforces this teaching by presenting us, as the result of drug action, with each of the above varieties of palsy. Thus the group of the anæsthetics, including chloroform, ether, nitrous oxide, may probably be considered as of value chiefly in that its members abolish the functions of the cerebral cortex, motor and sensory (the sensory effect is in excess of the needful here). Then to illustrate by drug action the second group, that of the palsies of spinal origin, we may take physostigma, the action of which is paralysant by depressing the functions of the cord; lastly, to illustrate the third group we may take curare, this drug, as is well known, effecting paralysis by abolishing the functions of the motor nerve endings. It may be said that we have not pushed our examination very deeply and have not attempted to decide, in the case of physostigmine action, whether the paralysis is the result of action on the moter or on the sensory areas of the cord; but this was not the problem before us. We had simply to present, as the result of drug action, a paralysis of spinal origin; the further analysis is not called for.

These few examples will suffice to show how much pharmacology may aid us in the study of disease, since, enabling us as it does to actually produce disease, to multiply its causes, it thereby enables us, by a careful comparison of these causes, to separate the essential from the non-essential, and so to arrive more nearly at a just appreciation. This is the object we have in view in the present paper—viz., to compare certain effects, the result of drug action, with certain other effects (symptoms) the result of disease. We shall begin by first describing the real thing and then proceed to its simulacrum.

There has long been known as an occasional symptom in certain nervous disorders a condition of the muscles, marked by rigidity. Thus in cases of cerebral lesion—e.g., apoplexy,—we are familiar with the so-called early rigidity of the paralysed parts, probably an irritative effect, and also with the rigidity which supervenes more remotely, and is hence known as late rigidity; this latter is probably significant of cord implication, the result of a descending degeneration. Then in various primary diseased conditions of the spinal cord we may meet with this rigidity of the muscles; thus in lateral sclerosis of the cord, likewise, and probably in virtue of the same, in disseminated sclerosis. In the so-called spastic paraplegia of infants we again meet with the same symptom; in this case it may be observed that the pathology is still obscure, and that it is uncertain whether a cerebral or a spinal morbid state underlies the symptom.[1] Lastly, we have in what we term cramp, or cramps, tonic spasm of certain portions of the muscular system, the simple forms of which we are in the habit of regarding as local affections.

In all and each of these cases the question arises, What share are we to attribute to the muscles themselves—what to the nervous system? In how far is the pathology myopathic or neuropathic? This question is none the less pertinent that we have just seen the symptom we are considering in association with disease of the cerebrum and of the spinal cord, for there still remains to determine in how far cause, in how far coincidence is before us.[2]

A very valuable aid towards answering the above question on clinical grounds has been gained of late years in the appearance of a disease which has been named Thomsen's disease, though most accurately described before Thomsen by Leyden. The literature on the subject of this disease is chiefly German, though more recently a very valuable article on the same has been contributed by Messrs. Ballet and Marie.[3] Amongst German literature the article by Bernhardt[4] is very complete, and we shall follow chiefly in his lines in our description. To bring out the characteristic features of the affection it will be perhaps best to take an imaginary case and endow it with the several symptoms which have been observed in the cases hitherto recorded.

The patient we will suppose to be a man[5] in early adult years. His complaint is simply and solely of muscular stiffness—nothing else. His appearance is that of health, and it will be found on questioning him on this point that there is nothing manifestly wrong. His past will likewise very possibly show a clean bill of health, with the exception of the affection of which he now complains. As to this his memory will probably carry him back to early childhood. This dating back of the disease to early childhood comes out very abundantly, and is an important feature in the complaint. In one of the three cases published by Seeligmüller this history did not obtain, the patient stating that the affection had appeared suddenly, some four or five years previously, as a stiffness affecting one leg, the left; and that subsequently the other limbs had become implicated. Seeligmüller[6] rises to the occasion, and thinks that the patient had previously suffered from the complaint, but had not noticed it! Be this as it may, the recognition of the disease at a very early date remains a generally observed fact. Hence for most authors the affection is congenital.[7] Passing to the patient's family history, we may very possibly find that the mother or the father has suffered in the same direction, or, in the absence of such, that a brother or sister is similarly troubled. So marked a family history as in the case of Dr. Thomsen, in which in three generations at least we trace the complaint, we shall scarcely look for. The evidence then obtainable from the family history will give prominence to heredity. We have thus traced back the complaint into the life of the patient himself and into that of his family. What, now, is this complaint more definitely? It is that in the performance of certain voluntary movements the patient finds himself hampered. Thus, should the patient flex vigorously his

[1] Leyden, discussing this question of muscular rigidity, states that it occurs not infrequently in cases of spinal cord disease, and, as he believes, "in association with various diffuse processes of the motor areas."—Klinik der Rückenmarkskrankheiten, 1874, Bd. I., pp. 123, 129, *et seq.*

[2] Under the heading "muscular rigidity" we have not mentioned the rigidity met with in the cataleptic state; yet this also must be included in a sufficient pathology.—Op. cit., p. 128.

[7] Thomsen has observed the affection in his own family, even in the cradle, Archiv. f. Psychiatrie u. Nervenkrankheiten, Bd. vi. (1876), p. 709.

Digitized by Google

arm at the elbow he may find for a few seconds that he is unable to extend it again. Should he perform full vigorous flexion of the fingers on the palm, as in grasping the hand, he may find the same difficulty, which trouble is also shared by his friend, who may, as one of the authors tells us, have literally to free his hand as from a vice. Clearly the affection is likely to lead to embarrassing situations, and some of the recorded facts are decidedly comic. We have described the arms as affected. We shall almost certainly learn from the patient that the lower limbs suffer similarly, and, indeed, in a higher degree than the arms, the patient being seized with the stiffness in the act of rising from a sitting posture, in the act of mounting his horse,[8] in the first movements of walking. This leads up to the very important fact we must record—viz., that this peculiar stiffness is especially observed *at the commencement of volitional movements;* indeed, as the movement is repeated the stiffness wears off, and may completely disappear, the patient then being as nimble in his movements as the rest of the world.[9] Along with this stiffness we shall learn from the patient that there is associated a peculiar sensation, very apparent to him, but rarely amounting to pain, and therefore very different from the sensation accompanying cramp proper. This is appreciated best by observing that the patient does not come to you for the pain, but almost solely on account of his unmanageable muscles.

We have mentioned the muscles of the lower and of the upper limbs; may others suffer in this affection? Yes. In our conversation with the patient we may possibly have noticed that an unusual movement of the muscles of expression has been slow to resolve itself; this has become yet more evident on asking the patient to voluntarily contort his face. Of the transitory Medusa effect following such contortion the patient is himself conscious as a stiffness of the face muscles. Another thing may have struck us—viz., a slowness, an awkwardness in the patient's speech which, on the theory of a participation of the tongue muscles in the general muscular affection, is readily accounted for. Finally, we may have observed that the movements of the eyeballs are not quite free, and the patient will tell you as much. Thus he finds himself unable at times to turn his eyes suddenly in a given direction, or if the movement obtains it does so haltingly. Each one of the points just enumerated finds exemplification in Leyden's case;[10] in this, moreover, the affection of the tongue muscles was tested by making the patient protrude his tongue and then telling him to rapidly carry it from one side of the mouth to the other; the result in many cases was temporary fixation in a midway position.

Proceeding in our examination, we shall, on making the patient strip, note unusual muscular development, to the extent even of warranting the term athletic. This muscular development may, as in the case of one of Thomsen's children, be quite out of proportion to the bony framework; yet Thomsen refuses to call the muscles hypertrophic. As Seeligmüller and Bernhardt point out, the question is one of a definition of terms. Of the parts of the body affected, we shall note that the muscular hypertrophy finds accentuation in the lower limbs, and in particular affects the muscles of the thigh and calf—i.e., the hypertrophy is most marked in those muscles which are most liable to the spastic seizures; next, passing to the trunk, we may very likely find the sacro-lumbar muscles on either side of the spine decidedly more massive than is natural; and, associated with this, we may also find present a well-marked lordosis. This was so in Bernhardt's case. Thus far, from inspection, we cannot fail to have been struck by the likeness to pseudo-hypertrophic paralysis; and in Bernhardt's own case this was the *primâ facie* diagnosis. Proceeding upwards, the muscles of the upper extremities will probably be noted to be well-developed, but the term hypertrophy will be less fitting. Visible hypertrophy of the face muscles we shall not observe.

If we now test the muscles we may in the first place discover that even whilst at rest they are of firmer consistence than normal. Thus Seeligmüller describes the muscles in one case as of board-like hardness, in another as stony, in the third as being simply firm. In Bernhardt's own case they are simply described as being firm, and in Ballet and Marie's case the consistence is only doubtfully increased. Increased consistence then will be an occasional but not very characteristic feature of the muscles at rest. When thrown into action, however, the muscles will be observed to harden and to stand out in relief, and to persist in this state during the whole time of the impeded movement.

With this we about conclude the list of positive symptoms, and they may be very quickly summed up as follows. We have an affection of the voluntary muscles marked by the supervention of a spastic state on the act of contraction. This is marked for first volitional acts, but soon wears off with repetition of the act. The muscles generally are affected with this stiffness, though certain ones suffer more than others. The affected muscles are increased in bulk, but doubtfully in consistence.

Further examination reveals a long list of negatives. Thus the muscles tested by the dynamometer reveal nothing in the shape of lack of power, the athletic appearance is not contradicted. The condition of the parts around reveals nothing abnormal, no excess of the panniculus adiposus; the surface of the skin healthy-looking, no marbling; sensation, with one exception (Seeligmüller's), intact; of touch, temperature, pressure, pain, in each case the sense is recorded as normal; in addition the muscular sense is preserved. Electric examination in like manner yields almost negative evidence, for though peculiarities in the mode of reaction are recorded, nothing of the nature of the reaction of degeneration is discoverable. Ballet and Marie's paper is the most detailed on this point. They submitted their patient to a very careful electric examination, the results they summarise thus. *The muscles and nerves are less excitable than normal, but there is no marked deviation from the normal formula.* The slight deviation was that for certain of the muscles the anodic closure contraction was "precocious" as compared with the cathodic; also, another point, that the anodic opening contraction was completely absent. The characteristic effect which, however, comes under the heading of *peculiarities* was the readiness with which the contractions electrically excited became spastic. This of course is simply what we should be prepared for having seen that the same peculiarity marks the effect of stimulation of the muscles through their motor fibres by the will. In the absence of the spastic state Ballet and Marie did not observe anything abnormal in the muscle curve obtained with a Marey's drum. In Leyden's case the electrical reactions are recorded as normal. In Bernhardt's the reaction formula is said to be normal, but we find noted as a peculiarity that short excitation, electric or mechanical, yields a local contraction outlasting considerably the stimulation—i.e., the contraction tends to become tonic. Seeligmüller's experience is of a precisely similar kind. We may take it then that beyond the peculiarity of the persistent contraction nothing noteworthy has been observed electrically.[11] Examination has been pushed yet further. Thus we have two records of microscopical examination of the muscular fibres, one by Ponfick, the patient being one of Thomsen's sons, and the fibres extracted from the biceps muscle. To Ponfick's astonishment nothing faulty was found. The like negative results were obtained by Petrone, an Italian observer.[12]

[8] Ballet and Marie, op. cit.

[9] We shall probably learn from the patient that certain conditions predispose to the development of the spastic state—thus fatigue, prolonged exercise, cold, conditions obviously depressant to the organism.

[10] Op. cit. In Ballet and Marie's case the same trouble wich the movements of the eyeballs was observed, as also with the tongue movements. Likewise in a case recorded by Schönfeld.—Virchow u. Hirsch: Jahresbericht, 1884 (Jahrgang, 1883), p. 77.

[11] Mobius, Virchow u. Hirsch (Jahresbericht, 1884, p. 76), records similar results from electrical examination in a case of Thomsen's disease. Schönfeld (op. cit., p. 77) records "no electrical abnormality."

[12] See Ballet and Marie's paper, loc. cit.

(To be concluded.)

FIRE AT SALFORD UNION HOSPITAL.—On the 24th ult. a fire occurred in the padded room of this hospital, in which a lunatic was confined, and which resulted in the death of the unfortunate man. The fire, which was extinguished without difficulty, is supposed to be due to the destructive tendencies of the occupant of the room. It is surmised that he first succeeded in making a hole in the canvas with his finger-nails, and then ripped the material so that he was able to climb up the wall until, reaching the fan-light over the door, he smashed the glass and applied some of the straw padding to the gas jet which was burning outside. The fan-light is fully ten feet from the floor, and it had been thought impossible for anyone to get to it without something to stand upon. At the inquest on the 27th ult. the jury, after some consultation, returned a verdict that death was caused by burns received in the padded room of the hospital, but that there was no evidence to show by what means the fire originated.

CHOLERA.[1]

BY MAX VON PETTENKOFER, M.D.,
OF MUNICH.

CHOLERA is an infectious disease. By infectious diseases are meant those diseases which are caused by the reception from without of specific infective material into healthy bodies, which material acts like a poison. To the list of infectious disorders belong such different maladies as small-pox and intermittent fever. Infective material differs essentially from lifeless chemical poison in being composed of the smallest possible units of living matter which when taken into healthy bodies rapidly increase and multiply under certain conditions and by their life-growth disturb the health of the body. These germs of disease belong to the smallest units of life, to the schizomycetes, which lie on the borderland of the invisible, and which, according to their form, are known as cocci, bacteria, bacilli, vibriones and spirilla, and thirty millions of which, according to Naëgeli, hardly weigh one milligramme. Infective material is derived partly from sick individuals, in which case the disease is termed "contagious" and partly from locality (earth), in which it has developed, in which case the resulting disease is termed "miasmatic." It is obvious that when derived from both sources the resulting affection was, and even now is, designated "contagio-miasmatic." I am of opinion that the terms "contagium" and "miasm," which have given rise to much misunderstanding, would best be dispensed with altogether; and that the designation "infective material" (Infectionstoff), which is common to both contagium and miasm, should be divided into entogen and ectogen, according as the material is obtained from the sick body or the locality (soil). According to many, cholera would belong to the entogenous section, and according to others to the ectogenous division. The supporters of the first view might be termed "contagionists"; the supporters of the second "localists." As is always the case in medicine, the conflict of views is important, inasmuch as the measures to be adopted in the healing and prevention of a disease depend on the theoretical conception of it.

All readers know that cholera originated in the East Indies, and most individuals are also aware that the epidemic spread into Europe in the present century (1830). We shall first speak of its age in India, the home of cholera. There the disease appears to have existed at all times; not only at the time of the discovery of the sea passage to India by the Portuguese, but long before, as the oldest Sanskrit writings show. Many hundreds of years before the birth of Christ the disease was accurately described and its epidemics spoken of as attended with *mahâ mârî* (*magna mors*, great death). In these writings the disease appears under widely different names, which are taken from the chief symptoms:—(1) *Vishâ dschikâ*, vomiting and sweating; (2) *alasikâ*, cramps which bring on exhaustion and stiffness; (3) *rilambikâ*, which is perhaps best translated by the term "collapse." Another word which is often used in India is taken from the Mahratta, *mordeshin* or *mordeshi*, which has been translated into French as *mort de chien*, but which also means "collapse."

In the seventeenth and eighteenth centuries A.D. there are abundant proofs and descriptions of epidemics of this disease. The disease is best known in Europe under the names of cholera, cholera morbus, Asiatic cholera, since the epidemic of 1817 to 1819, in which the English army under the command of the Marquis of Hastings during a war against the natives was rendered unfit for fighting and almost annihilated. But cholera had never visited Europe till the present century, when in 1830 it appeared in Russia and spread to Poland, where war was prevailing. Since that time, sometimes at longer and sometimes at shorter intervals, cholera has appeared in Europe. The question why cholera remained a thousand years in India before it first began to migrate is one of great interest, but one which cannot be satisfactorily answered. The principal consideration appears to me to be that the event happened at the time when intercommunication in all directions, both by water and land, had become more rapid. The first steamship appeared in the Indian waters at the beginning of the second decade of the present century. By land also intercourse was greatly accelerated. The Russians possibly took cholera from India, Arabia, Afghanistan, or Persia, through couriers and stage coaches. It soon became clear that cholera, the specific cholera germ, was in some way or other propagated along the paths of human intercourse, and it also became evident that unless the germs found a suitable soil within a certain time they did not flourish. Observers soon discovered that cholera was more prone to appear in certain regions and to affect certain localities, whilst it shunned other districts; and, again, that other regions were only visited at intervals of many years. It is also a fact that Asiatic cholera never yet appeared at a place which had not previously been in communication with a region where cholera prevailed; and, further, that the disease from an infected locality never yet passed on to another place if the journey lasted a certain time without interruption. The large intercourse between India and Europe, more particularly England, by means of ships which sailed round the Cape of Good Hope, had never succeeded in carrying cholera from India to England; it was only by the overland route that cholera reached England. Neither had the Cape or Australia ever been visited by cholera. It is possible that in the future the communication may be so much accelerated that cholera may get to these countries. In much the same way South America escaped during the epidemic (1830–1840) in Europe and North America. It was supposed that in South America yellow fever was enough to prevent cholera, or that this disease kept out cholera, until suddenly, in 1854, after a service of fast sailing vessels between Philadelphia and Rio de Janeiro had been established, the chief town in the Brazils experienced a terrible epidemic of cholera. When cholera passes overland it dies out unless it find a suitable soil within a certain time. Rainless deserts are unfavourable to cholera. Caravans which pass from infected localities through deserts have never spread the disease, provided the journey in the desert lasted at least twenty days.

Cholera always requires for its propagation favourable stations on land, and as a rule, if the course of epidemics be traced, a gradual extension in successive years is found to take place in fixed directions. In the east and south-east of Russia, for example, cholera prevailed after it had raged in Persia in 1868; in 1869 eleven, and in 1870 thirty-seven, provinces were affected, and amongst them five districts in Poland. In the year 1871 the epidemic spread into the west, east, and north of Russia, and succeeded in reaching East Prussia, when Königsberg was severely visited, so that from July 24th to November 8th 2012 individuals died there of cholera; whilst in Berlin only 52 and in Potsdam only 71 succumbed. In 1872 the epidemic reached Eastern Hungary, and in the following years reaped rich harvests in Germany. It has rightly been said, therefore, that cholera does not travel quicker than man. Nevertheless, the spring-like mode of progression of cholera is noteworthy: for example, it regularly jumps from Marseilles to Paris, or *vice versâ*, passing over Lyons, the second largest town of France. Or, watching the passage over smaller distances, in 1854 it went from Munich to Augsburg by railway, leaving intact the ten intermediate stations, although several patients alighted and some even died, and, notwithstanding that cholera raged at Augsburg and Lech, it never once sprang over the valley of Lech to the town of Friedberg, which is but a league distant. Or to take a still narrower circle, cholera thrice (1836, 1854, and 1873) invaded Munich, and every time halted in those houses situated on the clay soil in the suburbs.

The capriciousness of cholera may be observed in its relations not only to space but also to time; at one time it infected Prussia and shunned Saxony, while at another it did exactly the reverse. In the year 1849 Berlin experienced its worst epidemic, an epidemic in which Saxony was but slightly affected (488 cases), and Bavaria not more so. In the year 1850, when the cholera in Berlin and its environs had almost subsided, the epidemic raged in Saxony until 1551 deaths occurred, though Bavaria was not involved. In 1854 the matter was altogether different; then Munich and Bavaria had its worst epidemic, at which time the Industrial Exhibition was held at Munich, and the intercourse between Munich and Saxony and the whole of Germany was very active. The cholera did not, however, spread to Saxony. All the fatal cases of cholera in Saxony had taken the disease from Munich. The epidemic did not spread further north; yet the inhabitants

[1] Specially translated for THE LANCET from early proof-sheets furnished by the author.—ED. L.

Digitized by Google

of Saxony and Prussia had sufficient susceptibility for the disease, as was proved when they went to Munich. It was in the year 1855 that a change occurred; then Bavaria was exempt, and the epidemic devastated Saxony and North Germany. What relation the extension from India by the agency of man may have to conditions of time and space, to local and periodical disposition, has yet to be worked out; but the fact of the existence of relations in time and space is as undeniable as that of cholera itself. The cholera germ alone will not explain everything. We must now inquire into the differences between places which are and those which are not susceptible, and endeavour also to trace out the relations in time which obtain in susceptible places.

No doubt can be entertained that the configuration of the earth has a certain influence. Relatively low-lying sites are very favourable to cholera. Where the surface of the earth has an undulating outline it will be found that districts and individual houses which are situate on the summit of the undulation very frequently have no, or only a very small, disposition to the development of an epidemic of cholera, whilst in the hollow of the undulation under like conditions the opposite holds good. The truth of this statement is seen in single districts where parts or single houses exist on the summit and others lie low.

Another feature which is found in every epidemic is the falling off of the disease in the neighbourhood of and on mountain ranges. The Himalayan mountains, those of Lebanon and the Alps, have always formed the places of refuge for fugitives from cholera. Now and then an epidemic occurs in the mountains; these exceptions will be dealt with later. The immunity, or the slight susceptibility, of mountain ranges for cholera is witnessed in India as plainly as it is in Europe. A familiar example is the complete freedom from cholera of the hill stations along the Himalayas, in which, through frequent changes of troops, the cholera has every chance of being taken up from the plains. In the severe epidemic of 1869 there were only two cases of cholera in nineteen hill stations. A similar experience is met with in narrower areas. For instance, in Munich, 1873-74, the frequency of cholera was widely different in the seven barracks of the garrison. In the low-lying Isar Kaserne (occupied by cuirassiers, heavy cavalry regiment), out of 1000 men there were 40 cases of cholera; in the high-lying Max II. Kaserne (with two field artillery regiments) only 3 cases, and this without there being any difference in the construction of the caserns, the occupation or the diet of the men or the drinking water. Another local factor, which is also very evident, is the nature of the soil. Where the soil is compact, and not, or very slightly, permeable for water and air, the development of cholera is much hindered. Some time ago Jameson, in his description of the epidemics of 1817 and 1819 in India, said, "Cholera does not appear to like a rocky soil." French epidemiologists (Boudée and others) have said the same thing. I studied this point in Bavaria in 1854, and then collected so many facts that I came to the conclusion that cholera requires for its epidemic development a porous soil through which air and water easily percolate, and that a compact soil was decidedly inimical. It will be sufficient to give a couple of illustrations. When the cholera broke out in Munich the inhabitants scattered themselves on the mountains. Many settled in the valleys, where several fell ill and died. The greater part of the town in which the better hotels were situate lies upon compact chalky soil, and the smaller part was built upon alluvial soil. In this part the cholera assumed an epidemic character. In the higher lying districts (Schrödelgasse) the epidemic began in the beginning of August, and in the lower lying areas towards the end of September, whilst the greater part situate on chalk was not affected. Amongst the Jura mountains to the left of the Donau lies a village called Kienberg, which is built on rock. In this village the cholera broke out so fiercely that within a month 30 per cent. of the inhabitants died. When I went there I found many houses emptied, whilst other houses had not had a single case of illness. I then thought that the drinking water was at fault. But the whole village drew water from a single spring at the foot of the slope on which the village was situate. From a study of the soil I found that all the houses built upon porous and rather loamy sand had been attacked, whilst those which lay upon the compact soil of the Jura rocks had escaped. The greater part of Kienberg stands upon a cleft of the mountain which had been filled up by fine soil which had resulted from the wasting down of the higher parts of the mountain (alluvial soil). That some doubt should be thrown on the decision of the commission which had adopted my views on the influence of the natural state of the soil on cholera was not to be wondered at. I spared no pains, however, in going to the Krain and Karst mountains, where cholera apparently was raging on a bare rocky soil, and instead of contradiction I found a further corroboration of my views. The towns lying amongst these mountains were found to suffer from an affection which unquestionably proceeds from the soil—namely, ague. The mountains are freely cleft, and the clefts are filled with porous soil, allowing of the free percolation of water and air, so as to be nothing more than an alluvial soil. Here streams rush down the mountain side, turn off at its base, and run on richer still in water. You may often find there a cleft having the shape of a funnel, filled with porous earth; the nature of the cleft and its contained earth may be determined by sinking a so-called Dolione, when the bottom will be found to be solid stone. Through the Adelsberger growth the rapid Poik flows; and on the other side of the mountain in which the grotto is situate the waters of the Poik roll off under the name of the Unze; the Unze again flows off at the base of a mountain, as a navigable river, on the other side of Laibach. As I proceeded from Laibach to Novomsto (Neustadtl), I saw shining in the distance before me and far below the mountain a village which turned out to be Rasderto, where, as I learned from my companion, a schoolmaster, that ague prevailed, and, indeed, I found many sufferers confined to bed from this complaint. Rasderto lies below the sites which the cholera infested. At the base of the rocky hills on which Rasderto is situate there flows a stream which is so powerful that it turns a mill.

In order to study the cholera at Malta I proceeded thither in 1868 at my own expense. Mr. John Simon procured me the necessary introductions. On arriving in the harbour of Valetta I was forcibly struck with the rocky nature of the soil. The rocky hills rose high above the water, and on alighting on shore my feet encountered the resistance of bare rock. I ascended the steps hewn out of the solid rock, by which means I reached the plateau, on which the greater part of the town is built. A promenade, which was also shaped out of the natural rock, led me to my hotel. I now became very desirous for a further study of the place. Mr. Inglott, at that time the chief medical officer of the hospitals in Malta, and Dr. Pisani, a distinguished Maltese physician, rendered me very efficient aid in my researches. They often wondered why I had determined to visit Malta. How often did they say to me when I questioned them on the nature of the soil of this rocky island, "Our rock is not rock in your sense of the term, but it is a sponge which sucks up everything which falls upon it"? Investigation proved that the Maltese rock was as porous as Berlin gravel, and that more than a third of its volume consisted of air-containing pores. It is so soft that it can be cut and sawn like wood. As visitors may purchase wood carvings from Oberammergau and Berchtesgaden, so one can obtain carved work of Maltese stone. Tiles cut from Maltese stone find a ready sale in Italy, where they serve to decorate the floors of rooms, where, owing to their porous nature, they are not so cold to the feet as stone tiles. Maltese tiles are as good as wood without being so inflammable. Moreover, of the same stone vessels are made which English sailors use to filter their drinking water. Turbid water when poured into such vessels filters off as a transparent fluid. It will be readily understood that I now no longer concerned myself as to an explanation when I heard that an epidemic of cholera had broken out at a place which apparently had a compact soil.

Not only does the physical nature, but also the chemical constitution, of the soil have an influence on the occurrence of cholera—to wit, the presence of organic matter and water. The influence of the soil on the development of infectious diseases can only be understood by a study of the organic processes which take place in it. The processes are eventually dependent on the action of the lowest organisms, which require for their growth a certain temperature, so much water, air, and food stuffs. In order to explain the occurrence of cholera on such varied soils as those composed of granite, sand chalk, and shell chalk, we must suppose that the soil contains in its interstices much organic matter and water. Farmers know how useless pure soil is, whereas the luxuriant growth of plants when the ground is manured is well known to all. These observations are applicable to the lowest plants, the bacteria, no less than to grain and vegetables.

Digitized by Google

The germs of putrefaction and fermentation abound in the free atmosphere, but they only grow and multiply where they find suitable food. The hygienic uses of cleanliness here find their explanation and scientific foundation. The refuse from houses, dissolved or suspended in water, forms an excellent nutritive material for the lowest organisms which are so harmful to us. Emmerich has shown that the purest water after being used to clean the floor of a room contains in a very short space of time abundant germs of disease, so much so that a drop of it injected under the skin of a rabbit or guinea-pig is followed by a fatal result. With this dangerous slop-water it is the custom to charge the earth in and about our dwellings. Since man began to live in towns where drainage was in vogue, diseases dependent on conditions of soil (cholera and typhoid fever) have undergone a striking decrease. Just as a field, when excessively manured, does not always remain good for vegetation unless remanured, so is it also with the uncleanliness of the soil in the neighbourhood of our houses. As soon as we cease to make unclean—to manure—so soon do our towns begin to purify themselves, just as a churchyard after a time becomes purified. In a similar fashion does good drainage act in cleansing our towns, and the necessity of a pure water-supply is thus vindicated. It is in this way that, according to my views, cleanliness acts as a deterrent to cholera. Cholera germs may come, but they cannot fructify under such circumstances. That sites naturally exist which, without human interference, are unfavourable to cholera has already been shown.

Where water entirely fails the organic processes soon come to an end; this is true of the soil of the earth. In rainless deserts the soil is dry except the most superficial layer during the night. In such desert places no organic processes can go on; this is shown not only in the absence of vegetation, but may be proved by an investigation of the nature of the air of the soil ("Grundlutt"); this air under ordinary circumstances contains much carbonic acid, which proceeds from the processes of organic life; but where the soil is free from water the air of the soil much more closely resembles that of the atmosphere above it. This fact has been experimentally proved by Prof. von Zittel by a comparison of the free atmosphere with the air of the soil of the Libyan desert. These observations are believed to explain how it is that cholera does not appear on a very dry soil. Just as too much water is bad for certain plants, so is it also for some members of the lowest class of the vegetable kingdom. It is likewise conceivable that the organic processes in the soil on which epidemics of cholera depend may be effectually checked by an excess of subsoil water or by a want of material. Micro-organisms have been divided into two classes: anaerobe and aerobe. If now we have to deal with an organism which requires oxygen for its existence (aerobe), it is not difficult to understand how the excess of water might deprive the soil of the necessary proportion of air. The more the pores were filled with water the less air would be contained in the soil. In heavy clay soils the water drives the air completely out, and thorough desiccation would be required to replace all the air. Klebs and Tommasi-Crudeli have already discovered a micro-organism which flourishes only in a moist soil containing air—the bacillus malariæ.

(*To be continued.*)

ON THE PATHOLOGICAL IMPORTANCE OF FLEXIONS OF THE UTERUS.

BY G. ERNEST HERMAN, M.B. LOND.,
OBSTETRIC PHYSICIAN TO THE LONDON HOSPITAL,
LECTURER ON MIDWIFERY, ETC.

(*Concluded from p. 730.*)

LASTLY, there are some clinical points mentioned by Dr. Hewitt as to which I can only say that my experience is not like his; and leave it to those interested in the subject to observe for themselves and form their own opinions. Dr. Hewitt has no recollection of seeing any case of severe dysmenorrhœa in which the uterus was "in anything approaching a straight condition." Among the 100 nulliparous women whose cases are tabulated in my first paper, I found five whose menstrual pain was so severe as to lay them up, and whose uteri presented no appreciable curve. Vedeler, out of 100 patients who suffered great pain at the menstrual period, found eight in whom the uterus was quite straight. In the twenty-third volume of the Obstetrical Transactions, which contains my paper already referred to, will be found a paper by Godson, describing four cases of severe dysmenorrhœa, with sterility; in one of these it is stated that there was no anteflexion, and in another that there was anteversion. It is not necessary to multiply illustrative quotations, for I have no doubt that anyone who has the opportunity of seeing many cases of dysmenorrhœa, and will pay attention to the shape of the uterus, will soon come to the conclusion that Dr. Hewitt's experience is in this respect quite exceptional.

Dr. Hewitt also regards as erroneous my statement that the cradle pessary will not straighten the uterus. But the only positive assertion that he makes is that the instrument is "of very great assistance in straightening the uterus and relieving dysmenorrhœa." I would ask those interested in the subject to examine carefully either by vaginal and hypogastric or by rectal and hypogastric palpation the shape of the uterus before and after the insertion of a cradle pessary. In the majority of cases they will find no appreciable difference. The position of the organ will be changed, its cervix being pulled forwards, and its body tilted a little back, but its shape will not be altered to any definite extent. A comparison of the measurements of the uterus and those of the cradle pessary will show that it is impossible for the cradle pessary to straighten the uterus by direct upward pressure on the body of the organ.

Another point as to which all that I can say is that my experience and that of others is different from Dr. Hewitt's, is this—that he has never seen retroflexion without symptoms, and only exceptionally without dysmenorrhœa. I submit that this may possibly be because he has only examined patients who came to him for uterine troubles. In my second paper I have mentioned that out of eighty-five cases of retroflexion, the notes of which I examined for the purpose of that paper, I found menstruation painless in twenty-one. There was painful menstruation not relieved by straightening the uterus in fourteen, and relieved without straightening the uterus in eleven—that is, twenty-five cases in which the dysmenorrhœa was proved not to depend upon the retroflexion. In all, forty-six cases out of eighty-five in which retroflexion did not cause dysmenorrhœa.[1] I do not think it needful (although there are many whom I might cite) to quote the statements of others on this subject, because retroflexion is a common condition, and anyone with a sufficiently large clinique can ascertain for himself whether Dr. Hewitt's experience holds good of all cases.

4. *The Effect of Treatment.*—I agree with Dr. Hewitt in thinking that the application in practice of the mechanical theory of uterine pathology is the great test by which it must be judged. We may rely upon it that if it be constantly found that straightening the uterus cures cases which cannot be cured in any other way, then treatment having for its object the straightening of the uterus will continue to be practised, no matter how faulty the explanation of the production and cure of symptoms may seem to be. That a line of treatment of which straightening of the uterus forms a part proves successful in the hands of Dr. Hewitt and others, I do not for a moment question; but it has yet, in my opinion (and I am not alone in thinking so), to be demonstrated that the straightening of the uterus is the essential part of the treatment, the *sine quâ non* of benefit. The cases which give the most striking presumptive evidence in favour of the theory are those of retroflexion with congestion. It is a frequent experience that in such cases the introduction of a pessary which raises the uterus into the axis of the pelvic inlet, and thereby necessarily removes the flexion, is followed by rapid disappearance of all the symptoms. Dr. Hewitt alludes to these cases, and to his mind the good that is done comes simply from the unbending of the uterus. The explanation of these cases that appears to me to be the correct one is that the congestion depends upon pressure of the veins in the broad ligament against the utero-sacral ligaments. As this paper is quite long enough already, and as I have elsewhere discussed the matter, I shall not here state the reasons in favour

[1] Dr. Hewitt quotes me incorrectly, as saying that of 138 cases of backward displacement under my care there was dysmenorrhœa more or less severe. I expressly stated that in forty-four of these menstruation was painless. Besides this, Dr. Hewitt has taken no account of the number of cases in which dysmenorrhœa was *not* relieved by straightening the uterus, and *was* relieved although the flexion persisted.

Digitized by Google

of my own view, but merely set forth the reasons which make me think that the unbending of the uterus is not the *sine qua non* of success in treatment. First, there are cases in which the same symptoms are present, and these symptoms are relieved by the same treatment—(i.e., the raising of the uterus so that it lies in the axis of the pelvic brim), but there is no flexion, the uterus being retroverted not retroflexed. Secondly, there are cases of retroflexion in which all the symptoms are removed by a pessary which simply pushes up the uterus but does not straighten it. These are cases in which congestion is absent (because when the uterus is congested, it is generally tender, and the presence of a pessary directly upon it cannot be borne), but the flexion in many such is acute. Thirdly, there are cases in which, after cure in the manner described, as Dr. Hewitt would put it, by unbending the uterus, the flexion returns as soon as the pessary is left off, but not the symptoms. These cases are not found unless they are looked for. It has been my custom when I removed a pessary from a patient whom I had treated by causing her to wear it to ask her to come in three months and tell me how she was. Many patients who feel well and think themselves well do not do this; but a few have done so, and in some of these I have found what I have mentioned; the flexion is as acute as ever, but the patient is quite well. On account of his quaint way of putting it, I may quote Fritsch.[2] "One not seldom sees patients who come back months or years after the removal of the pessary, full of gratitude for their cure. We congratulate ourselves on having definitely cured retroflexion, but on examination again we meet the old retroflexion!" In these cases it is clear that the bending of the uterus cannot have been the cause of the symptoms. There are thus a large number of cases of retroflexion in which the success of treatment is not consistent with the view that the flexion is the essential cause of the symptoms; and the cases which are consistent with this view can be otherwise explained.

Dr. Hewitt has written a good deal on the relation of malnutrition to flexion of the uterus. His argument, as I understand it, is this: he sees many patients who are badly nourished, and whose uteri are soft and bent. By diet, regimen, and medicinal treatment he builds up the general health, and at the same time, by positional treatment or by pessaries, he corrects the assumed malposition of the uterus. The result is that the patient gets well, and Dr. Hewitt attributes this benefit to the straightening of the uterus. But it is such a common thing for patients who are badly nourished to recover when they are well-fed and kept under a sanatory regimen, that unless we can separate the effect of the local treatment from that of the general treatment, such cases to my mind prove nothing. Dr. Hewitt says that I repudiate the treatment of dysmenorrhœa by bougies. On the contrary, I think it most efficacious, and frequently use it. But my experience is different from that of Dr. Hewitt, in that I do not find it produce any appreciable permanent alteration in the shape of the uterus. Dr. Hewitt says, "That the bougie treatment does straighten the uterus, and that the straightening is one which lasts for a certain time, is incontestable. How long its effect remains will no doubt vary in different cases." In this I quite agree; but its bearing on the question whether flexion is the cause of pain depends on what the "certain time" is during which the bougie removes flexion. I think it is a few minutes at longest. Even were it indisputable that dilatation with bougies always and permanently diminished the amount of bending, I do not think it would from that alone follow that the flexion was the cause of the menstrual pain. For dilatation will also cure menstrual pain in patients whose uteri are perfectly straight. In cases cured by the same remedy the presumption is, until the contrary has been shown, that the condition removed by the remedy is the same in them all; and the flexion is not a condition present in all.

Dr. Hewitt thinks it unreasonable to deny that the vessels in the uterine wall undergo compression when the uterus is bent. It is possible that there may be compression to a slight degree, but the numerous cases that are met by all who look for them of acute flexion without any symptoms whatever prove that the very slight compression on the one side and tension on the other that uterine flexion may produce does not, when the uterus is otherwise healthy, exert any influence on the circulation through the organ. The proposition that it does so is, so far as I can see, pure theory, put forward to account for certain clinical phenomena which can be otherwise explained.

If it were possible to base any argument on the results of treatment by stem pessaries, such an argument, I think, would be most cogent. There can be no question that while a patient is wearing a rigid intra-uterine stem the uterus must be straight. Stem pessaries have been familiar to the profession for half a century, and still they have not come to be widely used. In alluding to this in my former paper I said that if these instruments did good they must before this have been generally recognised as instruments of undoubted efficiency. Dr. Hewitt thinks "the stem treatment would be largely employed but for the known liability to danger." He must be aware that whenever this subject comes under discussion at the Obstetrical Society those gentlemen whose names are identified with special forms of this instrument get up and say that they *never* see any bad results. It is idle to argue on this question. What is wanted, is for those who have used this instrument largely to publish *the whole* of their cases so treated, and to publish the result *in every case*, giving the symptoms for the removal of which the treatment was undertaken, the condition during the wearing of the stem, and the state of the patient as to symptoms and shape of uterus some months after leaving off the stem. When we can refer to an exact statement like this instead of to the vague assertions that are now made *pro* and *contra* this instrument, much light will be thrown not only on the effects of stem pessaries, but on the question of flexions generally. Till this has been done, all that can be said is that we have no scientific evidence to show either that the intra-uterine stem does good, or what is the amount of risk that attends its use.

I would now, to prevent misconception, state briefly my opinions on the subject.

Anteflexion is one of the natural shapes which the uterus may have. It is present in the majority of nulliparous women. It is present most often in early life, but tends to disappear as the uterus takes on functional activity. For this reason, in cases in which deficient development is associated with imperfect performance of function, anteflexion is especially often found. There is no evidence that the anteflexed condition in itself causes any hindrance to the performance of function. It is possible that anteflexion may produce symptoms, but it has never been proved, and if it be so, it is certain that such cases are exceedingly rare, and we have at present no means of identifying them. In a healthy state of the pelvic organs it is rare for the uterus to be retroflexed, but this occasionally happens, and causes no symptoms. When the supports of the uterus become weakened and prolapse begins, it is common for the uterus, as it sinks, to become retroflexed. Retroflexion is in such cases found accompanied with the usual symptoms of slight prolapsus, which are not modified by it. These cases form the majority of those in which retroflexion, because it is removed by the treatment—viz., the giving of the needed support—which removes the flexion, appears to be the cause of symptoms. But the relief to symptoms follows equally from the treatment whether the flexion is removed or not. The disposition of the musculo-peritoneal bands behind the uterus (utero-sacral ligaments — sometimes called the musculi retractores uteri) is in a few cases such that when the body of the uterus sinks between them, the veins which return the blood from the uterus are pressed upon, the return of blood obstructed, and congestion of the uterus is the result. In such cases striking relief quickly follows the raising of the uterus, so that its veins are no longer pressed on; and this relief is most striking when the uterus is so much raised that it falls into a position of so-called anteversion. It is probable that many symptoms have been attributed to flexions which depend simply on the general health of the patient, and would have been cured by the treatment adopted if the shape of the uterus had been quite ignored.

West-street, Finsbury-circus, E.C.

[2] Die Lageveränderungen der Gebärmutter, S. 123.

THE POLLUTION OF THE THAMES.—At a meeting held at Woolwich on the 22nd ult., for the purpose of condemning the state of the river Thames, and suggesting remedies for its improvement, the Right Hon. Lord Forbes, who presided, stated that the A B C system of purification seemed to him to be a perfect solution of the difficulty of dealing with the sewage of large towns, and that there was no reason why the system in operation at Aylesbury should not be applied to London.

TWENTY-FIVE CASES OF ABDOMINAL SECTION.

(SECOND SERIES.)

BY EDWARD MALINS, M.D.,
OBSTETRIC PHYSICIAN TO THE GENERAL HOSPITAL, BIRMINGHAM.

IN this list the following conditions are represented :—

Removal of uterus with ovaries for fibroid	1
Removal of ovaries and tubes for fibroid	1
Ovarian cystoma	7
Chronic ovaritis	6
Chronic pelvic peritonitis	4
Dermoid cyst of ovary	1
Pelvic abscess	2
Pyosalpinx	1
Double cyst of broad ligament	1
Exploratory	1

In this series there has been one death only. In a girl, aged seventeen, with chronic pelvic peritonitis, there had been persistent hæmorrhage for seven months. The left ovary and tube were found adherent to the side of the uterus, and the opposite ovary adherent to its tube. Both ovaries and tubes were removed, and the pelvis drained. She did remarkably well until the eleventh day, when she was bright and cheerful. Having eaten a good tea, and while reading, she suddenly screamed and died in a few minutes. At the post-mortem, carefully made by the pathologist, there was no marked structural change, and the conclusion was drawn that death was due to fatty embolism.

The ovarian cystomata varied from thirty-three to eleven pounds in weight. All the patients recovered satisfactorily. One case was complicated with a large fibroid of the uterus. Two cases of pelvic abscess were opened, the pelvis washed out with warm water and drained. One contained sixteen pints of fetid pus. Both did well.

In the six cases of chronic ovaritis the ovaries and tubes were in each instance more or less adherent, and the ovaries generally enlarged—the average weight being 140 grains. In the four cases of chronic pelvic peritonitis the ovaries and tubes were also removed, adhesions broken down, and the pelvis washed and drained with success, except in the case above-mentioned.

In the removal of the uterus with ovaries there was a large fibroid which had been the source of much pain and metrorrhagia for eight or nine years; the stump was secured by a serre-nœud and treated with iodoform. The patient made an excellent recovery, and has since reported herself as being in good health. The pyosalpinx had the ovary and tube of the left side intimately adherent, the tube dilated and tortuous, containing two drachms of thick pus; it was separated without bursting and not drained; the opposite ovary and tube were enlarged, thickened, and adherent, and were also removed.

A case of double cyst of the broad ligaments was exceptional in character, being filled with about ten and twelve ounces respectively of dark tar-like fluid; these were shown at a meeting of the Obstetrical Society on October 1st. One explanatory examination is instructive and interesting. A girl, aged nineteen, attended the out-patient department for several months, complaining of severe abdominal pain, worse at the menstrual epochs, and causing pain in micturition and defecation. Nothing abnormal could be found in the rectum or bladder; the uterus and ovarian regions were very sensitive. She became an in-patient for five weeks, and was subjected to a variety of treatment and discharged. Several weeks later her mother came and begged for something more to be done for her as the pain was intense at times. She was readmitted, and the abdomen opened. I examined the ovaries, which were intact, and therefore not removed. Nothing wrong could be found elsewhere in the pelvis; it was washed out and the wound closed. The pain never recurred and the patient got quite well. Some weeks later she returned to say that her health was better than it had ever been, and to express her thanks for the operation.

The majority of the cases were done in the General Hospital under the conditions expressed in the record of the previous series. The amount of success justifies the conclusions then drawn that abdominal sections may be successfully performed in any institution with proper precaution and care.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

HOSPITAL FOR SICK CHILDREN.

CASES OF MALFORMATION OF THE EXTERNAL ORGANS OF GENERATION.

(Under the care of Mr. JOHN H. MORGAN.)

CASE 1. *Hypospadias; Left Scrotal Hernia; Absence of Right Testicle.*—C. B—— was the twelfth child of parents whose other children were healthy and well-formed. About ten weeks before his birth the mother had a severe fall. The penis was short, and was bound down on each side and below by short bands of skin. The glans was exposed and the prepuce was normal. There was a depression for the meatus at the end of the glans which was not patent, the opening of the urethra being situated at the base of the penis. The skin of the scrotum was natural, and a testis, followed by a hernia, had descended on the left side. There was no testis in the right half of the scrotum, which consequently appeared smaller than the other. The condition gave the parts a great resemblance to those of a female.

CASE 2. *Deficient Development; Non-descent of Testes.*—A. F——, aged four years. Three elder children, all naturally formed, have died of various complaints. This child appears idiotic, cannot talk, and understands very little. The penis is very small and attenuated. It is placed higher than usual, as if there were some deficiency of the pubic symphysis. The prepuce is long, the scrotum very slightly indicated, the testis on each side having descended into the lower part of the inguinal ring, but not into the scrotum.

CASE 3. *Hypospadias; Hydrocele on Left Side; Non-descent of Right Testicle.*—F. M——, aged one year. No family history of hereditary deformity. The penis is very short, and exhibits the usual condition of hypospadias, the urethral orifice being situate at the base of the frænum. The left testis descends into the scrotum, accompanied by a large hydrocele; the right cannot be felt in the scrotum or inguinal canal.

CASE 4. *Congenital Penile Fistula.*—W. S——, aged three years and a half. No family history of deformity. The boy is healthy and well-made. The meatus is natural, the prepuce long. A probe passed through the meatus issues at an orifice midway along the under surface of the penis, the edges of which are thin, and resemble those of a meatus. From the orifice in the external skin, which corresponds to this opening, a probe will also pass along beneath the skin of the prepuce, so that there is a double deformity, and micturition is performed through both openings.

CASE 5. *Hypospadias; Displacement of Urethral Orifice to Left Side.*—F. P——, aged seven months. This child has an ordinary condition of hypospadias as regards the depression for the meatus, but instead of being situated below, the opening of the urethra is situated at the left side of the penis. The median raphe of the scrotum is continued up into the outer skin of the penis along its lower surface, and the urethral opening is placed on the left side of the corona.

CASE 6. *Absence of Right Scrotum.*—F. C——. This boy has an elder brother who is normally formed. He was born with the following condition of parts. The left half of the scrotum is natural, and the testis is of proper size and in the usual position. There is no sign of any scrotum on the right side, nor is there any evidence of a median raphe. The right testis can be felt beneath the skin which is between the scrotum and the thigh. It is of normal size and movable. There is no hernia.

CASE 7. *Congenital Cyst in Prepuce.*—T. W——, aged two years. When three weeks old, a small spot was noticed on the under surface of the prepuce. It was at first the size of a pin's head, but has continued to grow larger. When seen at the hospital, a small transparent cyst the size of a cherrystone, and containing clear fluid, was found upon the under surface of the prepuce, which

Digitized by Google

was slightly adherent to the glans. The walls of the cyst were thin, and the margins not hard or sharply defined. It was removed with scissors, and did not recur.

ST. LEONARDS HOSPITAL, SUDBURY, SUFFOLK.

THREE CASES OF FRACTURED PATELLA; ONE TREATED BY BACK SPLINT, THE OTHERS BY WIRE SUTURE; REMARKS.

CASE 1. *Transverse Fracture; Back-splint with Traction; Recovery, with good Movement.* (Under the care of Mr. Lynch.)—J. T——, an engineer, aged forty-four, a temperate man. On December 26th, 1881, in getting over a stile he slipped, reached the ground with his right toe, tried ineffectually to save himself, and struck the ground with his right knee. As he did so the knee "went off like a gun," and the leg became powerless. He was admitted on the 31st, when a transverse fracture was found running through the middle of the patella. The effusion was not excessive, but the separation was very great.

The treatment was by a back-splint, figure-of-eight bandage and pads, and elastic springs on either side. These springs were attached by extension plaster to the thigh, and by their other ends to tapes which buckled under the sole of the foot. They were powerfully stretched before buckling—the patient estimated their pull at about thirty pounds,—and they acted very efficiently in bringing the fragments of the patella nearly into apposition. This treatment was continued for six weeks, after which the limb was cased in a plaster-of-Paris bandage, and the patient was allowed to get about with crutches. He was then discharged from the hospital. At the end of nineteen weeks the bandage was removed, and he returned to work, able to earn his full wages. The stiffness of the limb gradually wore off, but three or four months elapsed before he was able to kneel.

CASE 2. *Transverse Fracture; Fragments United by Wire Suture; Recovery, with good Movement.* (Under the care of Mr. Lynch.)—W. S——, a carter, aged thirty-three, of stout build, and a free liver, jumped off the shaft of a cart on April 25th, 1884. He reached the ground with the left foot first, slipped on a loose stone, and in falling struck the ground with his left knee, which, on rising, he found to be useless. He was admitted in the hospital on April 28th. The left knee then measured two inches in circumference more than the right, and a transverse fracture ran through the centre of the patella, the fragments being one inch apart. It was thought advisable to allow time for the effusion to subside.

On May 5th, eleven days after the accident, there was only half an inch of difference between the size of the knee-joints, and the operation for uniting the fragments was performed according to Professor Lister's instructions. The spray was used, and the wound dressed with gauze and mackintosh in the usual way.

The patient was very sick after the operation; evening temperature 100°, and on the 6th 100·2°. On the 7th, 8th, and 9th it was 99°, both morning and evening; then fell to normal, and so remained. The limb lay in a MacIntyre's splint, and was dressed under spray on the second, fifth, and ninth days after the operation, on the fourteenth day with red lotion. The drainage-tube was withdrawn at the second dressing. On the 26th passive motion was made, and no pain was experienced on bending the knee. On June 2nd, exactly four weeks from the date of the operation, the patient got up and moved about with crutches, but he was not allowed at first to put the foot to the ground. Crutches or sticks were used for two weeks; and in a fortnight afterwards he was discharged, after a residence in the hospital of two months. He began light work six weeks later, and a week afterwards was in full work at harvest. He could kneel in about fourteen days after he left the hospital. The wire uniting the bone causes some pricking sensation when he kneels or walks down an incline. This probably arises from insufficient hammering of the wire to the bone.

CASE 3. *Transverse Fracture; Union of Fragments; Suture; Rapid Recovery.* (Under the care of Mr. Ogier Ward.)—C. H. C——, a labourer, aged sixty, a temperate man, in 1879 was thrown from a horse and broke his left thigh near the knee. In 1881 the same bone was broken in the upper third through a fall from a cart. He quite recovered the use of the limb but there is some shortening. On Aug. 7th, 1884, he fell from a ladder on to his left knee, and found he could not walk. He was admitted into hospital on Aug. 8th.

On Aug. 10th, with the permission of the medical officers, Mr. Ogier Ward performed the operation for bringing the fragments of the patella together. The separation of the fragments, which had previously been about half an inch, became very marked under chloroform. There was much swelling and extravasation of blood, but it had not been thought necessary to wait till the effusion into the knee-joint had subsided spontaneously, for Prof. Lister has pointed out that delay in operating, on account of effusion, is productive of no good result, and the after-progress was certainly greater in this case than in the second of the above cases. On incision a quantity of dark blood escaped, and the broken surfaces were found thickly covered with coagulum. The fracture was transverse at the junction of the upper and middle thirds. The capsular tissues had been torn off the lower fragment, but remained attached above, and hung like a flap between the fractured surfaces, effectually preventing their apposition. There was also an oblique displacement of the upper fragment, which, when the muscles were lax, partly overlapped the lower. This obliquity appeared to be due to the unequal contraction of the extensor muscles, probably in some way connected with the old fractures of the femur. The spray was employed, and after wiring the fragments, the joint was syringed full of carbolic glycerine (1 to 12), and the patella and parts near were freely powdered with iodoform. The dressing consisted of protective, covered by one piece of damped carbolic gauze, with a plentiful supply of salicylic wool outside. The limb was placed on a MacIntyre's splint. Evening temperature 100·2°; pulse 80; no pain or sickness. On the next day the temperature was 99·2°, and the pulse 78. The dressings were changed, and the anterior drainage-tube removed. On the sixth day after the operation the dressings were renewed and the posterior tube discontinued. Two days later red lotion was used. The temperature fell to normal on the fourth day.

On Sept. 1st, twenty-two days after operation, passive motion was begun, and the patient was allowed to get up and use crutches, keeping his foot off the ground at first. On Sept. 18th, six weeks from the date of admission to the hospital, he was discharged, sufficiently cured to walk without a stick, and able to kneel. He was able to resume work on Oct. 6th.

Note.—On Oct. 3rd all three men were present for examination. Case 1. Three years since his accident. The union is remarkably good; there is not more than three-eighths of an inch separation. Except that he cannot flex the knee beyond a right angle, the patient has the perfect use of his limb. Case 2. Five months since the fracture was sustained. Union is of course perfect, as are also all movements of the joint. Case 3. Barely two months have elapsed since the injury; there is a little stiffness in kneeling and in flexing the limb: this is rapidly wearing off. The points of contrast are pretty effectively brought out in the following table:—

—	Confined to bed.	Crutches or sticks.	Further delay in resuming work.	Total time lost.	Could kneel after the accident.
Case 1	6 weeks	19 weeks	2 weeks	27 weeks	9 months
Case 2	4 weeks	2 weeks	7 weeks	13 weeks	6 weeks
Case 3	3 weeks	2 weeks	3 weeks	8 weeks	5 weeks

Remarks by MR. OGIER WARD.—There are several points of note. 1. The treatment of fractured patella by mechanical methods is tedious and difficult, not only in respect to the time required for success, but in the constant attention which the appliances require, and in the very considerable annoyance which they cause to the patient. By operating with strict antiseptic precautions the patient suffers no pain, he is confined for too short a time to bed to allow of injury to his health, while the labours of the medical man and nurse are very considerably lightened. It is also allowable to feel a well-grounded confidence as to the result, very different from the anxiety experienced from first to last in a case treated by mechanical means. 2. Such union as was obtained in Case 1 is by no means universally found persisting three years after the accident, as by this time a gradual stretching of the fibrous bond of union has very frequently occurred; but no doubt the early treatment in this case was

Digitized by Google

particularly thorough. I question whether in Case 3 the mechanical mode of treatment would have been successful, considering how the capsule and other tissues were squeezed between the fragments, and I venture to suggest that some such complication may in many cases of ununited fracture of patella cause the fragments to gradually fall apart as time goes on. 3. If we consider the serious loss to a working man and his family represented by twenty-seven weeks of enforced idleness, I think we are fully justified in reducing that time by quite one-half, by undertaking an operation where the results are so satisfactory, provided always we have a just confidence in our mode of treatment. It is so common nowadays to read of cases which become septic "in spite of strict Listerian precautions," that it is no wonder surgeons are not all disciples of Lister. I am sure those who have seen antiseptic surgery as practised in Germany will admit that we in England are, as a rule, very far behind. I can only say that were my own patella fractured I know more German than English surgeons whom I would trust to operate upon me. There is one important detail in the operation which in the above cases gave rise to considerable difficulty. It is not alluded to by Professor Lister, to whom, perhaps, his adroitness renders the matter a trifle. To pass the wire from the external to the fractured surface of the patella is easy enough, but the second threading, from the fractured to the external surface, is difficult, for, on withdrawing, the point of the bradawl the hole is instantly obliterated, and the point of the wire searches blindly for it in the interstices of the broken bone. In addition, unless the separation be great, or the limb be flexed, which is scarcely advisable, there is only a trench about half an inch wide in which to manipulate. I have, therefore, had a trocar and canula made, the former fitted with a bradawl point, on withdrawing which, the cannula will be left projecting upon the fractured surface, and be easily found by the point of the wire. It seems advisable, as a rule, to wire the more difficult fragment first.

COLONIAL HOSPITAL, SAN FERNANDO, TRINIDAD.

IMPERFORATE RECTUM; CURE.

(Under the care of Mr. R. H. E. KNAGGS.)

A MALE infant, five days old, the child of healthy negro parents, was admitted on Sept. 6th, having never passed an evacuation and suffering acutely from abdominal distension. The little finger introduced per anum was arrested about half an inch in by a firm and complete occlusion. Nothing definite could be distinguished beyond, and palpation gave no fluctuation. A fine aspirator needle was passed through the centre of the cul-de-sac in the rectal axis, and on withdrawal was found to contain meconium. A large trocar was now introduced, and a copious flow of offensive meconium followed its removal. The cannula was left *in situ* and retained with a large pad of carbolised tow and a T-bandage. All urgent symptoms were immediately relieved. The tube was removed twenty-four hours after introduction, and the motions soon became more natural. The case proceeded with uninterrupted success, and the little patient was discharged cured six days after admission. The little finger could be passed through the obstruction fairly easily.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Treatment of Unreduced Spontaneous Dorsal Dislocation of the Hip.—Cirsoid Aneurysm of Foot.

THE first ordinary meeting of this Society was held on the 28th ult., Dr. George Johnson, F.R.S., President, in the chair. The President referred to the improvements which had been effected, at considerable cost, in the drainage of the house in which the Society met; also the better lighting, increased space, and the new lavatory, which had been provided.

Mr. WILLIAM ADAMS read a paper on Excision of the Head of the Femur in a case of Unreduced Spontaneous Dorsal Dislocation occurring during Fever. The case was an example of spontaneous dislocation of the head of the femur on the dorsum ilii, occurring during the progress of rheumatic fever in a boy eleven years of age, and as the limb remained in a contracted and useless condition, the head of the femur was excised on March 29 h, 1882. This operation had been first performed in a similar case by Dr. H. G. Rawdon, of Liverpool, on July 16th, 1881, and published in the *Liverpool Medico-Chirurgical Journal*, January 2nd, 1882. In Mr. Adams's case the patient was admitted into the Great Northern Hospital on March 4th, 1882. After two unsuccessful attempts at reduction, having previously divided the adductor longus tendon, Mr. Adams excised the head of the femur by making a T-shaped incision with the long arm two inches and a half in length directly over the head and neck of the bone, and the small arm one inch in length, transversely over the head of the bone, which was at once exposed. The head of the femur was uncovered by capsular ligament, and the articular cartilage was in a healthy condition. It was found that the capsular ligament had been ruptured, and the torn margins of the rent passed on either side of, and closely embraced, the neck of the bone. After dividing the margins of the capsular ligament the operator passed his small subcutaneous saw to the neck of the bone, and cut through it a little below the margin of the articular cartilage. The detached head of the femur was then drawn out of its position after some slight adhesions had been cut through. The round ligament preserved its normal connexion with the head of the bone, and was adherent to the articular cartilage, having been divided with the saw a little below the head. The wound progressed favourably without much suppuration, and on June 1st was completely closed. On June 14th the patient was allowed to walk on crutches, and on October 1st without crutches. The limb was perfectly straight, and the movement at the hip-joint was free in all directions. The author observed that in all the cases of spontaneous dislocation which had fallen under his observation the head of the femur had been dislocated on to the dorsum ilii. The cases were arranged in three classes:—1. Dislocation occurring during the progress of fever. 2. Dislocation occurring in cases of paralysis, generally infantile, but occasionally in the adult. 3. Dislocation occurring in the first stage of hip-joint disease without suppuration. Excision of the head of the femur in its simplified form, as above described, the author believed would be found applicable to all these cases unless sufficient freedom of motion be obtained by tenotomy and passive movements. He also thought it might be applicable to some cases of fibrous ankylosis of the hip after disease where the limb remained contracted, as free motion is seldom obtained by simply dividing the neck of the bone. The cases of dislocation of the hip brought before the Society by Mr. Morris were alluded to, and also the case published in St. Thomas's Hospital Reports, by Sir Wm. Mac Cormac, in which the head, neck, and great trochanter were excised in a case of unreduced traumatic dislocation of the hip into the thyroid foramen. The firm adhesions, and in some cases the new bone thrown out in cases of traumatic origin as the result of the inflammation following the injury, distinguished these cases from those of spontaneous dislocation occurring during the progress of fever, or in cases of paralysis which had chiefly fallen under his observation. In reply to Mr. Hulke, Mr. Adams justified the removal of the head of the bone by the results he had obtained; moreover, every other means had failed, and the leg was contracted and perfectly useless.—Mr. HENRY MORRIS also exhibited to the Society the case of the man with unreduced dislocation which had been referred to in the paper read by Mr. Adams.—Mr. ARTHUR E. BARKER referred to a case which was admitted into University College Hospital. The boy had sustained spontaneous dislocation in the third week of typhoid fever, when Mr. Barker first saw him; the hip was very much deformed, and there was a moderate degree of pain. The marked deformity presented all the appearance of a dorsal dislocation. On examination the head was found to be one inch and three-quarters above Nélaton's line. The boy was put under the influence of chloroform, when the ligaments as well as the muscles were found to be greatly contracted. By Bigelow's method the head was got into the acetabulum. After this had been done the limb could not be fully extended, but by diligently persevering in passive movements the powers of progression gradually became almost natural. He thought that in all cases of acute synovitis serosa the manipulative movements of strong flexion with eversion and circumduction would be able to reduce the dislocа-

Digitized by Google

tion. He questioned whether it was necessary to resort to so severe a procedure as excision in any case. In the majority of instances it was fair to assume that the acetabulum was intact. If reduction could not be effected by Bigelow's method, it would probably be sufficient to incise the capsule, and then reduce the dislocation. It would probably never be necessary to divide the whole of the capsule, and even if this had to be done, the ultimate result could hardly fail to be better than in cases where the head of the bone was excised.—Mr. W. HULKE agreed with the views expressed by Mr. Barker. It should be remembered that the accident was a relatively recent one in Mr. Adams's case. The boy, no doubt, ran a certain amount of risk, and as it was an abscess had formed. He had had several instances of spontaneous dislocation under his care. In one the right hip-joint was affected in the course of rheumatic fever, in this instance he had no difficulty whatever in reducing the dislocation. He admitted that a recurrence of the dislocation might take place. It might be doubted whether the result in Mr. Adams's case was better than if an excision had not been done.—Mr. RICHARD BARWELL had seen several instances of so-called spontaneous dislocation. Reference was made to two cases. One was that of a young lady who had a severe attack of typhoid fever, after recovery from which it was found that the left hip was dislocated. Mr. Barwell saw her first fifteen months after the fever. The method of extension by weight and pulley, and Bigelow's method, did not succeed in reducing the dislocation. Passive movement was persisted in, and three years later the walking powers were good, and there was but half an inch of shortening. A second case, in which considerable movement was obtained, with rather more shortening, was briefly narrated. He agreed with the opinion of Messrs. Hulke and Barker.—Sir WILLIAM MAC CORMAC thought that all surgeons would first attempt to reduce the dislocation in the cases under consideration. His case, mentioned by Mr. Adams, was one which owned a rheumatic origin. The patient was a sailor who had sustained a thyroid dislocation of the hip-joint twenty months before he was first seen. Tenotomy and other means had failed to reduce the dislocation. When the operation of excision was in process of performance the acetabulum was found to be very shallow, and thus the impossibility of reduction was accounted for.—Mr. R. W. PARKER considered the operation performed by Mr. Adams as not altogether justifiable. He related briefly a case of acute necrosis of the tuber ischii in which the inflammation spread to the hip-joint; there was spontaneous dislocation of the head of the femur on to the dorsum ilii. In this instance a good result was obtained by the formation of a false joint. He had seen no case of dislocation associated with infantile palsy, and he could not conceive how the paralysis alone would account for dislocation. In some cases of infantile palsy the capsule becomes stretched and loose, and an apparent dislocation might result. Further, he had never seen an instance of Mr. Adams's class of spontaneous luxation.—Mr. SPENCER WATSON spoke of the severity of the case on which Mr. Adams had operated. He regarded both Dr. Rawdon's and Mr. Adams's cases as of an altogether exceptional nature.—Mr. BOWLBY said that the paper had made no mention of pyæmia as a cause of spontaneous dislocation. In one case of this sort the acetabular cartilage was found to be normal after death. A lad, aged nine years, had been under Mr. Langton's care for spontaneous dislocation. The dislocation was reduced and the limb extended on a long splint, but what the ultimate state would be could not yet be determined.—Mr. HENRY MORRIS said no one could fail to congratulate Mr. Adams on the result which had been obtained. Granted that reduction was impossible, the question arose whether any operation was advisable. He could not help believing that by dint of time and perseverance good results might be obtained. An unreduced dorsal dislocation which resisted all other measures of relief might be treated by subcutaneous osteotomy; by this neat and simple operation we might alter the deformity and correct the angle at which the limb was placed. The surgeon endeavoured to get bony union of the section only at a different angle, so that parallelism of the limb and fair powers of movement should result. Reference was made at some length to a paper published by him in the forty-fifth volume of the Society's Transactions. In cases of paralysis in the adult operation would be out of the question; for such cases might be examples of Charcot's disease. Mr. Stanley had written a paper in the twenty-fourth volume of the Society's Transactions where there was double dislocation of the hip-joint, which was probably a case of Charcot's disease. In instances of traumatic disease, where a considerable degree of fibrous ankylosis obtained, he believed that subcutaneous osteotomy would also prove of value. A case of long-standing disease with very great flexion was related, in which he had excised the head and neck of the bone. It was found that a small sequestrum existed in the head of the bone, which was surrounded by some rarefied osseous tissue. Here the limb was made sufficiently straight to allow of good movements of progression; the man, it must be remembered, was fifty-five years of age, and bore the operation remarkably well.—Dr. RAWDON said it was now three years since the operation was done in his case, and the limping had come on within the last year.—Mr. ADAMS, in reply, agreed that the operation was not one that should be too lightly undertaken. He would not recommend the operation until all manipulative and other measures had failed. The operation was by no means a severe one. A case illustrating dislocation of the joint in the first stage of morbus coxæ was related where treatment by Thomas's splint had been adopted. The paper published in 1841 in the Transactions of the Medical and Chirurgical Society by Mr. Stanley showed that there were three cases in adults; one of these might have been an example of Charcot's disease. Mr. Adams advised not too much delay, because tilting of the pelvis and spinal deformity prevented good results. In the traumatic class of cases the first operation was performed by Mr. Sydney Jones. Excision of the head of the femur was resorted to after failure to reduce the dislocation by other means. The boy afterwards walked, jumped, and joined in all athletic games.

Mr. WALTER EDMUNDS read a paper on a case of Cirsoid Aneurysm on the Dorsum of the Foot, with remarks. The patient was a man aged twenty-nine, who had an aneurysm on the dorsum of the left foot. Pulsation could not be completely arrested by compression of the anterior tibial artery. Esmarch's bandage was applied, but without benefit. The aneurysm was dissected out, seven communicating vessels requiring ligature. The patient recovered. The various methods of treatment were discussed, and digital compression having failed, or being unsuitable, excision was recommended. An abstract of previously published cases of the disease was added.—Mr. W. HULKE had seen the case, and referred to the tortuous condition of the arteries. Pressure on the anterior tibial artery failed to stop the pulsation, but when proximal as well as distal pressure was resorted to pulsation ceased. In a case of aneurysm of the supraorbital branch of the ophthalmic artery he had found that galvano-puncture was very efficacious. He could not but believe that galvano-puncture was a less severe measure than dissecting out the sac in such cases.—Mr. RICHARD BARWELL inquired whether the case were one of true cirsoid aneurysm or one of sacculated aneurysm, with which a good many dilated arteries communicated. Aneurysms on the dorsum of the foot were very difficult to treat, and statistics as collected by him showed how fatal a disease it was.—Mr. EDMUNDS replied that the disease was not true cirsoid aneurysm.

CLINICAL SOCIETY OF LONDON.

Myxœdema.—Dislocation of Patella.—Bromide Eruption.—Nephrectomy for Sarcoma.

AN ordinary meeting of this Society was held on Oct. 24th, Sir Andrew Clark, Bart., President, in the chair. An interesting case recorded by Professor Bruns of Tübingen, bearing on the pathology of myxœdema and cretinism, was related by Dr. Felix Semon.

Dr. JAMES ANDERSON gave a short account of the clinical history of a case of Myxœdema. The patient was an unmarried woman, aged forty. She complained of swelling of the eyelids, which she had noticed to be gradually increasing for the past nine years. The patient was one of a family of nine, none of whom had shown any symptoms resembling hers. The patient's father died in old age; her mother died at fifty-seven, with hæmorrhage from the mouth and vomiting coffee-ground material. There was no history of gout or hæmophilia in the family. Up to the age of twenty the patient lived at home in Liverpool. Thereafter she was for twelve years nurse and maid in a family in Liverpool, and for the last eight years she had held a similar position in a family living in Kendal. She had always had a good home,

Digitized by Google

with plenty of fresh air and exercise, and freedom from anxiety or exposure. For the first twenty-three years of her life she enjoyed excellent health, when, seventeen years ago, she had two teeth extracted, the bleeding from which lasted twenty-four hours, and was very copious. She said she has never been well since. No marked symptoms, however, were noticed by those around her till twelve years ago. The patient presented the characteristic phases of myxœdema as described by Dr. Ord. The loose, baggy, almost translucent lids, the dry brawny cheeks and thick blue lips, with the swollen, red, expressionless hands, and deliberate speech and volition, make a group of symptoms which only the comparative rarity of the disease can have prevented from earlier recognition, and which, once seen, cannot be forgotten. The heart and lungs are sound, and the digestive system is somewhat defective. The molar teeth have crumbled away bit by bit; the gums are vascular and hypertrophied and bleed freely. The extremities are always cold, and the axillary temperature subnormal. The urine varies much in quantity; the total amount of urea is invariably deficient, only rising to half the normal amount, and frequently being as low as one-fourth; it contains neither sugar nor albumen. She has menstruated regularly from the age of fourteen. The amount has always been copious, but sometimes after the discharge has ceased it commences again, and may last for three weeks, leaving her very exhausted. With the exception of the deliberate speech, thought, and volition, there are only two points to be noted as to her nervous system: the first is the constant recurrence of a nervous restlessness, which she terms "fidgets"; the second is her ocular condition. She is slightly hypermetropic, but with the correcting lenses has perfect vision. Under atropine there is seen to be slight peripheral opacity of the left lens, otherwise the media are normal. In neither eye, however, is the retina normally transparent; a haze exists surrounding the vessels, especially in the neighbourhood of the disc. The appearances differ entirely from those of a past neuritis or retinitis, and, as has been said, do not interfere with perfect vision. Dr. Stephen Mackenzie kindly admitted her under his care at the London Hospital, and to him Dr. Anderson was indebted for detailed observation during her stay there. As regards treatment, the usual tonics seemed to have no effect whatever, either before or after admission. A fortnight after admission she was put upon half-drachm doses of tincture of jaborandi, which she continued till she left the hospital, three weeks later. Of objective improvement there was none, or almost none, but she expressed herself as feeling much better within a few days after commencing the jaborandi, and this subjective improvement was accompanied by a steady increase in the amount of urea excreted, which doubled itself during the period, and was at its maximum on her discharge from the hospital. Dr. Symington of Wolverton has since had her under his care for severe menorrhagia, and he states that she seems in very much the same condition as when she was last seen. The points of interest in the case seem to be (1) the history of commencement from a severe hæmorrhage, combined with the present hæmorrhagic tendency of the patient; (2) the occasional state of nervous restlessness, so apparently incompatible with the general character of the disease; (3) the retinal condition, which was peculiar, whether characteristic of the disease or not; and, lastly (4) the effect of jaborandi on the subjective condition of the patient, and on the amount of urea excreted by her.—Sir ANDREW CLARK inquired as to the state of the vascular system. He had never seen a normal circulation in cases of myxœdema.—Dr. ANDERSON replied that the heart yielded no signs of valvular disease, but its action was weak and the pulse was at times impercceptible at the wrist. In reply to Sir Andrew, he also stated that in his opinion the increase in the daily discharge of urea, which accompanied the administration of jaborandi was directly due to that drug and not to an alteration in diet.—Dr. FELIX SEMON referred to an account, which he had given before the Society last session, of the results obtained by Kocher from the removal of the thyroid gland in growing persons. The group of symptoms were stated not to appear when a part of the thyroid gland was left behind or an accessory thyroid gland existed. The fact that the cachexia strumipriva appeared in young individuals of incomplete development required to be supplemented by other facts before the full alliances with myxœdema and cretinism could be made out. Removal of the whole of the gland leads to arrest of the development of the length of the body, whilst the head continues to grow. It was hoped that the investigations of Kocher would throw light on the nature of cretinism and myxœdema, in both of which states the thyroid gland was involved; it was now probable that there were merely changes in degree between these three affections, and that the difference between them depended on the time of life at which the symptoms set in. Atrophy or degeneration of the thyroid gland was probably the cause of all the symptoms of myxœdema. What might be called the missing link in the proof of the causation of myxœdema and its allies had recently been supplied by Herr P. Bruns, Professor of Surgery in Tübingen, and which is published in the *Sammlung Klinischer Vortrage* of Professor Volkmann under the title of "Ueber den gegenwärtigen Stand der Kropfbehandlung." The case was that of a man still living, aged twenty-eight years, who had the thyroid gland completely extirpated eighteen years ago. A record of the operation was published at the time by Dr. Sick of Stuttgart, in the *Württemb. Med. Correspondenzblatt*, 1867, No. 25. Prior to and shortly after the operation the boy was bright and lively, but later on he changed in a remarkable manner. And although he retained the power of mental application and willingness for work, yet he had altered notably also in intellectuality. The man, now aged twenty-eight, has many of the characters of a dwarf and cretin; the conformation of the body is that of a boy, the greatest length being 127 centimetres. Nevertheless, the head is in every respect the size of that of an ordinary man; the facial expression is idiotic, and the features are much swollen, especially about the lips and lower eyelids. The hair of the head is scarce and thin, and there are but few hairs on the pubes, though the genitals are normally developed. Swelling of the tongue, palate, and tonsils exists to some extent. The breath sounds are normal, and the action of the heart is feeble; no enlargement of the spleen could be made out. The faculties of sensation and muscular power are preserved almost intact. Although until recently he was industrious, especially at knitting, yet now even this proof of a limited preservation of intelligence has passed away. The mental disturbances are confined to the exhibition of apathy. The visual and auditory powers are sensibly decreased in acuity. Commenting on this case and the results obtained by Kocher, and also by Schiff on a young cat, Dr. Semon thought there was sufficient evidence to prove the near relation of cachexia strumipriva to myxœdema and cretinism. The question of the exact connexion between absence of the thyroid gland and the groups of symptons which characterised myxœdema, &c., was also discussed. Dr. Semon believes that atrophy of the thyroid body is at the root of the whole mischief and is the *fons et origo mali*. He thought that there was no evidence to support the view that damage of the branches of the sympathetic in the neck played any considerable part in the causation.—Sir ANDREW CLARK said that it was yet open to discussion whether mere absence of the thyroid gland was the cause of the disease or whether it was the removal of the gland which set up the peculiar group of symptoms.—Dr. HALE WHITE referred to a case, recorded by Dr. Mahomed, of myxœdema which had improved under the use of nitro-glycerine. The patient, however, succumbed later on. In that case the thyroid gland was completely atrophied and none of its proper structure remained; the fibrous tissue was much increased in amount. A nuclear proliferation was detected in the liver, but all the other organs presented no special characters. The cervical sympathetic system was altered, but not more diseased than might be accounted for by the mere presence of infiltration as occurred in the rest of the body. He did not think that the disease was brought about by any direct lesion of the sympathetic system. The nerve cells were blurred and the connective tissue was swollen, did not stain well, and had a sort of sodden appearance.—Dr. W. B. HADDEN said that the presence of hæmorrhage in the history and the occurrence of cataract had been noted in other cases. Dr. Goodhart and he had observed changes in the cervical sympathetic like those described by Dr. Hale White. He could not altogether agree that the changes were purely secondary. The granular appearance of the nerve fibres was noteworthy.—The PRESIDENT said that in not one of the cases which he had seen was menorrhagia absent.—Dr. ANDERSON, in reply, said that after bleeding from the gums many years ago the patient said that her neck became swollen and the speech thick, though these symptoms disappeared a week later. Nevertheless, the same

Digitized by Google

symptoms set in again nine years later, when the myxœdema definitely began. She had received no benefit from nitroglycerine, and, although jaborandi improved the subjective symptoms, there was no change for the better in the physical state. The modified connective tissue of the retina might be involved like the connective tissue elsewhere, and the slight changes observed might be accounted for by the smallness in amount of the connective tissue.

Dr. C. H. GOLDING BIRD read notes of a case of Congenital Dislocation of the Patella in a girl, aged eleven, who for six months had been troubled with displacement of the patella on to, and afterwards quite outside, the external femoral condyle. On bending the knee or straightening it the patella resumed its normal position with an audible click. There was some pain, but the affection was more disagreeable than painful. She walked well, but with stiffened knee. The displacement was first observed after a fall. The author believed the cause of the displacement to be due to structural shortening of the quadriceps extensor following paralysis of the muscle—probably infantile—and had tried as a rational mode of treatment tenotomy of the ligamentum patellæ; but the only gain was the disappearance of the click, the dislocation occurring as before. He thought the name paralytic dislocation preferable to congenital. His case agreed with the description given by Hueter. The case had been exhibited at the Society early in the year.—Mr. RICKMAN GODLEE referred to a similar case in a girl, aged six years, which he had shown at the Society. The view that the shortening of the extensor muscles was the cause of the dislocation was not concurred in. Mr. Godlee said that his patient complained of no discomfort, although the affected limb was much shortened and wasted.

Dr. CARRINGTON showed a drawing of a case of Skin Eruption due to the administration of Bromide of Potassium. There was no history or appearance of syphilis in either of the parents. An elder child three months old had suffered from impetigo capitis. The patient was born quite healthy, and with trivial exceptions remained so up to about ten months. At that time he began to suffer from convulsions and symptoms which seemed to point to meningitis, and he was treated with an ounce and a half mixture containing one scruple of bromide of potassium, of which one drachm was given every four hours; this was for a time administered every three hours, and the ammonium was for a time substituted for the potassium salt. This treatment was persisted in for about seven weeks. The eruption appeared in the form of minute red papules, which in the course of three or four days attained the size of a penny-piece. The parts affected were the buttocks, legs, thigh, and, to a smaller extent, the scalp and face. When first seen the spots were of variable size, from a pin's head to a penny-piece. The smaller ones were of a bright-crimson colour, and smooth, the largest ones of a dark-brownish hue, circular or elliptical in form, with a sharply defined edge of at least one eighth of an inch in thickness. They were of a spongy texture, without the least trace of fluid contents. The treatment adopted by the practitioner under whose care the child came was half a grain of potassium iodide and one minim of liquor arsenicalis three times a day. In a fortnight there was very great improvement. Some of the spots had disappeared, and were represented only by pinkish discolouration, and the others were much shrunken and nearly level with the skin. No new ones had appeared. The child made an uninterrupted recovery; and when seen two months after all the lesions had disappeared with the exception of two or three on the scalp and face, which took the form of dried up scabs. The eruption was never moist from beginning to end. It was worthy of note that an eruption due to the bromide should disappear under the administration of the iodide of potassium.—Dr. DYCE DUCKWORTH said that the case was somewhat peculiar in that the sebaceous glands were said not to be specially involved. The bromide eruption was a confluent [illegible] whereas the iodide eruption was a dermatitis in which the sebaceous glands were not specially affected.—Dr. STEPHEN MACKENZIE spoke of a case of bromide eruption in which he had made a microscopical examination of a large number of sections (*vide* THE LANCET, vol. i., 1884, p. 997). The inflammatory changes which existed were shown to be most marked in the vicinity of the hairs and embryonic sebaceous glands. In Dr. Chelmsley's case and in the new Sydenham Society's Atlas the tubercular pustular eruption was well depicted. The eruption always occurred in children. As regards the diagnosis, it was important to know that the eruption might come out some time after the administration of the drug was begun, and to remember that the disease lasts a much longer time after the disuse of the medicine; the disease may be thus prolonged two or three weeks. The appearance of a large flat-topped corrugated eruption was amply sufficient for diagnosis.—Dr. BARLOW corroborated the statements of the previous speaker as to the prolongation of the disease after the removal of the bromide. It was necessary to insist on this point, for some eminent dermatologists had said that the rash stopped when the offending cause was removed. It was extremely likely that there was an idiosyncrasy with respect to the elimination of iodide and bromide salts from the system. In Dr. Lees' case Dr. Stevenson found bromine in the urine three weeks after the cessation of the administration of the medicine. These salts were, as a rule, rapidly eliminated. Moreover, the skin eruption may be set up by so small a dose as a grain and a half of bromide of ammonium.—Mr. MORRANT BAKER said that the excretion of iodide was generally retarded by advanced disease of the kidneys, as he had witnessed in a remarkable case of iodide eruption.—Dr. DYCE DUCKWORTH corroborated this testimony.—Dr. STEPHEN MACKENZIE thought there might be a tendency to too wide a generalisation. He watched for two or three years a case of Bright's disease in which drugs caused no peculiar manifestation.

Mr. GODLEE read a paper on a case of Nephrectomy in an Infant. The child, a boy aged one year and ten months, was admitted under his care at the North-Eastern Hospital for Children in August, 1883. The tumour was first noticed in June, 1883, and was growing rapidly. It was on the right side, and measured four inches in the long diameter and about two in the short. It was freely movable, and manipulation caused no pain. There were no urinary symptoms. The kidney was removed by the lateral abdominal (Langenbuch's) incision, and the removal was readily accomplished, as there were no adhesions to surrounding structures. The cæcum and the duodenum were the only pieces of bowel exposed. One large vein which ran over the tumour alone required ligature. There was no hæmorrhage of consequence, and the whole operation was concluded in half an hour. The child had no symptoms of any kind after the operation. It ate and slept as well the next day as before, and the temperature rose to 99° only once, the day after the operation. It left the hospital well six days later. It continued well till February, 1884, when recurrence took place in the right iliac fossa, and the tumour rapidly increased in size, passing down into the scrotum, and the child died soon after. Mr. Godlee mentioned eight other cases which have been recorded, showing that of them five had died of the immediate result of the operation, two had recovered well but died afterwards of a recurrence, and one was well when last heard of. Notwithstanding the unsatisfactory nature of the results he argued that, seeing how hopeless the condition is if this alone, we should endeavour to remove these tumours in a still earlier stage, at all events until it is proved that even this proceeding is invariably followed by a fatal result. He particularly, however, pleaded against attempting the removal of the very large growths which are not unfrequently met with, showing that they will almost certainly have involved surrounding structures, and that then while no good can follow the operation an immediately fatal result is probable. The tumour weighed about one pound, and was in structure a mixed sarcoma, most of the cells being roundish or oval, but some spindle-shaped. This is probably the usual composition of these growths, but another class was mentioned in which striped muscular fibres exist. The latter are probably congenital, and often affect both kidneys, and are thus not favourable for surgical interference.—Mr. BARWELL doubted whether the operation for removal of sarcoma of the kidney would ever be justified by the results. Incision on the outer side of the rectus abdominis was probably far better than the lumbar incision, as Langenbuch had said; for there was much less chance of bleeding.—Mr. MEREDITH related the case of a little girl, aged four years, in which a renal sarcoma of rapid growth had taken place. On examination a "bossy" irregularly shaped tumour was situate in the right side of the abdomen, having all the characters of a renal tumour. After consultation with Sir Spencer Wells extirpation was decided upon. During the operation the capsule gave way; the pedicle was then found and tied in two halves; the ureter was secured. There was but little hæmorrhage. Collapse soon [illegible] death followed on the third day.—Mr. [illegible]

found that both the lungs were studded throughout with new growths, which had yielded no sign of existence during life; the extreme rapidity with which apparently secondary infection might occur was remarked upon. The vena cava was found to be completely occluded by the ligature, but, probably owing to the collateral circulation having been opened up before the operation, this occlusion had given rise to no signs. The ureter was found to be distended with urine to the size of the little finger, and the theory of regurgitation might account for this distension. He thought it would be better to bring the divided end of the ureter out into the abdominal wound in future operations. The tumour turned out to be a round-celled sarcoma; the urine was perfectly normal throughout the course of the case.—Mr. KNOWSLEY THORNTON thought that such cases as Mr. Godlee's ought not to be operated upon, because the fatal results added to the statistical mortality of the operation known as abdominal section. He was firmly convinced that if we could eliminate such unsuitable operations abdominal section might become the most successful operation for nephrectomy. He had performed this operation ten times with uniformly good results.—Mr. A. E. BARKER could not concur with the remarks of Mr. Barwell that the anterior layer of the mesocolon would most likely present itself in the operation for nephrectomy by abdominal section. He referred to a case in which he had used the median incision, and then he came down on the growth with the greatest ease; the external layer of the mesocolon was almost necessarily incised in Langenbuch's operation, but the anterior might possibly present if the median incision were adopted.—Mr. RICKMAN GODLEE, in reply, said that it was not easy to determine the position of the colon; where the tumour was large the bowel was emptied of air, and so palpation only was of service. He thought that Mr. Meredith's case should not have been operated on. In his own case a little clot projected into the vena cava. Mr. Thornton considered that he took a too sanguine view of these cases, but such was not the case. In three cases which he had recently observed it did not seem advisable to interfere surgically. The abdominal section had the advantage in that secondary deposits in the viscera could be felt for during the operation. In his case he allowed the ureter to take care of itself, and this without evil consequences; it was the outer side of the colon that he passed through in getting at the tumour.

Dr. KINGSTON FOWLER exhibited a living specimen of Pigmentation of the Tongue in a man, aged forty, suffering from phthisis.

MEDICAL SOCIETY OF LONDON.

AN ordinary meeting of this Society was held on Monday last, Mr. Arthur E. Durham, F.R.C.S., President, in the chair.

Mr. SPENCER WATSON read a paper on a case of Chronic Hypertrophic Rhinitis. The case was unusual in many respects. A nurse girl, aged twenty-one, had been suffering from nasal discharge, occasionally offensive, for a period of eighteen months before she was first seen. There was obstruction of both nostrils, with all the symptoms of chronic inflammatory disease of the nasal passages. The obstruction was due to excessive hypertrophy of the turbinate bones and their overlying mucous membranes. Several portions of the hypertrophied bone and mucous membrane were removed by operation, and the channels dilated by ivory plugs. At the same time sprays of various kinds were used, and a course of arsenic given internally. The result was very satisfactory; the senses of smell and taste were restored, and the free respiration through the nostrils re-established. The instruments employed and the portions of tissue removed were exhibited, and the patient was present for inspection. The nostrils were seen to be nearly normal in appearance and the passage quite free for respiration.—The PRESIDENT spoke of the importance of the subject, and of the frequent association of chronic hypertrophic rhinitis with mucous polypi, together with the liability of confusing between them.—Dr. GIDEON GARDINER referred to the presence of a discharge having an offensive odour passing down the œsophagus into the stomach. He had employed glycerine of carbolic acid and a powder of starch and iodoform in equal parts as an insufflation.—Mr. WALSHAM thought it was difficult to decide whether the catarrh was caused by the stenosis or *vice versâ*. But he was sure that the hypertrophy kept up the catarrh when the stenosis reached a certain degree. He had removed a part of the inferior turbinate bone with considerable benefit, though the relief was not always permanent. In displacement of the septum nasi which sometimes accompanied the disease the rectification of the septum had done much good. Nitrate of silver on a probe could be employed with much benefit; he had also used chromic acid and iodoform.—Mr. WATSON, in reply, was convinced of the value of chromic acid, which he thought was the best caustic.

Dr. BRAXTON HICKS exhibited an apparatus for Dry-air Disinfection, which is described in another column.—Dr. ROBERT BARNES thought the employment of this apparatus was of immense importance in the lying-in chamber, and for deodorising linen and clothes. He considered that no articles should come back from the laundry without being subjected to the influence of a dry-air disinfector.

Dr. KINGSTON FOWLER read a paper on False or Functional Cardiac Murmurs, which will be published in a future number of THE LANCET.—Dr. SAMUEL WEST noticed that a very large number of the murmurs were exocardial; some of these murmurs were due to movements of the air in the lung, but these were probably rarer than those due to conditions of the blood. Mental excitement might cause a murmur in the second right intercostal space, and the presence of such a murmur might lead to the "refusal of a life" at an insurance office. He spoke of the blowing systolic murmur at the left apex in cases of chlorosis. Reference was also made to functional murmurs in the course of rheumatic fever. Dilatation of the axillary artery might accompany the signs of dilatation of the left ventricle. The intraventricular origin of murmurs was defended.—Dr. SANSOM said he estimated Dr. Fowler's paper as a most practical one. It was most important not to give offhand answers in regard to the nature of any murmur. He agreed with the views of Ludwig and Hesse, which referred regurgitation to temporary feebleness of the muscles which close the auriculo-ventricular orifices. He could not believe that the murmur heard at the second left intercostal space was due to mitral regurgitation, as held by Balfour and Naunyn. The excessive vibration of the septal segment of the mitral valve was the probable cause of the murmur heard at the left base in cases of anæmia.—Dr. ANGEL MONEY referred to the frequency with which the sounds over the right ventricle and pulmonary artery were altered and rendered louder in conditions of obstruction of the pulmonary circulation.—Dr. KINGSTON FOWLER briefly replied.

OBSTETRICAL SOCIETY OF LONDON.

A MEETING of the above Society was held on Wednesday, October 8th, Henry Gervis, M.D., President, in the chair.

The following were the specimens shown:—1. Two Cysts of the Broad Ligament filled with Tarry Fluid, removed by Abdominal Section, by Dr. Malins. 2. The Ovaries and Tubes, removed from a case of Pyosalpinx by Operation, by Dr. Malins. 3. Tumour of the Upper Part of the Vulva, removed by écraseur, by Dr. Potter. 4. Pelvis from a case of Mollities Ossium, by Mr. Griffith. 5. Cyst of the Uterus, by Mr. Griffith. 6. Ovarian Tumour, by Dr. W. Duncan. 7. Neugebauer's Intra-uterine Glass Tube, by Dr. Barnes. 8. Glass Female Catheter, by Dr. Barnes.

Mr. J. HOPKINS WALTERS read a paper on Post-partum Avulsion of the Uterus, with a case followed by recovery. In April, 1882, Mr. Walters was called by Mr. Cockran of Caversham to a patient aged twenty-two, in her third confinement. She had been attended by a midwife, who, after the birth of the child, finding the placenta did not come away, pulled at the cord, which broke at its attachment. She then introduced her hand and tore away the whole of the uterus with the right ovary and Fallopian tube, portions of the round ligaments, left Fallopian tube, and ligament of the left ovary attached to it. Mr. Walters saw the patient twenty-one hours after the accident, and found her under the influence of opium, and somewhat recovered from severe collapse. A large quantity of omentum protruded from the vulva, and in the upper part of the vagina was an enormous rent. Mr. Walters ligatured and cut away the omentum, which was cold and badly bruised, at the level of the vulva; the parts were washed with solution of permanganate of potash, and a pad of salicylated wool applied. The opiate was continued; cathe-

Digitized by Google

terisation ordered every eight hours, and the diet limited to milk and beef-tea. The patient did well until the fifth day, when she was seized with shivering; her temperature fell to 97·4°, and the pulse rose to 170. Mr. Walters irrigated the vagina with solution of permanganate of potash, and, finding that the vaginal fundus had well closed round the omental stump, afterwards used a solution of carbolic acid; quinine, in large and frequent doses, was combined with the opiates, and the vagina syringed every eight hours. On the twenty-eighth day the patient was able to drive five miles to the Royal Berkshire Hospital, where she remained under Mr. Walters's care until the beginning of July, when the omental stump had frittered away, and the vaginal wound was perfectly cicatrised. At the present time, two years and a half after the mutilation, the patient is in perfect health and attending as usual to her ordinary occupations. After a diligent search Mr. Walters has found reports of thirty-six cases of accidental removal of the puerperal uterus, of which fourteen recovered. Of all these, only three were, without doubt, unattended by previous inversion of the uterus. Having regard to the medico-legal aspect of these cases, Mr. Walters draws an important distinction between the accidental removal of the previously inverted uterus and of the uterus that has not undergone inversion, on account of the possibility of uterine separation through spontaneous rupture. According to present experience, inversion of the uterus is not found to coexist with rupture either of that organ or of the vagina; and where it is shown that the uterus was inverted before being torn away, it becomes tolerably easy to estimate the degree of criminal responsibility attaching to the attendant. On the other hand, where it can be proved that the uterus was never inverted, it is impossible to assert that the separation of the uterus was wholly due to violence, and not contributed to by a spontaneous rupture through the uterine or vaginal walls. Mr. Walters quotes cases and authorities to prove the occasional insidious occurrence of uterine rupture, the suspension of symptoms, and the completion of childbirth in spite of it, in some cases independently of manual interference, and without any disproportion between the maternal passages and the child; and concludes that in giving evidence in such cases, these facts should be most carefully remembered.

Dr. P. HORROCKS read a paper on a case of Rupture of the Uterus. M. B——, aged thirty-four years, was in her ninth pregnancy; in the eighth one, twins were born fifteen months ago. In her ninth pregnancy labour came on at full term, and nothing abnormal was noticed when she was first examined; the os was dilated and the membranes bulged through it; presentation vertex. Two or three severe pains came on, following one another very quickly, and the vertex appeared at the vulva covered by the unruptured membranes. These were immediately ruptured and the child (alive) was driven entirely outside the vulva by the powerful parturient action, which had at the same time caused a rupture of the uterus running nearly longitudinally but inclining obliquely downwards to the left, and involving part of the body, the whole of the cervix, and a portion of the upper part of the vagina. There was not any external hæmorrhage, and the patient seemed all right for about ten minutes, when she became faint and collapsed, vomiting some dark brownish fluid. The placenta was expelled by the uterus after injecting hot water into the vagina. The author arrived soon after this, and found the rent already described. The patient died from shock before anything could be done. There were only a few clots in the pelvis.

The PRESIDENT remarked on the value of Mr. Walters's paper, both from the forensic and obstetric point of view. He did not quite gather in what way the projecting omentum had disappeared, and he would like to ask whether examination had detected undue softening of the uterine tissues.—Dr. AVELING asked if any penal action had been taken against the midwife. He thought the case another strong proof of the necessity of passing a Bill to ameliorate the present ignorant and dangerous class of midwives.—Dr. BRAXTON HICKS thought that in Mr. Walters's case there was already a rent of the junction of the uterus and vagina, and that the midwife had passed her hand through the rent in mistake for the flabby os uteri, had pulled down the omentum in mistake for the placenta (an error he had seen before), and then the uterus. Rupture of the uterus and vagina is produced by the essential contractions of the uterus, and bearing down pains are not necessary. When an obstacle occurs to the head of the fœtus after its escape from the os, the uterine force is expended on the uterus and upper part of the vagina as a kind of recoil. When a laceration has once begun, but little force is needed to extend it, and when the fœtus is placed nearly symmetrically, the vagina may be torn all round. The broad ligaments are not capable of resisting much force, nor are the round ligaments. A very slight force will free the uterus after the severance of the vagina. In the case of Popplewell's, alluded to in the paper, he was assured privately that no force had been used. He did not think that in simple removal of the placenta from a sound uterus and vagina it would be possible to tear the uterus away. After the uterus has been torn away from the vagina and most of its attachment, bearing down might conceivably complete its detachment and expulsion. — Dr. CHAMPNEYS said that the uninverted uterus might conceivably be torn away by inserting one or more fingers through the cervix, retroverting the fundus, hooking the fingers backwards and pulling.—Dr. BARNES confirmed the view taken by Dr. Hicks that the uterus had the power by virtue of its *vis insita* of contracting and pulling on the vagina and broad ligaments even apart from any central nervous supply, for a short time at least. Expression of the placenta (practised by the midwife in Mr. Walters's case) requires caution, and may produce inversion. The proper way is to use both hands, and press the anterior wall against the posterior.—Dr. HERMAN said that in any future case of the kind in which evidence on the subject might be required in a law-court, all available facts would be found in Mr. Walters' paper, which had shown that in certain conditions avulsion of the uterus is effected with great ease, and had been frequently effected by qualified medical men. Remembering the rarity of these cases, and the sudden emergency which arises, a medical man should not be hastily condemned as a criminal, and still less a midwife.—The PRESIDENT said that while avoiding hasty condemnation in any individual case, in the absence of a knowledge of all the facts, he could not but regard the avulsion of a whole uterus, inverted or not, as a very grave and responsible proceeding.—Dr. GRIFFITH referred to a case in which a fibroid had been mistaken for the placenta. Post-partum hæmorrhage had induced the practitioner to use some force, which might have inverted the uterus.—Dr. BRUNTON thought the removal of an inverted uterus a sign of incompetence, or even criminality, seeing that the absence of inversion can be easily proved by abdominal palpation of the puerperal uterus.—Dr. BARNES replied that the uterus might be by natural efforts or aided by slight and not culpable manipulations, entirely detached. Casper mentions a case in which the broad ligaments even were torn through by spontaneous force. When the uterus was lying loose the hand introduced to remove the placenta might easily bring it away, and the practitioner be blameless. Those of largest experience would judge most mercifully.—Mr. WALTERS, in reply, said that the omentum, after becoming highly vascular, slowly disintegrated by molecular death and disappeared. He did not receive the uterus until many days had elapsed, and consequently no microscopical examination of its fibres was made. It looked, however, perfectly healthy and of quite average thickness throughout its walls. No penal action was taken against the midwife, and he was thankful this was so, as, although he still believed great violence was used, he should have given much stronger and more positive evidence against the woman than subsequent study of the histories of these cases would have justified. Comment had been made on the various ways in which, during operative procedures, the uterus might be detached from its connexions, but one mode had not been mentioned—viz., that in the attempted introduction of the hand within the uterus, either for turning or to remove retained secundines, the organ might be forced up and the tissues of the cervix or vagina, if friable, torn through. He would feel greatly obliged if Fellows would bring to his notice any account of similar cases not included in his paper.

MEDICAL OFFICERS OF HEALTH SOCIETY.

Metropolitan Sanitary Administration.

THE first meeting of the session was held on Oct. 17th, when the President, Dr. ORME DUDFIELD, delivered an inaugural address. After congratulating the Society on the complete success of the conference at the International Health Exhibition, managed by the Society conjointly with

Digitized by Google

the Sanitary Institute and Parkes Museum, and referring to the services of Dr. Northcote Vinen, who had resigned the post of hon. secretary after more than twenty years' service, he proceeded to deal with the subject of Metropolitan Sanitary Administration. First of all he sketched his idea of what a London Government Bill should be, in an abstract of the address deliver by him in the previous session, and then compared the sketch with the scheme of the Home Secretary. There was so much of similarity in the two that he could not consistently enlist himself in the ranks of the opponents of the Bill. After referring to the grounds of opposition raised by the Corporation and local boards, and taking into consideration the probability of the Bill not meeting with acceptance in Parliament, he proceeded, in the second place, to suggest an alternative scheme. The Corporation might be left alone, or, under a reformed constitution, allowed to rule over the City; the Metropolitan Board of Works being placed, in regard to the rest of London, in the position assigned in the Bill to the new Common Council. The vestries would be maintained in their present position as local executive bodies, subject to efficient control by the Board, so as to secure the desired unity and uniformity. Reference was made to the mode of election of members of the Board and vestrymen, and to plans by which this might be amended. Whatever scheme might be adopted—that of the Government or such a one as he suggested—the Central Board, as the chief sanitary authority, should be endowed with the powers and duties with respect to infectious diseases, provision of hospitals and ambulances, &c., at present exercised and performed by the Asylums Board. It was possible, of course, that no Bill might get adopted. The Bill of the Government might be rejected and they might refuse to bring in another. He proceeded to ask therefore, in the third place, whether it was inevitable, in either contingency, that London should wait indefinitely for an instalment of reform in its sanitary administration? Reciting the powers already existing which, *inter alia*, enabled the Metropolitan Board to make bye-laws in regard to a variety of matters, he contended that if such powers were exercised, covering as they did pretty well the whole field of sanitary administration, London government might be conducted in a fairly satisfactory manner by the existing authorities. He stated his reasons for believing that the framers of the Metropolis Management Act must have contemplated a close union between the board and the vestries, such as he advocated, and cited several sections of the Act which enable the Board to make bye-laws for regulating the drainage of houses, disposing of refuse, &c., and to make orders for the guidance, direction, and control of the vestries in regard to sewerage. Theoretically, nothing more, nothing better, could be desired, provided only that the vestries carried out their part in the matter by loyally enforcing the bye-laws. But no such bye-laws for regulating drainage and disposing of refuse were in existence; while, with regard to sewerage, no definite principles had been laid down, each local board having its own views on the proper size and material of sewers, the differing plans being equally approved by the Board. Having in view the probability that no opportunity of dealing with Metropolitan government would be forthcoming next session, a time of grace was afforded which, if wisely used in efforts to put existing powers into force, might avert the necessity for any material change. But if the vestries, for instance, desired to prolong their rule, they must prove their utility; and more than one opportunity of doing this was offered. For example, they must deal with the dwellings of the poor, in regard to the state of which the public conscience had been greatly stirred; as witness the formation of the Mansion House Council and the appointment of a Royal Commission. The power to make regulations for houses let in lodgings or occupied by members of more than one family must be exercised. The Society had framed standard regulations for their guidance in 1879. Few of them had exercised the powers, but if they had sinned by their neglect it was in good company, as the Local Government Board had failed until within the last few months to exercise its power, conferred in 1874, of declaring the enactment of Section 35, Sanitary Act, 1866, to be in force in all parts of the metropolis. The Society had framed useful regulations for the guidance of sanitary authorities in supervising bakehouses. Illustrations of the value of bye-laws were cited, special reference being made to those framed by the Metropolitan Board with regard to foundations and sites of buildings, under the Building Act, 1878; to offensive trades, under the Slaughter-houses (Metropolis) Act, 1874; and to dairies, cowsheds, and milkshops, under the Dairies, &c., Order of 1879. Incidentally the Slaughter-houses Act had led to a great reduction in the number of private slaughter-houses, while the offensive businesses regulated had been conducted subject to definite regulations, enforced by an irreducible penalty for any breach, in a satisfactory manner, quite impossible when they were subject to the general law of nuisance only. The Society had taken a leading part in promoting sanitary reform in connexion with offensive trades, dairies, and cowsheds. The legal status of the local authorities and of their medical officers in relation to the regulated businesses was unsatisfactory. They should have statutory powers to carry out the bye-laws under the general supervision of the Metropolitan Board. Regulations made by the vestries providing for the periodical removal of manure were rendered nugatory by the reluctance of magistrates to inflict adequate penalties for breaches. Some limits should be set to the power of magistrates to reduce and remit penalties for offences against sanitary laws. Good work might be done under the water regulations if the sanitary authority had concurrent power with the water companies to enforce them. The Local Government Board had urged the vestries to bring about "severance of all connexions of waste-pipes of cisterns with drains," but this, as it had been pointed out to the Board, could be done universally by the companies only—viz., by the exercise of their power under Regulation 14. The companies had responded in some measure to the representations of the Board by issuing a notice to their customers, calling attention to the advice with regard to waste-pipes, cleansing of cisterns, &c., given by Sir Francis Bolton, the water examiner, in his monthly and annual reports. The power of water companies to cut off water for non-payment of rates should be totally abolished. When all existing powers had been exhausted Parliament would confer whatever additional powers were proved necessary. Among others the Metropolitan Board should have that of fixing upon sites for mortuaries and disinfecting chambers, and for baths and washhouses upon a plan so arranged as to provide for the needs of the population irrespective of local boundaries. Having so far dealt with "sanitary powers," the address next dealt with "sanitary difficulties," which were partly inherent in the law itself, and partly incident to the method of its administration after this had passed from the sanitary to the judicial authority. There was no power to punish the person who created a nuisance, however grave or long-continued it might be, and it took an inordinate time to get a nuisance abated, when the author of it proved recalcitrant. The public, naturally supposing sanitary law to be the embodiment of common sense as applied to matters of public health, were too apt to regard the sanitary authorities as all-powerful but apathetic, and to lavish blame upon them for not abating nuisances immediately upon discovery or report. But the law was too considerate of the rights of property, and too leisurely in its movements to allow of this being done. Months even might elapse before a nuisance could be abated. Aggrieved tenants were liable, moreover, to be made to pay compensation to the landlord, in the shape of increased rent, for the trouble and expense to which he had been put. The remedy for the state of things described was twofold. The magistrates should have power (as outside London they have, under Section 96 of the Public Health Act, 1875) to inflict, by their order, a substantial penalty on the author of the nuisance, and the vestry should have power to enter upon the premises to abate the nuisance when it was certified by the medical officer to be dangerous to health, and the time allowed in the vestry's notice for its abatement had expired. Reference was made, in conclusion, to cases that had come before the courts, in which tenants had proceeded against their landlords to recover damages for injury to health, resulting from drainage and other structural defects. Decisions had been given in their favour and were of importance as precedents. There should be an implied warranty when a house was let that it was fit for human habitation.

On the motion of Dr. Bristowe the thanks of the Society were given to the President for his address; and on the motion of Mr. Shirley Murphy, seconded by Mr. F. M. Corner, it was resolved to print the address and forward it to the Local Government Board, the Metropolitan Board of Works, the vestries and district Board, and other parties interested in the question of London government.

The proceedings of the meeting were brought to a close by

Digitized by Google

the presentation of a testimonial to the retiring hon. secretary, Dr. Vinen, in the shape of a handsomely engrossed and framed copy of a resolution passed at the annual meeting held at the International Health Exhibition in June.

LEEDS AND WEST-RIDING MEDICO-CHIRURGICAL SOCIETY.

THE first meeting of the Society for this session was held on Oct. 10th, the President, Dr. Bell, in the chair.

The PRESIDENT delivered an introductory address, in which he contrasted the practitioners of fifty years ago with those of modern times as regards education, general and professional, social status, work, and physique. The latter he maintained to be better in the older practitioners, who had to face all weathers without the luxurious carriages in present use, while the rare use of old midwifery instruments caused the hours of work to be longer. The practitioners of to-day shrank from many duties which formed part of the routine of past times and midwifery tended more and more to fall into the hands of women.

Dr. MYRTLE read a paper entitled "Sweating to Death." The patient, a healthy active man, after suffering for three weeks from pains of a rheumatic character relieved by sodium salicylate, was seized with profuse sweats, which were frequently of a most offensive character, lasting at times for ten hours. Atropine and ergotine both caused sudden symptoms of collapse. He improved for a time on arsenic, and the perspiration lost its fetidness. He died from exhaustion 121 days after he first felt the flying pains. No post-mortem could be obtained. Dr. Myrtle regarded the case as one of paresis of nerves supplying the sweat-ducts, caused by frequent exposure to cold during his employment.

Dr. BRAITHWAITE, Dr. HUTCHINSON, and Mr. WHEELHOUSE related cases of Excessive Sweating, which in one instance was relieved by the external application of belladonna liniment, and in another by taking copper sulphite.—Dr. JACOB thought the intermittency of the attacks precluded a peripheral paresis, and pointed rather to the sweat centres being affected.

Dr. SOLOMON SMITH read a paper on Visceral Neurosis, urging the view that these were often reflex, and not due to nervous defect. One might conceive that through the nervous system a continuity was maintained between all the cells of the organism, and that the activity of any organ was not due to a stimulating force originating in any so-called "centre," but to stimuli resulting from the sum total of the impressions received by the nervous system from every part of the frame. A neurosis, then, might either arise in consequence of morbid centripetal impulses from other organs, or from primary defect of the nervous system. More good could therefore be done in many cases by relieving peripheral irritation than by nerve medication.—Dr. CLIFFORD ALLBUTT also urged the importance of investigating peripheral causes in nervous gastric disorder. He denied that a non-neurotic subject could be rendered neurotic by overwork or exhaustion.

Mr. MCGILL read a paper on two cases of Charbon. In the first the patient was inoculated while skinning a beast known to be diseased. He was admitted to the infirmary with cellulitis of the arm, and died collapsed in a very rapid manner. The second case presented a well-marked pustule on the arm, which was excised, and the patient recovered. In the first case no bacilli were found in the blood during life, but many immediately after death.

Dr. JACOB showed the Malignant Pustule from the above case mounted in glycerine jelly. He also showed microscopic specimens of Bacilli Anthracis from the two cases above, and from two recent cases of woolsorters' disease which had occurred in Bradford, together with diagrams showing this structure of the pustule and the forms of the bacilli.—In the discussion which followed Dr. BELL gave an account of similar cases, pointing out the want of correspondence between the constitutional and local signs in many of these cases. It was also mentioned that some fifteen of the beasts known to be diseased had been recently sent to the Leeds market; and we must therefore presume, as no ill-effects had followed, that the spores of the organisms could be destroyed by the heat used for cooking.—Drs. BRITTON, RABAGLIATI, and S. SMITH joined in the discussion.

Mr. A. W. MAYO ROBSON showed a patient on whom he had operated in March, 1884, for Ununited Fracture of the Spine of the Scapula, which had been produced by a fall of earth fifteen months previously. He had been treated at first by his own doctor, and afterwards as an out-patient at the Leeds Infirmary, but when he was admitted for operation a gap of an inch could be felt between the fragments, and the arm was useless. The refreshed ends were united by two silver sutures, which were pressed down flat and left in. The operation was done antiseptically. The result was most satisfactory, the patient having a useful and powerful arm, with all its movements perfect.

Reviews and Notices of Books.

Diseases of the Heart and Thoracic Aorta. By BYROM BRAMWELL, M.D., F.R.C.P.E. Edinburgh: Young J. Pentland. 1884.

IN this elegant and profusely illustrated volume Dr. Bramwell has entered a field which has hitherto been so worthily occupied by British authors—Hope, Hayden, Walshe, and others; and we cannot but admire the industry and care which he has bestowed upon the work. As it stands, it may fairly be taken as representing the standpoint at which we have arrived in cardiac physiology and pathology. For the book opens with an extended account of physiological facts, and especially the advances made of late years in the neuro-muscular mechanism of the heart and bloodvessels. Although in this respect physiological research has outstripped clinical and pathological observation, Dr. Bramwell has, we think, done wisely in so introducing his treatise, and has thereby greatly added to its value. Following this chapter there is one on the general pathology of cardiac lesions, which in the main consists in a systematic and orderly classification of the various functional and organic derangements. Then comes a lengthy exposition of the methods of clinical investigation, including an analysis of the various symptoms of heart disease. Amongst these latter we find an elaborate discussion of the phenomenon of Cheyne-Stokes' respiration, in which the various theories advanced by Filehne and Traube are dealt with, and a view of the mechanism of the symptoms, illustrated by a series of diagrams, stated. It must be confessed that the author is right in his assertion that we have still much to learn concerning this curious phenomenon, and we trust that many will be prevailed upon to employ the form of inquiry he publishes in the observation and record of cases that may come under their notice. The physical examination of the heart is treated at great length, and, particularly as regards cardiac murmurs, it may fairly be said to be exhaustive. It could hardly be expected that the author would fail to notice the views advanced by Balfour and others respecting the nature of functional murmurs, for he has already entered the lists against Dr. Balfour's hypothesis. At the same time it must strike the reader that perhaps too much space has been devoted to this single but highly interesting point, and the impression left after the perusal of these pages is that the question is one almost insoluble. It affords, however, an opportunity to the author of showing his skill in argument and critical analysis, with the result that he falls back upon the long-accepted doctrine that chlorotic murmurs have their origin mainly in the pulmonary artery, at least in the early stage. Remarks on the use and teachings of the sphygmograph conclude this chapter.

The chapter on pericarditis does not call for much by way of comment. It is abundantly supplied with tables intended to contrast the points of differential diagnosis between the conditions of pericardial effusion, cardiac hypertrophy or dilatation, hydropericardium, exocardial and endocardial bruits, &c. The signs of adherent pericardium are discussed, their enumeration being given as follows:—1. Systolic depression, instead of systolic protrusion, of the

Digitized by Google

apex beat; and in many cases a systolic depression of the lower end of the sternum and adjacent costal cartilages. 2. Permanent depression of the præcordial region. 3. A diastolic rebound of the chest wall. 4. Absence of the apex beat. 5. Fixation of the apex beat. 6. When the lungs are at the same time retracted and fixed by adhesions, the area of pericardial dulness is not only enlarged, but remains of the same size during inspiration and expiration. 7. Distension of the veins of the neck during the systolic depression of the chest wall—i.e., during the systole of the ventricles—followed by their rapid collapse and disappearance during the diastolic rebound—i.e., during the diastole of the heart. Under Endocarditis, the author discusses, first the "simple," and then the "ulcerative" form, giving a very clear account of the latter, which so often complicates chronic valvular disease, but the etiology of which is still so obscure. We note that Dr. Bramwell is strongly persuaded that acute endocarditis is sometimes transient, adducing in support of this view the fact that the preponderance of fatal cases of chorea present valvular vegetations, the inference being that such have also been present in non-fatal chorea with fugitive murmurs. He is also inclined to believe that the early murmurs in rheumatic fever are organic and not anæmic, even though they may disappear; but he suggests that some of these bruits may be due to myocarditis without any valve inflammation. As to treatment, he is a staunch upholder of the free administration of salicin as early as possible in a case of acute rheumatism; and thinks that it is possible to anticipate and prevent endocardial inflammation by such treatment. He agrees with Dr. Maclagan in discarding salicylate of soda from its alleged depressant action on the heart, but we must confess that the evidence of this is not very convincing. The subject of valvular disease is next dealt with fully, and forms indeed one of the most attractive sections of the volume. The sixth chapter is devoted to diseases of the myocardium, and the seventh to neuroses—viz., palpitation and angina pectoris. A chapter upon thoracic aneurysm terminates a work which from the scientific manner in which the subject is treated, from the care and discrimination exhibited, and the copious elaborate illustrations with which it is adorned, is one which will advance the author's reputation as a most industrious and painstaking clinical observer.

OUR LIBRARY TABLE.

Madère étudiée comme Station d'Hiver et d'Eté. Par le Docteur JULIUS GOLDSCHMIDT. Pp. 36. Paris: Delahaye et Legrosnier. 1884.—This work gives a short account of Madeira and its climate, illustrated by thermometric, hygrometric, and barometric tables. The author, after a brief notice of the prevailing diseases to which residents may be exposed, has given in detail the cases which, in his opinion, are likely to derive benefit from a residence there. His advice and cautions to invalids are judicious. Full information is afforded as to the various routes by which the island may be reached and the accommodation provided for visitors. The book is evidently intended chiefly for the use of French invalids; and the author states, as one of the drawbacks of the island, that, while in the hotels and boarding-houses there is every comfort to be found, there is also English cookery. It seems well adapted to afford information to the class for whom it appears to have been written.

Aix-les-Bains (in Savoy). The Medical Treatment and General Indications. By Dr. BRACHET. Pp. 174. London: Renshaw. 1884.—This work has been written with the purpose of showing the value and influence of the medical treatment of Aix-les-Bains and Marlioz. An analysis of the waters by M. Wilm is given, and a detailed account of the mode of using them, but there is no information afforded respecting the climate. The greater part of the book is taken up with an account of the diseases to the treatment of which Dr. Brachet considers the waters to be applicable, illustrated with notes of cases. The author, in our opinion, has fallen into the very common error of including far too many diseases in this category. As far as we can gather the diseases in which the waters of Aix should be avoided are very few, and may be grouped as "congestive phthisis, complicated by intense febrile symptoms and repeated hæmoptysis," cancerous diseases, atrophy or hypertrophy of the heart, dilatation, or aneurysm of the heart and of the large vessels, angina pectoris, and nervous irritability or congestion of the brain. An analysis is given also of the sulphurous waters of Marlioz and Challes. The last forty pages of the book are devoted to an account of Aix-les-Bains, its accommodation and amusements, and of the places of interest which may be visited from it.

The Journal of Physiology. By MICHAEL FOSTER. Vol. V., No. 3 and Supplement to Vol. V.—The present parts contain the following memoirs and a bibliography of the physiological papers published in 1883:—1. Schäfer: A Method of Recording Changes of Volume by Means of Photography and its application to the Plethysmographic Record of the Normal Frog Heart, with a Plate. 2. By the same author: A Description of the Piston Recorder, an apparatus for Recording and Measuring the Changes of Volume of the Contracting Frog Heart, with a Plate. 3. H. Sewell: On the Physiological Effects of Light which enters the Eye through the Sclerotic Coat. 4. H. C. Wood: Note upon Antipyretic Salines. 5. S. Politzer: On the Temperature Sense; a Contribution to the Physiology of the Skin as an Organ of Sense, with a Plate. 5. W. D. Halliburton: The Proteids of Serum, with a Plate.

The Quarterly Journal of Microscopical Science. Edited by Professors LANKESTER, DYER, KLEIN, MOSELEY, and ADAM SEDGWICK. No. XCVI. October, 1884.—This part contains a memoir by William Patten of Boston, U.S.A., on the Development of Phryganids, with a preliminary note on the Development of Blatta Germanica. Mr. Patten found in the earliest stages of the yelks examined by him numerous germ-cells, together with an irregular network of protoplasm. All the nuclei and the protoplasmic network migrate to the surface and become converted into blastoderm, which becoming thickened at one point forms the ventral plate. From this plate cells arise by budding and migrate into the yelk and ultimately form true entoderm cells. All the mesoderm arises from an invagination which takes place along the median line of the ventral plate. The further stages of the development of these insects are carefully followed. 2. A memoir on the Development of Halisarca lobularis, a species of sponge, by W. J. Sollas. 3. A contribution to the knowledge of Rhabdopleura, by Ray Lankester. 4. A description of Caldwell's Automatic Microtome. 5. H. Caldwell, on the arrangement of the Embryonic Membranes in Marsupial Animals. 6. Alice Johnson, on the fate of the Blastopore and the presence of a primitive Streak in the Newt (Triton cristatus). Justus Carrière, on the Eyes of some Invertebrata. Lastly, a note on Protoplasmic Movement. This part closes Vol. XXIV. It contains 23 plates.

The Medical Chronicle. A Monthly Record of the Progress of the Medical Sciences. Vol. I. No. 1. Manchester: J. E. Cornish. This new periodical has started well, and we wish it every success. The original contributions, five in number, are of excellent character. Dr. Roberts of Manchester writes on Tests for Albumen; new and old. It is needless to say that this contribution is a masterpiece of clinical chemistry. Dr. George Johnson, however, takes exception to certain statements concerning the picric acid test. The article by Dr. Dreschfeld on the Pathology of the Lung Complications in Diabetes is a careful study of the

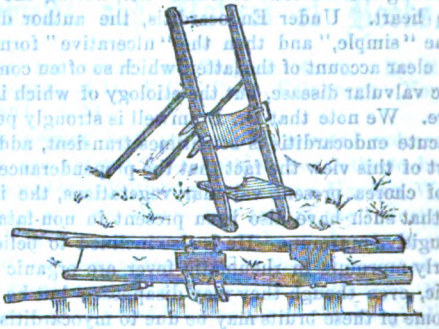
Digitized by Google

subject, and is sure to be widely read. Of the department headed "Chronicle" we shall say but little, but we must remark that the abstracts are well done, and will serve the purposes to which they will be put. Medicine, Therapeutics, Surgery, Midwifery, Diseases of Women, Diseases of Children, Physiology, Diseases of the Eye, of the Skin, of the Ear, of the Throat, Forensic Medicine, and Toxicology are the subtitles of the Chronicle. We have said sufficient to show that *The Medical Chronicle* is a careful and thorough attempt to place before its readers a record of the progress of medicine.

The Social Code, 1884. Compiled by GEORGE AGER, LL.D. pp. 224. London: Effingham Wilson. 1884.—This code, enabling the senders of telegrams to express themselves in few words, is specially adapted for the everyday requirements of social life. The advantages of secrecy and economy are attained, and by limiting the number of words the chances of error in the transmission of messages are reduced to a minimum. Those who are in the habit of extensively using the telegraph, especially in connexion with foreign countries, will find this code extremely serviceable.

New Inventions.

APPARATUS FOR DRY-AIR DISINFECTION.



DR. BRAXTON HICKS showed at the Medical Society of London, on October 27th, an economical apparatus for antiseptic treatment by medicated air, simple and cheaper than others, but on the same principle. It was made for him by Mr. James Allen (21, Marylebone-lane), and is worked by foot bellows manufactured by Griffiths (Garrick-street). It consists of a pewter cylindrical vessel, having a screw lid, this having itself a smaller opening with a screw lid (A in figure). There are two openings (C and D) with tubes, one

opposite the other; that in connexion with the bellows (C) dips down to the bottom inside. The interior of the vessel is filled with sponge clippings, saturated with carbolic acid, eucalyptol, thymol, pine oil, or any other volatile substance, single or in combination. The large lid enables one to fill or remove the sponge; through the smaller lid the sponge can be charged or moved about. Rubber tubing connects the one side with the bellows, and the other with a tube to direct the air-current. To warm this current, and to increase the percentage of volatile material, the apparatus can be placed in hot water. The size of the apparatus exhibited was ten inches high and four inches in diameter. It was pointed out that it afforded a ready means of disinfection and of deodorising the air of a chamber.

A NEW BED-LIFT.

THE accompanying engraving represents a new bed-lift and chair combined, shown by Mr. Newham at the rooms of the Medical Society of London on the 20th ult. The seat is placed under the knees of the patient. The levers, one on each side, are hooked to the seat, which is then

drawn close to the body of the patient; the band is then passed under his back, and buckled to the opposite side. The patient can now, by raising the levers, be lifted without any effort on his part into a sitting position. The manufacturers are Messrs. Viney and Co., 181, Great Portland-street, W.

SINGULAR CAUSE OF DEATH.

To the Editor of THE LANCET.

SIR,—I beg to call your attention to the facts sworn to at an inquest, held by me at the Surrey County Lunatic Asylum, on October 3rd, 1884, on the body of J. S——, aged thirty-one years, an inmate.

The deceased was admitted into the institution about a week before her death, suffering from delusions, amongst others, that she had imps in her stomach, who were constantly coming into her mouth, and that smoke was coming out from the walls in order to smother her. The evidence of the medical officers was to the effect that they had never noticed that she evinced any suicidal tendencies, but that she was extremely careful of herself and dreaded any harm coming to her. She was at times refractory and excitable, and on the night of September 29th, being in that state, she was sent to bed in a room by herself at an early hour; no one but the attendants having access to her room. At 10.20 P.M. she was visited by an attendant, and was then seen to be quietly sleeping in her bed. On being visited about two hours and a half afterwards, she was found lying dead on her face, with a large quantity of her night dress crammed into her mouth. The attendant endeavoured to pull it out, but so firmly was it fixed in that the medical officer was sent for, and after some difficulty he removed it, and immediately marked in pencil the part that was wet, in order to ascertain how much she had swallowed. It was then found that about *one half a square yard of thick coarse calico* had been thrust down her mouth and throat.

The jury came to the conclusion that the deceased had thrust the calico down her throat in order to stifle the imps in her stomach, and without any thought that in doing so she would deprive herself of life, in which conclusion both the medical officers concurred, and they therefore returned a verdict of death from misadventure.

The case seems interesting from the fact that so much of the calico could have been forced by the deceased down her mouth and throat before all muscular power was lost.

There are cases somewhat similar mentioned in the works of medical jurisprudence; but none that seem to approach the facts of this case in regard to the quantity of material swallowed by the deceased or in the evident absence of suicidal intention.

I remain Sir, yours faithfully,

A. BRAXTON HICKS,
Elm-court, Temple, E.C., Oct. 1884. Deputy Coroner for Surrey.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 1, 1884.

A CRISIS in the history of medical education in this country seems to be rapidly approaching, and unless action of a vigorous and thorough kind be taken, a few years may witness a remarkable and indeed a deplorable state of things. There is no need to disguise the fact—it is patent to all who have taken any part in medical teaching—that the large share which the metropolis has hitherto enjoyed in this work is being seriously threatened. It hardly seems credible that this great city, the home of upwards of 4000 medical practitioners, a number exceeding one-fourth of the total number in England and Wales, with its abundant material for medical study, its numerous schools, and vast army of hard-working, earnest, and able teachers, a place which has no equal in the world as regards the resources for such education, should be in danger of losing the favour it has so long enjoyed. Yet from all sides—from the teachers who see their most promising pupils pass from their view before their course is completed; from the students themselves, who find out that the advantages of study in London are more than counterbalanced by the exceptional difficulties in the way of their attaining adequate acknowledgment of their labour; from the practitioners, who deplore the fact that a university degree was denied to them because they had been brought up in London and not in Edinburgh—the same cry comes. Nor does the general impression lack the support of statistics. One of our contemporaries published last week some figures contrasting the entries of medical students in the London and in the Scottish schools for the past few years, which show a steady decline in the former and an increase in the latter. Again, it is a notorious fact that a large proportion of the graduates of the Scottish Universities are Englishmen, which is clearly shown from figures supplied from another source; that amongst all the medical practitioners of England, 61·2 per cent. hold Scottish degrees, and only 20·3 per cent. are graduates of one or other of the English Universities. Couple with this the fact that 98 per cent. of the medical practitioners in Scotland hold a degree from a Scottish University, and the reason for the declining popularity of the London schools is manifest. There is a growing desire to be possessed of a qualification which shall carry with it the title of "Doctor," and the student or his advisers perceive that no more learning is needed, no greater effort demanded, to obtain such a diploma in other places than is required in London to obtain a mere licence to practise. Nor is it by any means unusual for students to abandon their London career at a time when they would be most able to profit by its continuance, in order to complete their education and to fulfil the necessary conditions of residence at the University. They may have to go over the same ground, but they find that the attainment of a degree is not more difficult than would have been the labour for the diploma or licence of an English College.

To all this it may be replied that London does possess a University, and that London students can pass through its portals if they choose. Those who argue thus little know the irony contained within such counsel. The University of London demands a curriculum of more than ordinary extent, and it does undoubtedly place its standard very high. The rejections of candidates for medical degrees are numerous, especially at the Preliminary Scientific M.B. and the Intermediate M.B. examinations; but this would not of itself deter candidates provided that the regulations of the University were made more elastic, and these primary examinations held with greater frequency. Were it otherwise a far larger number of those who, by competing for the Scientific Examination, show their desire to obtain the degree would eventually attain their object. On the present system the loss of time which one rejection entails, added to the "glorious uncertainty" of passing, diminishes the roll, and eventually out of every 100 medical undergraduates but ten complete their full course. It is conceivable that a remedy may be found by the University itself undertaking the gigantic task of reorganisation of metropolitan medical education, and becoming something more than a mere degree-granting body. It might do this successfully without changing its scheme of education, which, after all, does not notably differ from that of other universities, and, by placing itself more *en rapport* with the teaching centres, so remodel its examination system that every London medical student should pass through its hands. It is idle, however, to speculate upon possibilities which will never be realised. That the University of London will ever depart so far from the spirit of its foundation is not to be dreamt of. Its Senate conceives that the mission of the University is of a different kind; and well-meant suggestions for facilitating the graduate's career without diminishing the severity of the tests to which he is subjected have either been misunderstood or deliberately disregarded.

A fundamental obstacle to the University assuming such functions as would place it on a similar footing to that of other universities is that it would practically disestablish the ancient Colleges which for generations before the University was founded did the work of licensing the English practitioner. This work they are still pursuing, and, by a device which unhappily contains within it a blemish likely to defeat its object, they have just mutually agreed to combine for the purposes of examination. This scheme will require modification, notably in the matter of fees, or else it will only quicken the tendency of medical students to forsake the London Schools. But, as we all know, the cause of such an exodus is not solely one of outlay; that is one factor, but the essential thing is, as we have already pointed out, that for the same expenditure of time, thought, and money the student can elsewhere obtain the much-coveted titles of M.B. and C.M., which bear an intrinsic value higher than any membership or licentiateship of any college, however respected and illustrious. Why, then, should not the union of the Colleges be made still closer, and the wedge driven further home? With all the influence they possess, is it difficult to believe that they could fail to establish a University of Physicians and Surgeons, which should not merely examine, but actually control, the resources of medical education in the metropolis? We live in an age of progress and of centralisation. And with regard to our ancient Royal Colleges, the time is coming when their

Digitized by Google

independent existence will be threatened, unless they submit to the force of events, and merge their individuality in an institution which will enable them to retain the control they have so long held over medical education. It is futile to dream of establishing another brand-new university when the materials lie ready at hand for the evolution of an institution which would knit together the centres of medical learning scattered throughout the metropolis, and comprise them all under one compact and well-ordered organisation. Nothing short of this will avert the fate that seems to be impending over the London medical schools.

THE views held with regard to the perineum and its functions vary much; not less so do those regarding the evils resulting from simple laceration of this structure. Some authorities hold it to be one of the main supports of the pelvic viscera. This view of the perineum is by no means uncommon, but no one has enunciated it in so definite and distinct a manner as Dr. GAILLARD THOMAS. He maintains that this body sustains and prevents prolapse of the anterior wall of the rectum and of the anterior wall of the vagina; he, moreover, states that "upon the posterior vaginal wall rests the anterior, upon this the bladder, and against the bladder the uterus, all of which depend in great degree for support upon the perineal body." Further, the perineal body, according to Dr. THOMAS, "preserves a proper line of projection of the contents of the bladder and rectum, and this prevents tenesmus, a frequent cause of pelvic displacements." These functions are performed by what Dr. THOMAS calls the keystone action of the perineum. This account of the perineum is the most boldly original conception of this body and its functions ever given to the profession. A keystone composed of soft and yielding tissues is not only a novel but an unintelligible idea; but Dr. THOMAS is not satisfied with this, for he observes that the keystone is inverted, its apex is directed upwards, and it is attached to the very structures it supports. This extraordinary conception deserves to be kept in remembrance, for if it be true, Nature, in the formation of the female perineum, has accomplished not the improbable, but the impossible.

Others, again, maintain that to support the uterus and to keep it in the pelvis is not one of the functions of the perineum. The pelvic organs are maintained in position by other structures and other means. Dr. MATTHEWS DUNCAN has taught this for many years; and Dr. EMMETT, in a paper read before the American Gynæcological Association, has recently maintained the same view. Dr. EMMETT says: "My belief is that a simple laceration of the perineum, even to the fibres of the sphincter ani, produces no inconvenience after the parts have healed, and only occasionally do we find disturbance of a reflex character due to the presence of cicatricial tissue." This statement appears to be based upon another, the accuracy of which the experience of everyone who has seen much of the diseases of women will confirm. "We can all recall," states Dr. EMMETT, "instances illustrating the condition where the perineum, even in the case of labouring women, had been lacerated for years, with no discomfort, notwithstanding that the vaginal outlet had remained so open that it was a matter of surprise to find the pelvic organs in place." He holds that "the pelvic fascia, forming a sulcus along the side of the vagina, is reflected over the muscles in an attachment around the junction of the vagina with the external soft parts, so that with the subpubic ligament above, the connexion with the coccyx behind, and the tuber ischii on each side, a firm support is given to the outlet."

The old operation of BAKER BROWN, with its various modifications, however small it may have left the vaginal outlet, fails ultimately to check the evils which have been generally attributed to laceration of the perineum. If for a time it prevents the uterus from appearing outside the vulva, this respite is but brief; the tissues united soon yield to the superincumbent weight, and the womb becomes again procident, while in many cases it is maintained in the pelvis from the first by the aid of a pessary only. This operation is effectual only when a portion of the posterior wall of the vagina has been included in the new union.

Upon the view of the pelvic fascia above given Dr. EMMETT has based a new operation for laceration of the perineum. This consists in uniting the posterior wall of the vagina to the posterior part of the vaginal outlet. The denuded parts consist of two transverse crescents, one at the vaginal orifice, and the other on the posterior wall a little above the orifice. To discover the surfaces to be united, the patient should be placed in the lithotomy position, and the lower portions of the caruncule on either side are to be seized with tenacula, together with the corresponding surface on the posterior wall of the vagina, and the three points are to be brought together. The apparently deep tear of the perineum appears then as a comparatively superficial sulcus. After denudation the transverse crescents should be united first, and then the perineal sulcus. Dr. EMMETT has found this operation to restore the parts to their primitive state before laceration, the repair thus far being permanent.

THE "cycling" community, to judge from its defence to the vigorous attacks recently delivered against it, has been aroused to a sense of the responsibility incurred by advocating the general adoption of a method of travelling at once economical and graceful.

It is not our purpose to enter minutely into the *pros* and *cons* of the arguments adopted by contending sides, but rather to strike a balance on broader grounds between conflicting opinions. Violent exercise—or strain—is undesirable, whatever form it may assume, but in no other case is it of such moment as when it threatens the integrity of structure and the regularity of function of organs necessary to the maintenance of life. It can scarcely be doubted that many a youth has had a career of brilliant promise cut short by the acquired incompetency of his aortic valves, consequent on indiscretion in rowing. In cycling the tension on the circulatory system is decidedly less, but still sufficient to constitute an element of danger, especially when an effort is made to set an example or "beat a record." With regard to the injurious effects of cycling upon the genito-urinary organs, much may be said on both sides. It seems reasonable to suppose that long-continued pressure or frequent impact of the perineum against the pommel or horn of the saddle might end in local thickening, and even stricture of the urethra, to say nothing of ulterior evils; but our investigations

Digitized by Google

lead us to conclude that, to say the least, such results are exceedingly rare. We very much doubt if it can be shown that irritation of the genito-urinary apparatus by similar means conduces to the acquirement of evil habits in youth, inclining as we do to the belief that there is no greater safeguard against such practices than physical exercise, which strengthens the body and invigorates the mind. But, be this as it may, there should be no difficulty in entirely removing the disputed cause. If the saddle is made of sufficient width to receive the weight of the body fully through the ischial tuberosities, it would be next to impossible for the urethra to be compressed, or the perineal muscles to be thrown into a state of spasm. Excessive use of the lower limbs, incidental to cycling, has a decided tendency to cause prolonged overfilling of the superficial veins, and to the development of permanent dilatation and varicosity. We know of one case in which, from this very defect, a member of our own profession barely satisfied the requirements of the "physical examination" prior to admission to the naval service.

Considering the strain thrown upon the thighs and adjacent parts of the abdomen, it would not be surprising if now and again cases were recorded in which hernia had been acquired by "wheelers" possessing original weakness of the structures bounding the inguinal canal and its apertures, but such a mishap seems to be of very rare occurrence. With a machine made in accordance with the principles inculcated by experience as to what is safest and best to protect from injury, we doubt if any valid argument can be raised against its moderate use. The state of irritability of the spinal cord, known in America as "railway spine," on account of its supposed dependence on repeated concussions from the jolting experienced in long journeys by rail, can scarcely be a frequent consequence of cycling. The natural provisions for the protection of the cord, coupled with the resiliency of a bicycle or tricycle spring as now employed, are competent safeguards against any serious lesion of the nerve centre, either functional or organic, provided the employment of the machine is not pushed beyond reasonable limits.

A VERY important resolution affecting the sanitary administration of the metropolis was arrived at on the occasion of the last meeting of the Metropolitan Asylums Board. For many years past the failure of the metropolitan vestries and district boards to provide adequate means for the isolation of the infectious sick of their respective districts has been matter of great public concern, and the legal proceedings which have for some time past followed on almost every attempt to erect a new infectious hospital, whether permanent or temporary, have evidently put it almost altogether out of the power of such bodies to meet the increasing demand for proper means of isolation. This was fully recognised by the Legislature when, in 1883, owing to the prevalence of cholera in Egypt, the Diseases Prevention (Metropolis) Act was passed; for under this statute it was definitely enacted that the admission of a person suffering from any infectious disease into a hospital belonging to the Asylums Board should not be considered as parochial or charitable relief. In the first instance the Act was only put in force for one year; it was, however, renewed during the past session, and in view of what are apparently the intentions of the Government as regards the future, the Metropolitan Asylums Board have had the whole subject under consideration. The report of the special committee dealing with the matter has been before the managers, who have expressed concurrence with it, and the result is that they have come to the conclusion that the time has arrived when patients suffering from infectious disorders should be admitted to the managers' hospitals upon the orders of medical officers of health, as well as upon those of district medical officers and relieving officers, whose orders alone have hitherto been received. Nearly all the sanitary bodies of London have expressed their concurrence in the views taken by the managers, and since it is now quite evident that this is the only way out of a great and pressing difficulty, it is to be hoped that the application which is about to be made to the Local Government Board to give effect to it will meet with the approval which the importance of the subject demands.

On one point alone we hesitate to agree with the opinions which were expressed at the meeting. Several of the managers wished a representation to be made to the sanitary authorities urging them to obtain repayment of the expenses of isolation from the friends of the patients who might be sent into the hospitals, and pressed that instructions might be given to the officers of the authorities to secure such payment. We cannot but think that experience has proved that this recommendation was not a wise one. Patients are removed to infectious hospitals not so much in their own interests as in the interests of the public, and it is the community that should pay for the safety which they thus secure, much in the same way as vaccination and systems of house scavenging are paid for out of the public funds, either of the country or the district concerned. Besides which, infectious hospitals are constructed and maintained at the cost of the public rates, and this element should certainly be taken into consideration when it becomes a question of admitting into such a hospital any person from a ratepayer's household. Sanitary authorities are not so much given to recovering the cost of isolation as they formerly were, and we think it very unlikely that individual inhabitants of London will often be called upon to pay for removal to an institution which is maintained for the protection of the public generally.

Annotations.

"Ne quid nimis."

EXAMINATION FOR PROMOTION IN THE ARMY MEDICAL SERVICE.

WE have received a revised copy of the regulations in regard to the examination of surgeons and surgeons-major of the army. The most important alteration in them is the abolition of the examination of surgeons-major in operative surgery and practical medicine, to the objections to which we last week called attention. This will now be required only of those officers who have not previously been examined for promotion to the rank of surgeon-major. The revised circular also removes a doubt which had been expressed as to the exemption from this portion of the examination, accorded to Fellows of any Royal College of Physicians or Surgeons of Great Britain or Ireland, being applicable to

Digitized by Google

surgeons-major, and it omits the qualifying clause that the fellowship must have been obtained five years subsequent to the officer's entry into the service. An exemption from all further examination is also granted to medical officers of any grade promoted for distinguished professional service. We hope that this may be taken as an intimation that promotion on this ground is not to be in future, as it has hitherto been, a nullity. We are glad to find that the Director-General has so promptly taken steps to remove what were, in our opinion, valid objections to the new regulations, and trust they will now be found to act beneficially for the soldier and the profession, without inflicting any injustice or being supposed to cast a slight upon the medical officers.

LAYING DOWN A "RULE OF LIFE."

THE *St. James's Gazette* observes, "It really seems sometimes as if hygienic science were all wrong, and as if late hours, much hard work done under the gaslight, and the smallest possible amount of fresh air were the way to be healthy, if not wealthy and wise. Who lives under more (theoretically) unhealthy conditions than the members of Parliament or the leading counsel learned in the law? But our statesmen are in a green old age at seventy-five, and barristers are quite boyish at sixty; so, too, are actors and actresses." Our contemporary then exclaims, "Sanitary guides should tell us the meaning of these things." So far as we may presume to respond to this appeal, we must be allowed to point out first that there is a fallacy in the inference that because Members of Parliament, busy counsel, and perhaps actors and actresses, live on in spite of the adverse influences of surroundings which are held to be injurious to health, therefore the surroundings of their lives cannot be as injurious as they are supposed to be. One of the earliest exploits in the applied science of statistics as brought to bear upon sanitary questions was the drawing of an inference that because the London night-men, who slept as they might by day, and spent the hours of darkness in emptying cesspools, were able, as a class, to claim a very low rate of mortality, their mode of life and the work in which they were engaged could not be unhealthy. A good deal of excitement, we remember, was produced by this delivery some forty years ago. It was forgotten that another point of view was possible, and that, in truth, none but the inured could live at all under such conditions! That since excogitated law, the "survival of the fittest," explains the result. So it is with members of parliament, busy counsel, and actors and actresses. The weakly and sensitive retire or die, or have the wit not to enter into a way of life which must obviously prove unsuitable. At the same time, we are quite prepared to meet our contemporary half way in his argument, though the inference with which he opens the debate is obviously faulty. We *do* think that a great deal of unpractical nonsense is talked and written on the conditions of health, and we are quite sensible of the fact that regimen and dieting may be pushed too far. It is true that "what is one man's meat is another man's poison." Practitioners and those who set themselves up as apostles of sanitary science are too prone to measure other people's corn by their own bushel. For example, a physician or surgeon may himself have been a too free liver—it is easier to preach than to practise,—and he may have become a total abstainer just in the nick of time, or with great advantage to his health; but this is certainly no reason why he should spend the remainder of his life in trying to persuade others that total abstinence is good or necessary for *them* also. Again, a medical man may have a miserably weak digestive faculty, and need to avoid certain dishes which other folk can take, not only with impunity, but with benefit; but that is no reason why he should go about abusing and interdicting the things that disagree with him, while they agree perfectly well with the majority of mankind. By pushing dieting to the verge of starvation, we are simply pretending to cure, not curing; we impose on ourselves and those who confide in our practice. In principle, the same is true of artificial modes of life. The matter is one which deserves professional attention.

THE LONDON SCHOOL BOARD AND "OVER-PRESSURE."

As a matter of course, School Boards will not take kindly to the discovery and exposure of the fact that a deadly wrong has been doing and is still done under their patronage. As well ask a criminal to form an impartial judgment of his own crime and to award a suitable sentence, as look to a School Board for a satisfactory vindication of the rights of common sense in education. There is a perfectly natural ring about the objection urged the other day at a meeting of the London School Board: "To appoint a special committee simply to satisfy one medical man was a thing that he (Sir Edmund Currie) could not conceive as coming within the province of the Board. If they agreed to the inquiry at all, he hoped it would be entrusted to persons who understood something about the matter—the School Management Committee." This is admirable; precisely what must have been expected. Meanwhile, may we not ask whether it is not just possible that some day—we know not when or how—a grain of intelligence may be discovered secreted in a stray official mind, and that the outrageous stupidity of talking like this may then become apparent? If some mal-practice were detected in the culinary department of Sir Edmund Currie's domestic establishment, would he refer the duty of "inquiring" to a committee of his kitchen maids, because they "understood something about the matter"? Why, that is the very reason of all others why the question should not be so referred. Not one medical person—though Dr. Crichton Browne is accepted as spokesman—but the whole profession demands inquiry and reform, and "the School Management Committee," which has so long failed to recognise the evil, is certainly not the body to which the duty of scrutiny or revision should be entrusted.

SUCCESSFUL EVACUATION OF THE FEMUR.

DR. TASSI presented a patient to the Academy of Medicine of Rome on May 25th last, on whom he had successfully operated for persistent osteomyelitis of the femur. The operative procedure was so formidable, and the result so satisfactory, that we translate Dr. Tassi's communication to his colleagues, with only a few immaterial omissions. The patient, a youth aged fourteen, from Aquila, of good constitution and parentage, first suffered two years previously from commencing osteitis of the internal femoral condyle. In the course of a few months the pathological process invaded the whole epiphysis, and an abscess formed at the lower opening of the Hunterian canal. On the patient's admission into the Ospedale S. Giacomo, on Jan. 8th, 1884, with acutely urgent symptoms of purulent osteomyelitis, free exit was given to a subperiosteal abscess, and two large drainage-tubes were introduced. The inflammatory symptoms having subsided, the patient was placed under chloroform on Feb. 4th, and the soft structures freely divided between the vastus internus and the ring in the adductors. A large chasm was then made in the internal condyle, and with the operator's spoon the interior of both condyles and of the whole epiphysis was evacuated as far as the peri-articular shell. It then became easy to evacuate the marrow and to scrape out the bone affected with osteomyelitis, purulent in some parts, fungous in others. The breach in the bone exceeded five inches in length. The cavity was washed out

Digitized by Google

immediately after the operation, and then filled with very fine iodoform. A plaster-of-Paris apparatus was then applied to the whole limb, leg and thigh included, and only removed once in the course of three months. When the lad was presented to the Academy the bone was wholly reproduced, there was no ankylosis, and he was in excellent health. Dr. Tassi added that he had at that time three similar cases in process of recovery in his wards in the Ospedale S. Giacomo.

SIR MOSES MONTEFIORE.

WELL done, Sir Moses Montefiore! It may now be hoped that we have heard the last of the opinion that in modern times no human life has been proved to reach 100 years. With the extending term of human life and the steady improvement in human habits, life has often seemed to reach 100 years and more. But this has not frequently been the case in persons whose history was so well known as that of Sir Moses Montefiore. He was born at Leghorn on Oct. 24th, 1784, whither his parents had gone on a business journey. His birth was duly entered in the books of the Spanish and Portuguese synagogues in Bevis Marks. It is a grand thing to live to 100 years and to be still cheerful and thankful. It is so, in the first place, for the pleasure of rebuking such sceptics as Sir George Cornewall Lewis, and in the second for the pleasure of giving all men proof that there is nothing in physiology to make it impossible for them to achieve a century of honourable and agreeable existence. We do not wish to magnify mere longevity, or to make every man believe that by any amount of thought he can necessarily attain to it. Our study of longevity leads us to think that it is generally a constitutional, and often a hereditary, matter. It is more important to live well than to live long.

> "Nor love thy life, nor hate; but what thou livest
> Live well; how long or short permit to Heaven."

It is in this spirit, and doubtless largely because of this spirit, that Sir Moses has attained to his 101st year. It should not be forgotten that in the last decade of it he accomplished no less a feat than a journey—the third he had made—to Palestine. And it is only by so "living well" that anyone is likely to attain to an enjoyable and unselfish old age. Living well in the vulgar sense of the word is one of the surest ways of failing of this achievement. There are a few men whose powers of vitality and whose integrity of tissue are so exceptional as to enable them to almost disregard the laws of health; and their survival to a high age often leads careless observers to wrong conclusions; but there is nothing more certain than that for Jew or Christian—and Sir Moses shows how much there may be in common between a good Jew and a good Christian—the great secret of longevity is to "live soberly, righteously, and godly."

SANITARY ARRANGEMENTS AT CAMBRIDGE.

WE publish elsewhere a letter from an undergraduate of Cambridge describing the accommodation afforded at a class of lodgings by no means unfrequently licensed for use by the junior members of the University. Within the last few years the numbers that annually enter at the University have increased out of all proportion to the residential capabilities of the colleges, in spite of the new buildings that many of them have recently erected. The demand for lodging-house accommodation has therefore considerably increased, and many small tenements that a few years ago would have been considered altogether unfitted for the purpose are now eagerly sought in order to lodge the surplus undergraduates. To this there would be no objection if these buildings were kept under strict sanitary supervision, which we regret to say is not the case. Our Commissioners, who have visited the town, can bear out the statement made in the present letter with regard to the position of many of the waterclosets in relation to the kitchens, living rooms, and bedrooms. Many of these closets are utterly without provision for ventilation, and often with a very inadequate water-supply. And the danger from this source is aggravated at Cambridge by the fact that the town drainage is in an unsatisfactory condition, and that dangerous pressure of sewer gas, and sometimes actual outburst of sewage, occur at weak points in the system. Of course, so long as the inspection of these lodging-houses is entrusted to a clergyman, we cannot expect it to be efficient from a sanitary point of view. It is quite right that a clergyman should be appointed to inquire into the moral atmosphere of undergraduates' lodgings, but there ought to be associated with him an efficient sanitary inspector to attend to more practical matters. No licence should be granted to any house for the reception of students unless it can be shown that it is protected from the town sewers by an efficient trap, that every closet in it is ventilated and abundantly supplied with water, and that all waste-pipes &c. are disconnected from the house-drains; whilst the licence should be countersigned at least twice every term to show that all the arrangements have been kept in working order, and that no overcrowding has been permitted. Such an arrangement as that described by our correspondent might have been possible at Cambridge during the Middle Ages; indeed it reads like one of Chaucer's tales, but is revolting in the extreme to our modern notions of propriety. We sincerely hope the University authorities will earnestly bestir themselves in this matter. It is not the first time that complaints have been forwarded to us by undergraduates of the insanitary conditions in which they are forced to live. There is no reason why the University of Cambridge should lag behind the University of Oxford in the excellent supervision of lodging-houses by a skilled sanitary inspector, aided by a staff of efficient assistants, like that in force at the latter place. The cost of such a system, which might be met by a small increase in the rent of each house, would, we are sure, be gladly paid by the parents of the undergraduates whose health and comfort would be thus largely promoted.

GAME FOR HOSPITALS AND INFIRMARIES.

SUCCESS in the treatment of disease, as every physician knows, depends greatly on efficient feeding. At times the maintenance of strength may even become the first consideration, until, it may be, some uncertain crisis has been passed and time is gained to secure the action of needful remedies. An important object in hospital dietetics, and one often difficult to attain, is variety. Without it, the most nutritious fare may fail to realise its purpose because it does not tempt the palate of the invalid or does not sufficiently stimulate his weak digestive function. Much can be done, no doubt, to obviate this defect by skill in choosing and preparing foods in common use; but nature has other resources which a little thought can render still more highly serviceable. Game supplies the want almost without contrivance. It is agreeable, unusual, delicate, and digestible. With its many forms, its native flavour, and its different possibilities of preparation, it provides a relief from the daily routine of bedside cookery which is for many as wholesome as it is certain of appreciation. We are convinced that most of those who as sportsmen are now using the gun and rifle for seasonable diversion require no further hint to remind them of the claims of the sick in hospitals and infirmaries, who have not their advantages of recreation, but whose indigent ill-health entitles them in all true charity to a share in its results.

THE COMBINATION OF THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.

THERE are 200 candidates for the first examination of the College of Physicians at this moment, while over fifty passed the third or final examination a few days ago. We do not know what proportion of these fifty took the surgical examination at the College of Physicians; but there is no doubt that students and teachers are at last recognising the fact that the licence of the Royal College of Physicians of London is a *complete* qualification in medicine, midwifery, and *surgery*. This being so, it is surely most unjust to compel the student of the future to pay thirty-five guineas for a complete London qualification when one can now be obtained for fifteen. Had the College of Physicians kept in mind the proverb "Tout vient à qui sait attendre," there would have been no inducement—not even a pecuniary one—to tempt them into the unwise scheme of combining with the College of Surgeons to hold a complete examination.

TOXIC ALKALOIDS IN THE URINE.

THE presence of toxic alkaloids in the urine, and in certain pathological liquids, has been studied by MM. Pouchet, Selmi, Bouchard, and more recently by MM. Lepine and Guérin. Alkaloids were discovered and separated from the urine in two cases of typhoid fever. When the alkaloids were injected into the lymphatic sac of frogs death followed, and the heart was observed to beat slowly before, and to be large after, death. When the alkaloids derived from the urine of pneumonic patients were injected into the lymph sac of a frog, the heart ceased to act in the systolic period, but without previous slowing of its rhythm. It appeared to be true that the urine of patients suffering severely from typhoid fever contained more alkaloid than a similar quantity of urine from a patient suffering from a slighter attack. In one of the cases of pneumonia it was discovered that the urine on the day after defervescence contained but little alkaloid, and this was not of toxic nature, whereas two days before the urine contained much poisonous alkaloid. These recent researches confirm the statement of M. Bouchard that the urinary alkaloids undergo augmentation in certain acute diseases. It was also proved that liquid extracts from the cadaver do not necessarily hold toxic alkaloids in solution.

SUSPICIOUS CASE OF DEATH FROM DROWNING.

ON the 16th ult. the Liverpool borough coroner resumed and concluded a twice adjourned inquest on the body of a girl aged thirteen, which had been taken out of the Leeds and Liverpool canal on Sept. 17th last. The following facts were disclosed at the several adjournments:—The deceased was last seen alive at 7 P.M. on Sept. 16th near a canal barge on which she had been working, and also near the spot where her body was found. It was proved that about a fortnight before her death she had made indecent overtures to a passing "flatman," though beyond this no evidence of immorality was forthcoming. As she did not return home that night, inquiry was made for her on board the flat where she had been employed, but the flatman denied her presence on board. On the next day (the 17th) her body was found floating in the canal just outside some lock gates. The body was perfectly naked, and both legs were severely injured, being smashed through the middle third of each, the wound involving the whole circumference of each, except a small posterior portion, and both bones being fractured. A post-mortem examination was made on the following day by Mr. R. W. Lowndes, surgeon to the police, who found that the cause of death was asphyxia from drowning. From the appearance of the legs, and the congested state of the internal organs, he concluded that the injuries had been caused after death. He also found the vagina so much dilated as to suggest that some violence had been done, though the immersion would tend to remove any blood stains or seminal fluid. A week after the discovery of the body some of her clothes were found in a basin fifteen yards from where the body was found. They consisted of a jacket and the skirt of a dress, but there was no under-clothing, though the mother deposed to her daughter having some on the day she was missed. The jury returned an open verdict. The clothes were carefully examined by Mr. Edward Davies, analyst of the Liverpool Royal Institution, but nothing was found tending to throw any light on the case, which remains shrouded in mystery.

CLEARING A TRACHEOTOMY TUBE.

THE sad death of Dr. Rabbeth has led to numerous suggestions of mechanical contrivances for clearing tracheotomy tubes of obstructing fluids and membranes. It is sufficiently evident to the practical surgeon and physician that most of the inventors have no idea of the calibre of a child's trachea, of the form of the tracheotomy tube that is usually inserted, or of the nature of a diphtheritic membrane. Suggestions of a pipette through which to draw the membrane, or of a kitchen bellows as a suction machine (as described in a letter from a correspondent), show a complete ignorance of the problem to be solved. A child is in danger of immediate suffocation, the membrane is thick and adhesive, and generally extends into the large bronchi, if not into the smaller divisions of those tubes. Any instrument which will obviate the necessity of sucking out the tube must be always at hand; readily applied to the tracheotomy tube, whatever differences there may be in the bore of various specimens; it must be of sufficient suction power and easily worked; and, lastly, of such a form as can be used whilst the tracheotomy tube is *in situ*. None of the suggestions recently made meet these essentials, and many are simply ridiculous. In our opinion there must be some change in the shape of the ordinary tracheotomy tube before any contrivance can be adopted which, in an emergency, would so effectually dislodge its contents, or the obstruction in the air-passages beyond it, as the ready but dangerous means resorted to by Dr. Rabbeth.

CERTIFYING INSANITY.

THE whole process of certifying insanity is so needless and mischievous in its effects and consequences, and the law controlling the practice is so defective, that complications from perverseness, blundering, or neglect are purely wanton. At Birmingham they seem to have a free and easy way in certifying the insane. Magistrates do as they please about calling to their assistance a medical man. Doubtless they feel fully competent to manage the business themselves, and being possessed with this idea, they either omit the part to be played by "the doctor" in the little drama, or they leave him to come on the scene how and when he can. A coroner has just rebuked the local justices for their irregularities in this respect, and they most richly deserve the censure passed upon them. It is intolerable that poor folk should be hurried into asylums on a mere perfunctory examination made by medical men who act together, if not technically in "collusion"; but it is much worse if a totally unskilled official, such as a magistrate, is to call to see an alleged lunatic, ask two or three common-place questions, and of his own untrained and unguided judgment certify the subject of this brief ineffectual scrutiny insane. If magistrates who are to keep the medical men in order themselves do such things, *quis custodiet ipsos custodes?*

PARLIAMENTARY REPRESENTATION OF THE UNIVERSITIES OF EDINBURGH AND ST. ANDREWS.

WE have received the report of a meeting of electors who had signed a requisition to J. H. A. Macdonald, Esq., Q.C., LL.D., Dean of Faculty, to allow himself to be nominated as a candidate to represent the Universities in Parliament. The meeting was held on the 22nd ult. The chairman, Dr. John Duncan, spoke apologetically of the fact that the Conservatives had not brought forward a medical candidate for a constituency so largely medical. His reasons were that no medical man financially sufficiently prosperous, and professionally sufficiently unsuccessful, could be found to take the post. This explanation is very unsatisfactory. For ourselves we cannot pretend to any enthusiasm in connexion with the candidature of Mr. Macdonald. One great objection to his election is that he is a lawyer, and there are already far too many men of that profession in Parliament. Their number is a misfortune for the country and for the legal profession itself. Another objection is his laudation of the medical examining system in Scotland, even that of the Corporations. He cannot have read the report of the Royal Commissioners or the evidence accompanying it, or he would not have spoken so complacently of the perfection of the work of these bodies. But what will not men say for a seat in Parliament? It is no slight satire on the choice of a lawyer for this office, who has his own views in going into Parliament, to notice that half his speech was taken up with medical questions and medical politics, on which it is evident he is just as ready to mislead the House as Sir Lyon Playfair, whom he seeks to displace. We cannot pretend, after the wreck of medical legislation brought about by Sir Lyon, to weep over any prospect of his displacement. We can only lament that the Scotch universities have no better or wiser friends than those who dare not speak of them but in terms of flattery, and who think so slightingly of their graduation system as to show a dread of public and independent tests. Time will show who are the best friends of the Scotch universities, and whether their recent action is wise.

THE SOCIAL LIFE OF THE MEDICAL STUDENT IN LONDON.

A LETTER in a daily contemporary has drawn attention to the absence of many social advantages in the life of the medical student who is compelled to live in London and other large cities. The crude idea is brought forward that, in the absence of attention being paid to the necessity of providing social comforts and proper amusements for the future doctor, Mr. Mundella and the State should step in and interfere. We think that Mr. Mundella has had such sufficient experience in legislating for the fully-fledged doctor that he is not likely to rashly interfere with the everyday life of the student. If life in a large city like London is, as we contend, the best provision, if not a necessity, for the after-practice of his profession, the medical student must perforce reside in close proximity to his daily work; and sighs after proctors, academic life, and collegiate discipline are in vain and out of place. Of what real use to discipline and morals are proctors' visits in our university cities? and the idea of such futile and antiquated methods for regulating a student's life in London is too ridiculous to be seriously argued. In some schools—King's College and St. Bartholomew's—rooms under the supervision of the authorities are provided for a certain number of medical students, and it would be well if the other medical schools also adopted this arrangement. Parents would then have room for choice in regard to a residence for their sons; but beyond this, in a city like London, it is questionable whether any other social surroundings could be secured, and even whether they would be advisable. However much it may be regretted, the hard lesson must be learnt by the parents of every medical student, that in leaving home for the metropolis social comforts must be exchanged for hard work, and self-reliance must take the place of parental or academic supervision. The study of practical medicine and surgery cannot be pursued except in great cities, and the pupil should have been prepared in early life to withstand their special temptations. The idea of a centralised block of buildings for medical students is a very old one, and has frequently been brought to our notice, but there are numerous objections, financial and otherwise, to such a scheme.

PEPTONURIA.

AMONG those observers who have closely studied the subject of peptonuria M. Grocco Pietro stands conspicuous. The conclusions at which this physician has arrived deserve considerable attention. Peptonuria is said to be a sign of disease, and to have no clinical relationship with albuminuria. It may be a symptom of general or local, infective or non-infective, disease. Malarial fevers, typhoid fever, scurvy, purpura hæmorrhagica, septicæmia, and acute phosphorus poisoning may be attended with peptonuria. Local morbid processes which produce this sign are nearly always inflammatory affections tending to the formation of pus. Some cases of rapidly increasing morbid growths are accompanied by this symptom. When a local disease is associated with peptonuria it is considered likely that the peptones are formed at the seat of mischief, and that they appear in the urine after absorption into the blood. In general diseases the genesis of peptonuria is still unknown. It is possible that peptonuria may decide between the presence of a simple and purulent inflammation. Peptonuria is frequent at the period of resolution of cases of lobar pneumonia; it may be observed during the period of grey hepatisation.

EXTRACTS OF MEAT.

A CARD and handbill concerning a certain extract of meat have been forwarded to us by a gentleman to whom they were given at the Health Exhibition by the agent connected with the business. The statements contained in both are open to objection. The card tells us that "1 lb. of the extract contains as much nourishment as 40 lb. of fresh beef." Now this is a statement likely to mislead the public, to cause much mischief, and even in some cases to lead to fatal results. As is well known, the various extracts of meat do not represent beef-tea as made from fresh beef at all; that is to say, the extract does not possess the natural fatty matters of the flesh, nor any of the proteid elements, albumen, myosin, gelatine, and the like; which latter fact is shown by their not being converted into peptones when digested with artificial gastric juice, and by their solutions not gelatinising when cold, as good home-made beef-tea should do. Extract of meat, as its name implies, consists almost entirely of the extractive matters of the flesh—matters yielded by the changes taking place in the tissue itself. The only advantage of these extracts is that, being taken in a concentrated form, these extractive matters, which are extremely soluble, pass readily into the blood, and by undergoing a further downward change, as from kreatine, uric acid, &c., into urea, and from inosite into grape sugar, furnish a certain degree of force, and so act as an immediate stimulant. But they must not be regarded in the light of food; indeed, it has been shown experimentally that dogs fed entirely on extract of meat die sooner than dogs which are kept without food altogether! This is accounted for chiefly by the excess of potash salts these extracts contain. It is therefore very wrong so to advertise these extracts to the uninstructed

Digitized by Google

public as to mislead them into thinking that they "contain as much nourishment as fresh beef." The well-known Liebig Extract of Meat Company are very clear in their statement that 1 lb. of their extract requires for its production 34 lb. of lean meat, a very different thing from saying that 1 lb. of the extract "contains as much nourishment as so many pounds of beef." Moreover, they are particular to state that their extract does not contain either fat, albumen, or gelatin. We are surprised that the authorities should have allowed such a card and handbill as that complained of to be distributed at the Health Exhibition, and thus acquire in the eyes of the public a certain degree of authorisation; whilst, in the interests of the public, we hope that in any future similar Exhibition steps will be taken to prevent traders from misleading purchasers as to the nutritive value of extract of meat.

HOSPITAL SATURDAY FUND.

UP to the present time the Board of the Hospital Saturday Fund do not see their way clear to distribute more than £9000—that is, £750 over the amount collected last year. They expect, however, £1000 more to come in. The street collection of the central districts alone amounted to £1900. The day, it will be remembered, was unfortunately wet. So this result may be considered as not unsatisfactory. But the workshop collection must still be regarded as entirely disproportionate to the means, and even the duty, of the working classes of London. And it ought to be the chief care of the Committee between now and next year's collection to develop a system of regular contributions to the Fund in every establishment. The managers of the Fund have come into collision with the Charity Organisation Society. This Society is nothing if it is not critical. It has been exercising its critical faculty on cases recommended by the collectors to the Fund. The managers resent this, and deny the right of the Society to inquire into cases recommended by them. They moreover deny the right of any Charity receiving its awards to refer cases to be investigated by the Charity Organisation Society. And they aver that their collectors, either as employers, foremen, or fellow-workmen, are more familiar with the needs and fitness of applicants than the agents of the Society can be. We have always admired the somewhat bellicose and ambitious attitude of the Fund, notwithstanding the modest dimensions of its contributions. We trust that while declining the critical services of the Society, it will not fail to use its letters with discrimination.

CASE OF THE DARENTH SMALL-POX CAMP.

THE owner of an estate in the vicinity of the Darenth small-pox camp and the Metropolitan Asylums Board have been preparing for many months for a trial which bids fair to take high rank amongst cases of a similar sort which have come before our legal tribunals. The plaintiff will contend that the camp is a source of nuisance and danger to him, and the Asylums Board will argue to the contrary. Both sides will provide abundant, and so-called skilled, evidence, and it is to be hoped that in some way or other a decision will be arrived at which will form a basis for the future action of those whose duty it is to provide for the isolation of small-pox cases. The subject is by no means a new one; but the circumstances which are now involved are exceptional. Mr. Power's now famous report went to show that whilst the aggregation of a certain number of acute small-pox cases led to a diffusion of the disease to the surrounding community, no such result followed on a much larger aggregation of convalescents. Now, Darenth camp has been essentially established for convalescents, and though at the first onset, and before the *Castalia* was ready, its use was by no means limited to such cases, yet it is the fixed intention of the Asylums Board only to send to it such cases as are either convalescent or not severe. If the cases were to be limited to convalescents the case might be less involved than it bids fair to be; but the mingling with the convalescents of cases which, though mild at the date of their removal, are in reality acute ones, introduces an entirely new element into the case. It has never yet been shown whether any distinction can be drawn, in so far as diffusion of infection is concerned, between severely acute and mildly acute cases of small-pox; neither is there any evidence procurable to show whether such huge aggregations of convalescents as are contemplated at Darenth would lead to a different result from that which was found to follow on the comparatively limited aggregation of such cases which took place at Fulham. The whole subject is a very obscure one; large interests are involved; and it is to be hoped that, when the case for injunction comes before the Court of Chancery, the medical evidence to be brought forward will be such as the importance of the case demands.

"A GREAT MEDICAL REFORMER."

IN the *Asclepiad* for October appears an article by Dr. B. W. Richardson which possesses exceptional interest for us—and we venture to hope for all readers of this journal—its subject being the founder and original Editor of THE LANCET. Under the heading "A Great Medical Reformer Thomas Wakley, M.P.: a Personal Recollection and Tribute,' Dr. Richardson gives an appreciative, kindly, and pleasantly chatty account of his acquaintance with and personal recollection of the late Mr. Wakley, and subscribes a tribute to his more public and better known acts in his capacity as a Member of Parliament, as coroner for Middlesex, and as Editor of this journal. The article is accompanied by a plate taken from a bust of Mr. Wakley.

AFTER-CARE FOR THE INSANE.

THE need of special homes for the convalescent patients discharged from public asylums, where they can be prepared for their return to the world, has been long felt. Sir William Ellis first pointed it out nearly fifty years ago; and yet nothing has been done to satisfy the admitted necessity. The After-Care Association has now been formed for the inauguration of this good work on a satisfactory basis. We heartily wish the enterprise success. It is one in which the profession must be interested, and which deserves its confidence and help. We only wish the idea could be so expanded that homes of refuge for those who, there is too much reason to fear, are on their way *into* asylums, as well as those who are on their way out, could be comprised in the scheme. The provision of such homes is, we are convinced, the one, and only, permanent solution of the problem how to arrest the development of mental disease, by establishing places of rest and treatment for those who are crossing the borderland, whether to or from the territory of mind darkness and despair.

THE SUNDERLAND MISERY.

THE distress in Sunderland is lamentable, and needs much more than the off-hand subscription of a £5 note by true friends of the poor. It is real and widespread, and must be relieved. But it will be a further misfortune if some light is not thrown on its cause. Sunderland up to a very recent period was one of the most thriving and prosperous towns in England. The disastrous inflation of the steamship-building business, which has brought such bad times to sailors and shipowners, brought high wages and plenty of work to Sunderland workmen. Yet, on the very morrow of a reverse, the well-to-do and prosperous workmen

Digitized by Google

appear before the country *in formâ pauperis*, without savings, and even without food. It is really time that this oft-repeated phenomenon should be thoroughly investigated and explained. We commend the subject to the Lord Mayor's attention. If he will deal faithfully with it, he will not only do good to the men of Sunderland, but to the country at large. These violent oscillations of the social pendulum are truly discreditable, not only to workmen, but to those who give a false impetus to industry, only eventually to leave all affected impoverished or ruined. The blame ought to be fairly distributed. Drink and improvidence will need to be fearlessly and faithfully exposed, if they are the real or chief factors in this Sunderland misery. But commercial gambling and mad haste to be rich ought not to escape. It will be well for the country when it wakes from the dreams of political excitement and learns the value of steady work, thrift, temperance, and commercial sobriety and integrity. Statesmen are not without their responsibilities for these crises of misfortune, though Mr. Gladstone is not without some justification in his remarkable answer to Mr. Gourley's question on this subject.

PERIODICITY IN ANIMAL LIFE ASSOCIATED WITH LUNAR PHASES.

THE annual report of the Board of Regents of the Smithsonian Institution for the present year gives an account of a remarkable worm known to the natives of the Fiji Islands by the name of Mbalolo, but to naturalists under the name of Salolo viridis. It is an annelid related to the Nereids, scientifically described by Dr. J. D. Macdonald in 1857. It is found in certain of the coral archipelagos of the Pacific, Samoa, Viti, and the Gilbert group. The Fijian name has reference to the coincidence of its movements with the moon; and when the worm makes its appearance it does so in such vast numbers that it is collected by the natives as a dainty article of food, and is so much prized that formal presents of it are often sent considerable distances to chiefs of other districts which are not favoured by the worm. The worms only make their appearance to spawn, and the time of their appearance is the day of the last quartering of the moon in October, unless that falls at the beginning of the month, in which case there will intervene another lunar month. According to Mr. Powell, there is a second appearance of Salolo each year, occurring a month after the first, consisting of such worms, probably, as were not sufficiently mature to spawn in October, or it may be of another species.

MILK AS A VEHICLE OF DISEASE.

IN his recently published annual report Mr. Shirley Murphy recalls the incidence of the serious prevalence of enteric fever which, in 1883, so widely affected the district of St. Pancras, and he points out how necessary it is, in the interests both of milk vendors and milk consumers, that the former should be required so to keep their books that it would be possible at a glance to tell whether infectious illness occurring in any special neighbourhood were related to milk received from one farm or another. We believe that something of this sort could, without much difficulty, be enforced under a revised Dairies, Cowsheds, and Milkshops Order, and as to the need of it we have no doubt whatever. There are large dairies that now supply London in such a way that the milk-supply to any one district is intentionally brought on one day from one farm, on the next from another; and this system of "sandwiching" the districts, whatever its real object may be, is certainly such as almost absolutely to defeat any attempt to discover the actual source of an infection the incubation period of which is apt to vary somewhat. The matter is well worth the attention of those who are responsible for the preparation of dairy orders.

"DEATH FROM INANITION."

WE have been favoured with some correspondence that has passed between the Registrar-General and Mr. W. G. Groves, of Woodford, Essex, concerning the use of indefinite terms in the filling-up of death certificates. The Registrar-General, whilst expressing regret that such words as atrophy and debility, &c., should be generally employed by medical men, does not see his way to interfere with the registration of certificates in which those words occur. With regard to the term "inanition," it would appear that Mr. Groves takes too exclusive a view of its application when he supposes that it is synonymous with "starvation," which to our mind carries a much stronger meaning. But even the latter term is often read in its physiological sense as signifying deprivation of nutritive matter, be it by illegal practices or through the medium of "natural causes." The fact of a practitioner delivering a certificate of "death from inanition" to the friends of a deceased person implies that he has no suspicion of foul play, because otherwise, as Mr. Groves contended, he would be offering an inducement and a cloak to crime. If all such certificates were referred by the district registrar or the Registrar-General to the coroner for investigation, we fear unnecessary trouble and expense would be incurred. Nevertheless, we entirely agree with our correspondent that it is the duty of medical men to express their opinions in unambiguous language in all cases where they have no doubt as to the grounds of their belief, and we trust that ere long unscientific phrases like "general marasmus" and "death from the visitation of God" will have vanished from the nomenclature of mortality.

ITALIAN NOTES.

A CREMATION SOCIETY has just been established at Perugia, under the presidency of Dr. Gaetano Tancetti.

Splenectomy was performed, on the 14th ult., in the hospital at Padua, by Dr. Alessio Giovanni. The patient, a woman aged forty, was affected with extreme anæmia and chronic hypertrophy of the spleen. According to the *Gazzetta degli Ospitali*, the operation was unattended with complications, and was well borne by the patient, who continued in a satisfactory state seventy-two hours afterwards.

With becoming irony, a triumph of quarantine and red tape is recorded by the *International Review of Medicine and Surgery*, published at Naples under the editorship of Professor Antonio Raffaele. Two waggons laden with chloride of lime and carbolic acid, in their passage from Switzerland into Italy, were stopped at Chiasso, a station of the sanitary cordon. Peremptory orders had been issued that all imports should be disinfected, and the officials could make no exceptions. It is not stated whether they carried out their instructions by mixing the two loads.

WATER FAMINES.

THE long-continued drought has seriously affected the water-supply in many parts of the kingdom. It is not long since Northampton was announced as being in great straits. In numberless places the supply is short, and where surface wells are relied on people have to travel long distances in order to secure enough water for the most pressing domestic purposes. Manchester and Bradford have been threatened with a water famine. The case of Bradford seemed until within the last few days especially urgent. As regards Manchester, the beautiful series of storage lakes in the Longdendale valley had received no fresh supplies from the hill-sides for some months past before the descent of the recent showers. The amount of "compensation water," which usually has to be given before the city can be supplied, runs away with a large portion of the limited supply that is available.

Digitized by Google

When the amount of compensation water was originally decided on, one of the principal objects to be attained was the maintenance of such a supply in the local streams as would secure to manufacturers using water as a motive power all the rights they had hitherto possessed. Although there are, doubtless, other points to be considered in this connexion, yet it is notorious that steam has in many places taken the place of water for the purposes of manufactures, and it would seem right that in so far as compensation water was only required for the purposes of machinery, some deduction in the amount demanded should follow on the use of steam.

MEDICAL REPRESENTATION IN PARLIAMENT.

A COMMITTEE of the Association of Members of the Royal College of Surgeons has resolved to request the Prime Minister to include in his new Franchise Bill a scheme for giving two Parliamentary Representatives to the registered medical practitioners of Great Britain and Ireland. We heartily wish success to this petition. But we are scarcely sanguine about it. The present humour of Parliament is for the rough addition of millions to the representation, not the addition of the representatives of classes. We cannot expect that this rough process will produce the most satisfactory results without some complementary franchises, amongst which such a proposal as that of the Association would deserve favourable consideration.

THE ISLINGTON MEDICAL SOCIETY.

ON Tuesday evening the session of the Islington Medical Society was opened auspiciously at the house of Mr. Wm. Cattlin, Highbury-place, with the reading of a paper on the Scientific Basis of Therapeutics, by Dr. Mitchell Bruce. The author was very happy in his exposition of the natural efforts of the body towards the throwing off and counteraction of disease, and in showing the action of remedies which have been indicated by a consideration of these efforts and a desire to imitate them. In the discussion which followed, Dr. Stokes expressed the gratification he experienced in seeing a modern physician devoting his mind to therapeutics, which he thought was too often neglected in favour of mere morbid anatomy. After a vote of sympathy with Mr. Cattlin, sen., and an expression of satisfaction at his improved health, the meeting separated.

INFECTIVE OSTEOMYELITIS.

La France Médicale says: "Les microbes continuent à pulluler. C'est le tour aujourd'hui du microbe spécifique de l'ostéomyelite infectieuse." M. Rodet has found that when the micrococci of the pus in cases of osteomyelitis are injected into the venous system of rabbits, and therefore free to choose their seat, they show a marked preference for the bones, and more especially for those parts which are in process of active growth, where they set up a severe suppurative or necrotic form of osteitis analogous to osteomyelitis in man.

THE DEFENCE OF THE DEFENCELESS.

ON Monday afternoon last the Lord Mayor opened a shelter for children at 7, Harpur-street, Theobald's-road, Holborn, belonging to the recently formed London Society for the Prevention of Cruelty to Children. We are by no means advocates of the indiscriminate formation of "Societies," and earnestly deprecate any undue interference between parents and their children. None the less heartily do we congratulate London on following the admirable example of Liverpool, Manchester, and Glasgow. The statement of one of the hon. secretaries—that since the formation of the Society in July last its attention had been called to 36 cases of starvation, resulting in fearful suffering and emaciation, and in eight cases resulting in death; to 51 cases of desertion; to 14 cases of infliction of wanton pain; and to 51 others the character of some of which could not be described—sufficiently demonstrates the *raison d'être* of such a Society. Such names as those of the Baroness Burdett-Coutts, the Earl of Shaftesbury, and Cardinal Manning afford ample guarantee of honest intention and strenuous endeavour on behalf of the defenceless.

CURABILITY OF SYPHILITIC ARTERITIS.

M. LEUDET has recently related the case of a man, the subject of syphilitic infection, who was noticed to have undergone a decided alteration in mental behaviour, to have lost memory, and to have suffered from frontal headache. Whilst these symptoms prevailed the superficial branch of the left temporal artery was seen to have become much thickened, so as to feel like a hard cord, and twice its normal diameter. Seven months later the corresponding vessel on the right side became affected in the same way, and coincidently the cerebral symptoms increased in intensity. The administration of antisyphilitic treatment was followed by the return of the affected arteries to their natural state, and by the recovery of the patient.

OXFORD GRADUATES' MEDICAL CLUB.

THIS club, which was so successfully launched during the summer of the present year, has announced the intention of holding its second gathering on Thursday, November 20th, when a dinner will take place at Limmer's Hotel. Each member is to be allowed to bring one guest, who must be a member of one of the Universities of Oxford or Cambridge. It is to be hoped that this movement will receive cordial support from all members of the profession who have an Oxford degree. The secretaries are Dr. Samuel West and Mr. John H. Morgan.

SMALL-POX IN DURHAM.

THE remarks of our Newcastle-on-Tyne correspondent in our annotation last week had reference to the prevalence of small-pox in the city of Durham, and not in Newcastle, as might have been supposed from the omission of the heading Durham. Our correspondent informs us at the same time that the disease continues to spread in the city of Durham and the neighbouring villages.

HYGIENE IN PARIS.

THE meeting of the Académie des Sciences, held on October 14th, was chiefly occupied with the reading of papers by MM. Gautier and Marey. The first related to a report on a further supply of pure water and on the sewerage of Paris. The second was concerned with the question of the propagation of cholera by means of drinking water.

BIRMINGHAM HOSPITAL SUNDAY.

OUR Birmingham correspondent telegraphs that the collections on Hospital Sunday in the town have this year amounted to £4262 *5s.*, a sum decidedly less than that collected last year.

TWENTY medical practitioners have died in Naples, out of 139 engaged in attending cholera patients, under the White Cross Society, during the recent epidemic.

DR. P. GRAWITZ, Chief Assistant at the Pathological Institute of Berlin, has been invited to act for Professor Grohe of Greifswald, who is seriously ill.

Digitized by Google

THE resignation by Dr. Herbert C. Major of the post of Director of the West Riding Asylum cannot fail to be a grave loss to that institution. During his many years' tenure of office, in which he was preceded by Dr. Crichton Browne, Dr. Major has persistently and successfully endeavoured to further the humane and intelligent treatment of the insane, and, by his individual efforts in varied histological research, has contributed much to the advancement of neurological science. We trust that his retirement from official cares may afford him leisure for further work in this ever widening field.

AT a special meeting of the Alnwick Local Board on the 16th ult., held to consider and discuss the medical officer's report, a member moved that the report be sent back to be condensed, and that the medical officer state what he had to state in as simple a manner as possible, refraining from filling his reports with voluminous grandmotherly advice. In place, however, of this motion being carried, another, to the effect that Dr. Davidson be granted a vote of thanks for the excellence of his report, was carried *nem. con.*

AT the fifteenth annual conference of the Poor-law authorities of the South-Eastern district of England on the 27th ult., a discussion was held on "the administration of the laws relating to public health and the management of highways by rural sanitary authorities." At the conclusion a resolution was adopted to the effect that the management of highways by rural sanitary authorities works well, and and might with advantage be extended.

THE following appointments at the University of Cambridge are announced:—Dr. Donald MacAlister, to be the University Lecturer in Medicine; Dr. Robert Nicholls Ingle, to be the University Lecturer in Midwifery; Dr. Bushell Anningson, to be the University Lecturer in Medical Jurisprudence.

THE University of Kiew (Russia) celebrated the fiftieth year of its foundation on Sept. 20th and 21st. Many foreign *savants* received honorary degrees; and MM. Charcot and Pasteur were present as representatives of France.

AT Lésignan (Aude) some families showed symptoms of poisoning, which were proved to have been caused by eating salads grown in vineyards treated with chemical products, which had been employed against the phylloxera.

ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE recommendations explain themselves. They are evidently designed by those who have drawn them up to make the Council more representative of the Fellows and Members, and more accountable to them; to increase the dignity of the office of President; to quicken the interest of the Fellows and Members in the affairs and administration of the College, and, at the same time, to augment the control of the members of the body corporate over the conduct and destiny of the College. It is to be earnestly hoped that the Fellows generally will give a hearty and liberal support to the proposals of the Association, for time and circumstance call for prompt and vigorous action.

RECOMMENDATIONS AND ALTERATIONS PROPOSED TO BE INCLUDED IN A NEW CHARTER OF THE COLLEGE.

The following recommendations have been drawn up by a subcommittee of the Association, and having received the approval of the General Committee will be submitted to a general meeting of the Association of Fellows, to be held on Saturday, Nov. 8th, at 4 P.M., at the Medical Society's rooms, Chandos-street, Cavendish-square, W.

I. *Respecting the Conditions of Eligibility of Fellows to be Members of Council.*—Recommended: (*a*) That subject to such limitations of standing as Fellow or Member as defined in Section 7 of the Charter, Vict. 15, any Fellow of the College shall be eligible to be a Member of Council. (*b*) Should any Member of Council other than the President be absent from more than two successive quarterly meetings, or from more than four successive ordinary meetings, he shall thereupon cease to be a Member of the Council, unless a reason for such absence satisfactory to the Council be assigned. (*c*) That not more than one-half of the Members of the Court of Examiners, and not more than two Members of the Board of Examiners in Anatomy and Physiology, shall have seats in the Council. (*d*) If any Fellow who is also a Member of the Court or of the Board of Examiners shall be elected into the Council, he shall, within a period of two months of such election, vacate his office as a Member of the Court or of the Board.

II. *Respecting the Conditions of Candidature of Fellows for the Council.*—Recommended: That Section 9 of Charter 15 Vict. do read as follows:—That every Fellow who shall intend to offer himself as a candidate for a seat on the Council of the said College shall, within such time as the Council shall from time to time direct from the publication of the *London Gazette*, in which the day of election shall be announced, transmit or deliver to the Secretary of the same College a notice signed by himself of such his intention.

III. *Respecting the Condition and Term of Tenure of the same Office.*—Recommended: (*a*) That the six Members of the Council, who shall have served longest on the Council without re-election, shall vacate their office every year instead of three, as provided for by Section 12 of Charter 7th Vict.

IV. *Respecting Substitute Members.*—Recommended: (*b*) That "Substitute Members," as defined by Section 14, Charter 7th Vict., be abolished.

V. *Respecting the Mode of Voting.*—Approved: The proposed alteration in the Section 15 of 7th Vict., abolishing compulsory personal voting, and permitting the alternative of voting by voting paper.

VI. *Respecting Payment of Fees by Members of Council.*—Recommended: The payment of a fee by a Member of the Council be no longer required.

VII. *Respecting the Election and Tenure of Office of President.*—Recommended: That the President of the College be elected annually by the Fellows from among the existing or past Members of the Council at the time, in the manner and under the conditions hereinafter described:—(*a*) That he be elected at the time and in the manner that Members of the Council are elected, on the nomination of the Council. (*b*) That the Council shall submit at least three names to the Fellows, one of which shall be that of the retiring President, provided he be eligible and does not decline to serve. (*c*) That no one shall hold the office of President for a longer period than five consecutive years. (*d*) If the President be elected from amongst the past Members of the Council, he shall become *ex-officio* a Member of the Council during his tenure of office as President.

VIII. *Respecting the Office of Treasurer.*—Recommended: (*a*) That a Treasurer be appointed from amongst the Members of the Council, and that his accounts be audited by a professional auditor, whose report shall be submitted to the annual meeting of Fellows and Members. (*b*) That the Treasurer's balance-sheet, duly audited, shall be submitted to the annual general meeting of Fellows and Members, and that such balance-sheet shall be published with the advertisements convening such meeting.

IX. *Respecting the Constitution of the Court of Examiners.*—Recommended: (*a*) That Members of the Court of Examiners shall be elected annually, and that no Member of the Court of Examiners shall hold office for more than five consecutive years. At the expiration of this time he shall not be again eligible until after a period of two years has elapsed. (*b*) That all vacancies in the Court of Examiners shall be advertised in at least two of the weekly medical journals of the United Kingdom, with an announcement of the names of those members of the Court who are eligible for re-election, and inviting Fellows desirous of being considered candidates to send in their names to the President. (*c*) That Section VIII. (3) of the Bye-laws requiring the

Digitized by Google

payment of a fee of twenty guineas by a person elected a member of the Court of Examiners be omitted.

X. *Respecting the Board of Examiners in Anatomy and Physiology.*—Recommended: That Members of the Board of Examiners shall be elected annually from amongst the Fellows and Members of the College, and that no Member of the Board shall hold office for more than five consecutive years, and at the expiration of this, his term, he shall not be again eligible until after after a period of two years has elapsed.

XI. *Respecting the Election of Fellows without Examination and of Honorary Fellows.*—Recommended: (*a*) That the alteration proposed by the Council in Section 5, Charter 15 Vict., be not adopted, and that the words "any two persons," read "not more than five." (*b*) That the Council may nominate distinguished members of the medical profession, whether Members of the College or not, as Honorary Fellows, to be elected by the Fellows and Members at the Annual General Meeting.

XII. *Respecting Meetings of Fellows and Members, separately and collectively.*—Recommended: (*a*) That there shall be an Annual General Meeting of the Fellows and Members at which the Annual Report of the Council, including the Treasurer's Statement of Accounts, duly audited, shall be presented, discussed, and if approved, adopted. (*b*) That no alteration in the constitution or in the relations of the College shall be effected without the consent of the Fellows and Members, convened specially to discuss such alterations. (*c*) That on receipt of a requisition signed by thirty Fellows or Members the President shall convene a meeting within twenty-one days of the Fellows and Members collectively (or, if demanded in the requisition, separately). At this special meeting or meetings the question or questions of which notice shall have been given in the requisition shall alone be discussed. (*d*) That such meetings shall be duly advertised in the weekly journals.

XIII. Recommended as a Bye-Law: That the Minutes of each Meeting of the Council shall be suspended for the inspection of Fellows and Members in the College Hall, or other convenient place, within twenty-four hours of the holding of such meeting, and that they remain suspended for a period of at least seven days.

THE CHOLERA EPIDEMIC.

WERE it not for the occurrences at Yport, in Normandy, and at Orancié, Algiers, the history of cholera in Europe and on the Mediterranean for the past week would have been one of steadily maintained abatement. Cholera news from the south of France has almost ceased. In Italy about twenty deaths still occur daily, but the diminution in mortality, both as regards the country generally and such cities as Naples and Genoa, is most satisfactory. So, also, the number of attacks in Spain has become so small that most of the inland quarantine restrictions have been removed, and even those at the ports have been so modified as to allow of a renewal of foreign trade transactions. But on October 21st news came of cholera at Yport, a fishing village between Fécamp and Etretat on the Normandy coast, and it appears that at least fifteen cases have occurred there, eight of the attacks being fatal. The first news pointed clearly to importation of the infection from the south of France, and it was explained that part of the crew of a Newfoundland fishing vessel having arrived at Yport from Cette, the disease began in a woman who washed one of the sailor's clothes, and then spread in a manner favourable to the theory that personal infection was in operation. Some doubt has, however, since been thrown upon the accuracy of the diagnosis in the first case, and there is an absence of any evidence to show that there had been any cholera at Cette, or that the crew in question had touched at any infected place, whether on the coast or inland; or again, that either of these had suffered from any choleraic symptoms. Still, the mere absence of news concerning these points is by no means conclusive against the disease being actually imported cholera, and the fact that no denial as to its alleged character comes in, even after the inquiry held by Dr. Gibert of Havre, must be regarded as showing that the first view expressed has been accepted in France. So abominable are the sanitary arrangements of Yport, the place being described as either a manure heap or a cesspool, according to the weather, and so filthy and drunken are the habits of the people, that either cholera itself would find in it ample means to favour its spread, or, on the other hand, any fatal form of specific diarrhœa might manifest itself there apart from the importation of the cholera contagium. An effort is being made to improve the more dangerous conditions under which the people are living, and it is to be hoped that these may successfully stay the outbreak.

As regards Algiers, it now transpires that cholera cases have occurred there for about a month past, and it is quite evident that, notwithstanding the stringency of the quarantine arrangements which have been maintained, the disease has found its way across the Mediterranean, and this, in all probability, in connexion with the shipment of troops from France. Oran, which is now reported to be infected, is in regular sea communication with Marseilles. The area of the 1884 epidemic has thus been again widened, and the transmission of the infection to a more southern climate may make the final eradication of the epidemic this autumn more difficult of accomplishment.

DR. TOMMASI CRUDELI ON MALARIOUS COUNTRIES, AND THEIR RECLAMATION.

THE last number of the *Nuova Antologia* contains an article on "Il Bonificamento dei Paesi di Malaria," by Dr. Tommasi Crudeli, well worth the attention of the practical hygienist.

Dismissing from scientific terminology the words "marsh miasm" and "marsh soil," and replacing them by "malaria" and "malarious soil," the author traces the fever poison thus indicated to "an agent which can infect the soil of any country, however that soil may differ from other soils in hydrographical and topographical conditions and geological composition."

This agent is a living organism inferred to exist long before microscopy. That its character should remain uniform in soils the most diverse proves that it cannot result from the chemical reaction of these soils. This persistent uniformity is easily understood on the admission that malaria is due to a fermentative organism which finds conditions favourable to its life and its multiplication in soils the most various, as is the case with thousands of other organisms much higher than the rudimentary vegetations which constitute living ferments.

The increasing intensity of the poison in malarious soils abandoned to themselves is especially demonstrable in Italy. Etruscan and Latin cities—Rome herself—arose in malarious regions, and they flourished mainly on account of the soil reclamation, which in the course of centuries diminished the production of the poison, without, however, succeeding in wholly suppressing it. The abandonment of the reclaiming processes led to the redevelopment of the poison—first during the Roman domination in the conquered and devastated Etruria, afterwards in Rome herself on the fall of the empire, and finally in Southern Italy. This redevelopment of malaria in the Roman Campagna has been witnessed in times not very remote from ours, localities where it was possible to enjoy summer residence (*villeggiatura*) having at that season become uninhabitable. In these localities the physical conditions of the soil have not varied for centuries; how, then, can the enormous increase of malaria be due to progressive alteration in the chemical constitution of the soil itself? Admit that malaria consists in a living organism whose successive generations infect to an ever-increasing extent the soil which contains it, and the explanation is easy.

Again, in regard to the malarious contents of the atmosphere. If the malarious ferment (*fermento malarico*) were composed of gaseous emanations from the soil, or of a chemical ferment formed in the soil and raised into the air together with watery vapour, the malarious contents of the atmosphere ought to reach their maximum in those hours when the soil is most warmed by the sun's rays and in which the evaporation of the water it contains and the chemical processes occurring within it are at their greatest intensity. But it is not so. The malarious contents of the local atmosphere are less in the noonday hours than at the

Digitized by Google

beginning and close of the day—that is, after sunrise and, above all, after sunset. Now, it is exactly at these two periods of the day that the difference between the temperature of the lower strata of the atmosphere and the temperature of the surface of the soil is greatest, and that the currents of air which ascend vertically from the soil into the upper atmosphere are at their strongest. Admitting that the malaria is formed of solid particles of low specific gravity (such as are the germs of the inferior vegetations), we see at once how it ought to accumulate in the lower strata of the atmosphere, especially in those two periods of the day.

The tendency among investigators has always been to attribute this specific poisoning of the air to a living organism which multiplies in the soil; but, unfortunately, the "palustral prejudice," as Dr. Tommasi Crudeli calls it, has led them to examine only the lower organisms which haunt marshes. In 1879 the author, in conjunction with Dr. Klebs, discovered the cause of malaria in a "schizomyces bacillaris," and recently Drs. Marchiafava and Celli have demonstrated that this parasite attacks directly the globules of the blood and destroys them after having determined in them a series of characteristic alterations, which indicate quite certainly the existence of a malarious infection. "Many observations," says the author, "just completed in Rome would tend to demonstrate that this parasite does not invariably assume the bacillary form described by Klebs and myself; but this purely morphological question need not concern the practical hygienist. For him it is essential to know that he has to deal with a living ferment which can flourish in soils the most diverse in composition, and without the presence of which neither marshes nor pools of putrescent water are capable of producing malaria."

Having incidentally shown that soils may contain this parasite in an inert state and not produce malaria till the circumstances favourable to its activity have arisen, Dr. Tommasi Crudeli proceeds to demonstrate that among the conditions which assist the development of the malarious ferment contained in the soil and the excessive air accumulation of that ferment in the air there are three of primary importance, as their concurrence is indispensable to the production of malaria. These are, 1st, a temperature not lower than 20°C.; 2nd, a moderate degree of permanent humidity in the malarious soil; and, 3rd, the direct action of the oxygen of the air on the strata of the soil which contains the ferment. If one only of these three conditions be wanting, the development of malaria becomes impossible. Now this is an important point in the natural history of malaria, as giving us the key to the chief part of the soil reclamation attempted by man.

First, let us take nature's amelioration of the malarious countries, suspending as she does for a longer or shorter time the production of malaria. Winter, for example, causes in all these countries a purely thermic amelioration—that is, it suspends the production of malaria simply by making the temperature fall below the minimum required for the development of the poison. In fact, there are often, even in winter, sudden outbreaks of malaria when a scirocco wind raises the temperature above this minimum. Again, during a very warm and dry summer malaria is not developed, because the sun's rays have exhausted the humidity of the soil, so producing a purely hydraulic amelioration, which, as in the Roman Campagna in 1881 and 1882, may last for a considerable time; easily to be dissipated, however, by one steady shower. Finally, there may occur in nature purely atmospheric ameliorations, when the surface of the malarious soil is withdrawn from the direct action of the oxygen of the air by means of natural earth-coverings formed by alluvial deposits of healthy soil, or by means of the "earth-felt" wrought up from the soil by the roots of herbage in a natural meadow.

In their various attempts to suspend the development of malaria from the soil men have tried to imitate nature—to eliminate, that is to say, one of the three conditions indispensable to the multiplication of the specific ferment contained in that soil. Naturally enough, they have never attempted thermic ameliorations, such as nature effects in winter, because it is not in their power to control the sun's rays. They have had to restrict their efforts to either hydraulic or atmospheric ameliorations; but sometimes they have succeeded in happily combining the one and the other—that is, in eliminating at once the humidity of the soil and the direct action of the oxygen of the air upon it.

Hydraulic amelioration has assumed many forms, according to the nature and site of the malarious soil. Drainage, in which the ancient Romans excelled us, has been practised in Italy both in deep and friable soils and in subsoils compact and almost impermeable, in which latter the "cunicular" drains of the Etruscans, Latins, Volscians, and Romans might even nowadays be studied with advantage.

Sometimes a twofold drainage of the upper, as well as the under, aspect of the soil may be practised—that is, draining the subsoil and increasing the evaporation of the surface water. The cutting down of forests in malarious countries has often proved an excellent means of amelioration; because by removing every obstacle to the direct action of the sun's rays on the surface of the soil, its humidity during the warm season is sometimes entirely exhausted. In spite of universal experience of this fact, a school originating with the great Roman physician, Lancisi, has sustained the contrary, counselling the maintenance and even the extension of forests in malarious countries. Lancisi was completely possessed with the "palustral prejudice," and believed that the malaria generated in the Pomptine Marshes, and attacking such townships as Cisterna, was intercepted, if only partially, by the forests between, and he therefore opposed the cutting down of the trees and recommended increased planting. He did not know that the malaria was already in the soil and covered by the forest in question. Some thirty years ago the Caetani family, to whom Cisterna belongs, cut down the forest, and twenty years thereafter Dr. Tommasi Crudeli was able to show that the health of the neighbourhood had greatly improved in consequence. A commission appointed by the Minister of Agriculture investigated the whole subject of the coexistence of woods with malaria, and in its report issued in 1884 completely disproved the theory of Lancisi and confirmed that of Dr. Tommasi Crudeli.

Absorbent plants have been suggested and used as a means of drawing humidity from the soil, not without success in certain countries really malarious. The prejudice that the malaria is due to the putrescent decompositions of the soil has, in Italy, led to the choice of the eucalyptus globulus as the tree best adapted to combat the poison, the idea being that the eucalyptus, which grows very rapidly, dries the humid earth, and at the same time by the aroma of its leaves destroys the so-called miasmata. No genuine instance of the eucalyptus having succeeded in its allotted task is yet known to Dr. Tommasi Crudeli, though he does not say that its success is impossible. Had its Italian patrons studied its action in its native Australia where it flourishes much better than in Italy, they would have known that there are eucalyptus forests in those latitudes where malaria is very prevalent, as has been shown by Professor Liversidge of the University of Sydney. The cultivation of the tree at the Tre Fontane, near Rome, which it was thought would prove entirely successful in combating the local malaria, disappointed expectations, for in 1882 that hamlet was the scene of a severe outbreak of the fever, while the rest of the Campagna was unusually exempt from it. The eucalyptus, in fact, is a capricious tree in European soil; while in full leaf, during the winter, it is often killed by nocturnal frost, and even by the late frosts of spring, to say nothing of humid cold and other adverse influences not yet formulated by the botanist; again, when the winters are mild and the soil deep, it often shoots up rapidly, only to be snapped asunder by winds of moderate strength. Eucalyptus plantations, moreover, are very costly. If the ground is watery, it has to be drained, otherwise the roots rot; if the ground is heavy, trenches must be dug in it to make room for the long roots of the trees, and often these trenches have to be drained, as is done in the case of olives, in order to prevent the filtration water from stagnating and the roots from rotting. Hydraulic amelioration must have recourse to means less uncertain; and should the conditions of any locality counsel a trial of an absorbent plantation, it should be done with trees of our own hemisphere. The expense is smaller, and the trees are sure not to die.

At best, hydraulic amelioration is never certain, because the slight humidity of the soil necessary to develop malaria may easily be restored to it, even during the warm season. Combination of atmospheric with hydraulic amelioration has therefore been tried: to withdraw, that is to say, the humidity from the soil, while at the same time preventing the direct contact of the air with its malarious strata. Leaving the soil with layers of sound earth spread over it either alluvially or by the hand of man, and also draining the soil itself, was last year, at the instance of Dr. Tommasi Crudeli, practised on the grounds of the Janiculan Hill, near the Palazzo Salviati, in the Lungara. The entire area,

Digitized by Google

having been thoroughly well drained and then covered with a dense coating of meadow soil in all those places which could not be paved with street rubble, has since remained without a single case of fever in the numerous *personnel* of the Military College occupying the Palazzo Salviati, while in the Palazzo Corsini, on the same side of the Lungara, but looking on the grounds of the Janiculan which are still exposed to the air and sun, there have within the same period been not a few cases of fever, some of them fatal.

THE WOUNDED AT FOOCHOW.

DR. T. B. ADAM, Surgeon to the Foochow Native Hospital and Dispensary, has favoured us with the following interesting description of some of the cases which came under his care or observation as the result of the recent engagement at that port:—

As over fifty men, wounded in the late so-called naval engagement at Pagoda Anchorage, Foochow, came under charge of Dr. Rennie and myself as patients in the Foochow Native Hospital, it struck me that a brief notice of the most important of our cases might interest your readers. The engagement took place on Saturday, Aug. 23rd. A goodly number of wounded, carried down the river by the strong current and ebb tide, were rescued by the boats' crews from H.M.S. *Vigilant*, *Sapphire*, and *Champion*. Those who managed to reach the shore dragged themselves to deserted Chinese houses, and lay there utterly untended and uncared for, as far as the Chinese Government was concerned. On Monday a party of us from Foochow picked up eleven of these poor wretches, all very seriously wounded and in a most miserable condition. These, along with the cases rescued by Her Majesty's ships, were placed in the Native Hospital. Every flood tide thereafter brought, through native sources, fresh additions to the number, till our list rose to over fifty. The great majority of our cases presented wounds inflicted by Hotchkis's shells. The severe nature of such wounds, together with the terrible after-neglect, made our death list heavy. Six cases succumbed within a fortnight. They were as follows:—

1. Right leg shattered by a shell; total neglect for forty-eight hours. Amputation through knee-joint. Died two days after operation from sheer prostration.

2. Knee-joint traversed by fragment of shell; total neglect for forty-eight hours. Dressed antiseptically and wound tolerably healthy; but death from prostration ensued six days after admission.

3. Extensive burn of face and body from gunpowder explosion on board a war junk. Death from collapse.

4. Forearm shattered by a shell; total neglect for six days. Hand and forearm black on admission; amputation performed in lower third of arm. Recovered well from shock, but one flap showed signs of sloughing. Eight days after operation secondary hæmorrhage occurred. Patient was dozing at the time and much blood was lost before he called his attendant's attention to the accident. Before an assistant could be obtained and a tourniquet applied, patient was in a fatal swoon. Such an occurrence would be rare in a home hospital, but we have to make the best of the native material afforded us for nurses and assistants.

5. Patella shattered by fragment of shell, and knee-joint laid open. Broken fragments of bone were removed and wound dressed antiseptically. Locally all seemed to go well, but a low form of surgical fever exhausted patient's feeble reserve of strength, and he succumbed nine days after admission.

6. Compound comminuted fracture of both bones of leg with much destruction of soft parts; total neglect for four days. Patient would not permit amputation, but gangrene setting in a day or two after admission the limb was removed through the middle of the thigh. Skin of flaps looked perfectly healthy, but a portion of the cellular tissue was observed to be ominously dark-coloured. For four days the patient did well, acute gangrene then suddenly set in, followed by death from exhaustion within twelve hours.

Among cases of severe wounds progressing favourably the following may be noticed:—

1. Shattered leg; amputated just below knee very shortly after receipt of injury, by Dr. Biddulph of H.M.S. *Vigilant*. Patient had by no means a vigorous constitution, but shock rapidly passed off, and wound healed almost by first intention.

2. Compound comminuted fracture of humerus with great destruction of soft parts. Amputation performed in upper third; dressed antiseptically and doing well.

3. Knee-joint traversed by fragment of shell. Acute pain occurred for a few days in joint, but this subsided and the case is now doing well; dressed antiseptically.

4. Compound comminuted fracture of humerus in middle third. Dressed antiseptically and doing very well.

5. Elbow-joint traversed by fragment of shell and lower end of humerus splintered. Resection of ends of humerus and ulna performed. Dressed antiseptically and doing well.

6. Compound comminuted fracture of left humerus, and right elbow-joint penetrated by fragment of shell. This man was shot while in the water, with his arms extended over a floating spar. As the French were accused of cruelly firing upon disabled Chinese in the water I made careful inquiries among our patients, and think the following statement the correct one. After the first broadside delivered by the French a large number of many of the Chinese gunboats' crews leaped overboard and struck out lustily for the shore. These men were fired on from the "tops" of the French vessels, but these alone. The French themselves, I was informed, rescued some twenty wounded Chinese and treated them on board.

7. Hand split in two by bursting of gun. The forefinger with metacarpal bone was carried away, the first carpo-metacarpal joint laid open, and fully one-third of soft parts of back of hand destroyed. Sloughing tissue was pared away and wound dressed antiseptically. Healing is rapid, and patient will retain a useful hand.

8. A bugler, twenty years old, was struck while in the water by the cup of a Hotchkis's shell. The brass-headed fragment entered at the lower part of the hip, passed round the inner side of the femur, splintering but not fracturing it, and lodged in the groin, just inside of the femoral vessel. The lad was eleven hours in the water before he was rescued. He is but slowly recovering from the shock. A large perforated drainage-tube has been inserted through the wound from the groin to the hip, and gives free exit to discharge from sloughing tissue in the track of the fragments of the shell.

9. Splinter of shell entered left eye. Immediate enucleation saved the right eye from sympathetic inflammation.

10. A poor salt junk sailor, who did not want to fight, but was impressed into the service, received, as his only reward, a fragment of shell in his back. Glancing off the middle dorsal spines, the fragment buried itself laterally in the long muscles of the back. A few days after extraction an abscess formed over the hip, and this, on being opened, was found to communicate freely with the wound. Doing well.

11. A chair coolie ashore received a shot from some careless soldier. The bullet entered the great sacro-sciatic foramen and disappeared in the pelvis. A probe can be passed into the wound for about ten inches upwards in front of the sacrum towards the abdominal cavity, but no bullet can be found. A large drainage-tube has been inserted, and the wound dressed antiseptically. The abdomen has become somewhat swollen, but is not painful on pressure. The future of this case will be an interesting study.

12. Compound transverse fracture of head of tibia with open knee-joint. Dressed antiseptically, the case did well, but after a week's residence in the hospital the patient went off to headquarters to bespeak his pay. Warning of loss of limb or life could not deter him. Such cases are no unusual feature of Chinese practice.

Five cases of traversing wounds of the thigh all progress favourably. In one case a fragment of shell sliced off a portion of the anterior surface of the thigh, leaving an excavated saucer-like wound. Our remaining cases include traversing wounds of shoulder, forearm, calf, ankle-joint, &c.; burns from explosions of gunpowder; compound fractures of bones of the leg, &c., with details of which I must not trespass further upon your space.

Foochow, Sept. 5th, 1884.

A MEDICAL PRESIDENT.—Dr. Don Rafael Zaldivar, President of the Republic of San Salvador, is reported, says the *New York Medical Record* of October 18th, to be a very accomplished physician. He has just been chosen for a third term, and is now travelling in Europe.

WILLS OF MEDICAL MEN.

THE will of Cæsar Henry Hawkins, F.R.C.S., F.R.S., serjeant-surgeon to the Queen, late of 26, Grosvenor-street, who died on July 20th last, was proved on the 23rd ult. by Mrs. Ellen Hawkins, the widow, the sole executrix, the value of the personal estate exceeding £45,000. The testator bequeaths the bust of himself by Mr. Richard Halse, presented to him by his former pupils, to his wife for life, and then to the governors of St. George's Hospital, to which he had been so long officially attached; the portrait of his late uncle, Mr. Pennell Hawkins, by Loffany, to his wife for life, and then to the Royal College of Surgeons, to be placed near the picture of his brother, Sir Cæsar Hawkins, by Hogarth; and his medical books (except such as may be selected by his wife) to the Students' Library of St. George's Hospital. He also bequeaths his stocks and shares in the Great Northern Railway upon trust for his wife for life; at her death numerous legacies are to be paid thereout, and out of certain moneys in settlement to his brothers, sister, nephews, nieces, and others, and the remainder of the same funds is to be divided between his nephew and niece, Cæsar Richard Hawkins and Mary Frances Hawkins. There are legacies to his trustees, and the residue of his property he gives to his wife absolutely.

The will of John Carnegie, M.D., late of Chesterfield, Derbyshire, who died on May 4th last, was proved on the 29th ult. by Mrs. Agnes Diana Knight Carnegie, the widow, Mr. Andrew William Manson, and Mr. James Bruce, the executors, the value of the personal estate amounting to over £11,000. The testator leaves his plate, books, pictures, furniture and effects, and £100 to his wife; and the residue of his real and personal estate upon trust for her for life or widowhood. If his wife marries again, one-third of the income is to be paid to her; subject thereto the residue is to be equally divided among his children.

The will of Thomas Bishop, M.D., F.R.C.P., late of 16, Rue Pierre Charron, Champ Elysées, Paris, and of Hayne Croft-road, Torquay, who died on June 23rd last, was proved on the 16th ult. by Mrs. Cecilia Agnes Bishop, the widow, and Miss Effie Rose Bishop, the daughter, the executresses, the value of the personal estate amounting to over £8000. The testator leaves £100 to Mrs. Mary Peel, free of duty; £200 per annum to his said daughter during the life of his wife; and the remainder of the income of his property to his wife for life. At her death he gives the residue of his property to his daughter.

The will of Hugh Cuolahan, M.D., late of 9, Grange-road, Bermondsey, who died on August 20th last, was proved on the 12th ult. by Mrs. Maria Carolina Cuolahan, the widow and sole executrix, the value of the personal estate amounting to over £4000. The testator gives, devises, and bequeaths all the real and personal estate which he shall be possessed of or entitled to at the time of his decease to his wife.

The following legacies have recently been left to hospitals and other medical institutions:—Mr. William Robert Mitchell, late of the Stock Exchange, and of 14, North-terrace, Camberwell, £1000 to the Middlesex Hospital.—Mr. Thomas Browning, formerly of Hatton-court, Threadneedle-street, and of 6, Whitehall, but late of Queen Victoria-street, fifty guineas each to Charing-cross Hospital, the Hospital for Consumption and Diseases of the Chest, Brompton, and the Cancer Hospital, Brompton.—Mr. Edward Samuel Dowling, late of 14, Holland-villas-road, Kensington, £500 to the North London or University College Hospital on the death of his wife.

THE WATER-SUPPLY OF DUMFRIES.—On the 10th inst., Dr. J. M. M'Culloch delivered the first of a second course of health lectures which it is proposed to hold during the present winter in Dumfries. The subject of the lecture was "Water: use in the body; water suitable for domestic use, with special reference to Dumfries water-supply; effects of impure water," &c. In the course of his address Dr. M'Culloch recommended that the future water-supply of the town should be derived from loch Grennoch, a source which he described as eminently suitable for such a purpose.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On the Prevalence of "Fever" in Burnley, by Dr. AIRY.—For some years past the general death-rate of Burnley has been high, the mean for the past thirteen years being 24·4 per 1000. During the same period the "fever" death-rate has also been excessive. In the four years 1870–73 it was especially high, then came a marked diminution, but from 1881 onwards it increased again. At first there appeared grounds for fearing that the fever in question was typhus, but apart from cases which seem to have been incorrectly certified, the prevalent disease has clearly been enteric fever. The most recent epidemic of this disease commenced in October, 1882, during which month nine deaths were registered as due to it, and from that time forth until February of this year fatal cases followed each other with very little abatement. Dr. Airy found it impossible at the date of his recent inquiry to trace the commencement of the epidemic to its proper source, although this should have been possible when the outbreak commenced, especially in the face of the sudden character of its onset. But speaking generally, both as regards the early and later history of the prevalence, the evidence went strongly to connect it with the presence of excremental nuisances and defective drainage. Burnley has done good sanitary work since 1870; it has a wholesome water service, and a new system of sewers. But the house connexions with the new sewers are in some cases faulty, and in their effort to do away with the old and offensive midden-privy the Corporation have fallen into error. It is to this that Dr. Airy principally draws attention, and it is evident that with this he mainly connects the outbreak under discussion. Between seven and eight thousand tank privies have been provided in the borough. The tank is an earthenware one containing either nine or sixteen cubic feet of contents. It is sunk in the ground at the back or the side of the privy with an earthenware cone placed under the seat, fitting into a bay in the rim of the tank, and about six inches below the rim on one side there is an overflow pipe, communicating with the inside of the tank by a cluster of eight holes to convey the top fluid to the sewer. Now, like nearly all such overflows, this grating is apt to get stopped, as, for example, by means of floating pieces of paper; but apart from this, the existence of an overflow is in itself absolutely wrong in principle. If drains and sewers are available and fit for the removal of the offensive overflow liquid from a privy pit, there can be no justification whatever for retaining nine and sixteen cubic feet of excreta close to dwellings. The whole contents of the closet should, in short, go to the sewers, and not the surface fluid only. But, as has often been pointed out, the passage into the sewers of privy pit liquid which has been retained long enough to decompose and become offensive, causes nuisance and a foul state of drains and sewers, and it is because this is so well known that modern bye-laws nearly all prohibit any connexion between a privy and a drain. There are other points about the Burnley privy which, though arranged with the best intention, have not turned out satisfactorily, and it is to be hoped that in a borough of 64,000 people the Town Council will now discountenance the storage under any circumstances of from nine to sixteen cubic feet of excremental filth at some 7000 points in the district. Dr. Airy advocates the trough closet system, and that form of closet is found to work well when provided with the automatic system of flushing, such as is now being exhibited at South Kensington by Messrs. Bowes, Scott, and Read; the plan is not only admirably adapted to the dwellings of the lower classes, but it is economical in its working. One other fault in the sanitary administration of Burnley lies in the fact that the medical officer of health is not provided with an immediate notice when a death from infectious disease occurs. This is the more strange when coupled with the fact that although under the Burnley Improvement Act, 1883, a system of compulsory notification was provided, yet when Dr. Airy made his report in July last, no steps whatever had been taken to carry it into effect. Much work has been done in

Digitized by Google

Burnley, and it is to be hoped that the future action taken will be in such directions as to reduce the excessive mortality from enteric fever which has so long prevailed there.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

St. Pancras.—Estimating the population of this metropolitan parish at 239,174 for 1883, Mr. Shirley Murphy reports an exceptionally low birth-rate of 32·2 and a death-rate of 20·7 per 1000 living. Only thirteen cases of small-pox were heard of, and vaccination is carried out with great efficiency. Indeed, there is not a single birth remaining quite unaccounted for during the latter half of 1882, and there are only three outstanding cases amongst the children born in the first half of 1883. Speaking of scarlet fever, Mr. Murphy points out some of the conditions under which it was found to spread, and he records a case in which a family of four were occupying the single room they possessed together with a scarlet fever corpse. Such conditions as these, he urges, show strongly the need for proper mortuary accommodation, and it is certain that so long as the only mortuary is at the workhouse, where it is surrounded with all the degrading associations of pauperism, the population cannot be educated to understand the value which attaches to the early removal of the dead from amongst the living. Enteric fever caused 132 deaths in 1883, this being nearly 78 more than the average number for the preceding ten years. The cause of the large outbreak which attacked 431 persons will be remembered in connexion with Mr. Murphy's inquiry in the autumn of last year into the circumstances of a dairy farm near St. Albans, the milk from which was unquestionably shown to have been the vehicle of infection. In connexion with the infant mortality, Mr. Murphy presses the vestry to make regulations as to tenement houses, and he urges that until they have done so they will not have exercised to their full extent the powers they possess for improving the condition of their poorer parishioners. We note with much regret that this important matter receives but tardy attention at the hands of some metropolitan authorities. Mr. Murphy would gladly see fresh legislation on this subject, and he points out that if, in default of the immediate owners of tenemented property maintaining their houses in proper condition, as by neglecting to carry out the repairing clauses of leases, they could be made to forfeit their leases, houses that are occupied by the very poor would not continue to be owned by those who are unwilling or unable to maintain them in a proper habitable condition.

Limehouse.—In the Limehouse district the birth and death-rates for 1883 were 25 and 38 per 1000 respectively. The sewer ventilators in several parts of the district have been a constant source of complaint, and a new system is now being attempted at some of the principal points. Some measures are also being taken to do away with some of those conditions of housing which are a disgrace to the metropolis. After several efforts at improvement, Elizabeth-court has been closed under a magistrate's order. An area in Shadwell, too, has been reported to the Metropolitan Board of Works under the Artisans and Labourers Dwellings Act, 1875. Many of the houses are built back-to-back, most of them are in a very bad structural state, and the death-rate for the last three years has averaged 44 per 1000. In other localities either works of alteration and improvement or actual closure of houses is going on; but it is evident from the description given by Mr. Rogers that much more is needed in this direction than he is at present able to effect.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

During the week ending the 25th ult., 5986 births and 3517 deaths were registered in twenty-eight of the largest English towns. The annual rate of mortality in these towns, which in the two preceding weeks had been 19·8 and 21·1 per 1000, declined last week to 20·9. During the past four weeks of the current quarter the death-rate in these towns averaged 20·5 per 1000, against 20·9 and 19·6 in the corresponding periods of 1882 and 1883. The lowest rates last week in these towns were 16·1 in Portsmouth, 16·5 in Sunderland, 18·4 in Birkenhead, and 18·7 in Plymouth. In the other towns the rates ranged upwards to 25·4 in Bolton, 26·1 in Manchester, 28·4 in Liverpool, and 31·5 in Preston. The 390 deaths referred to the principal zymotic diseases in the twenty-eight towns included 105, which resulted from diarrhœa, 66 from scarlet fever, 66 from "fever" (principally enteric), 55 from measles, 46 from whooping-cough, 32 from diphtheria, and 19 from small-pox. These diseases caused the lowest death-rates in Norwich and Plymouth, and the highest in Cardiff, Preston, and Derby. The highest rates of mortality from scarlet fever were recorded in Newcastle-upon-Tyne and Halifax, from measles in Cardiff, from whooping-cough in Bradford and Salford, and from "fever" in Preston, Leeds, and Derby. The 32 fatal cases of diphtheria in the twenty-eight towns included 22 in London, 2 in Brighton, 2 in Liverpool, and 2 in Birmingham. Small-pox caused 15 deaths in London (exclusive of 6 London cases registered outside Registration London), 1 in Wolverhampton, 1 in Birmingham, and 1 in Hull. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had been 504 and 558 at the end of the two preceding weeks, further rose to 596 on Saturday last; the cases admitted were 173, against 68 and 144 in the two previous weeks. The Highgate Small-pox Hospital contained 20 patients on Saturday last, 6 new cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which in the five previous weeks had increased from 159 to 286, declined to 274 last week, and were 92 below the average. The causes of 75, or 2·1 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of deaths were duly certified in Portsmouth, Leicester, Plymouth, and in three smaller towns. The largest proportions of uncertified deaths were recorded in Bristol, Oldham, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 22·8 and 21·3 per 1000 in the two preceding weeks, was 21·4 last week, and exceeded by 0·5 per 1000 the mean rate during the same period in the twenty-eight large English towns. In the Scotch towns the rates last week ranged from 14·8 and 17·1 in Leith and Greenock, to 24·9 in Paisley and 25·0 in Glasgow. The 317 deaths in the Scotch towns included 22 which were referred to measles, 21 to diarrhœal diseases, 19 to scarlet fever, 17 to diphtheria, 15 to whooping-cough, 15 to "fever," and 1 to small-pox; in all, 110 deaths resulted from the principal zymotic diseases, against numbers declining from 137 to 101 in the three preceding weeks. These 110 deaths were equal to an annual rate of 4·6 per 1000, which was double the average rate from the same diseases in the twenty-eight English towns. The 22 fatal cases of measles exceeded by 4 the number in the previous week, and included 12 in Glasgow. The 21 deaths from diarrhœal diseases showed a further decline from recent weekly numbers. Of the 19 fatal cases of scarlet fever, 13 were returned in Glasgow. The deaths referred to whooping-cough, which had been 20 and 18 in the two preceding weeks, further fell to 15, of which 8 occurred in Glasgow and 3 in Edinburgh. The deaths from "fever" showed a slight increase; 8 were returned in Glasgow and 3 in Paisley. A fatal case of chicken-pox (which in Scotland is classed as small-pox) was recorded in Glasgow. The 85 deaths referred to acute diseases of the respiratory organs in the eight Scotch towns showed a decline, and were 16 below those returned in the corresponding period of last year. The causes of 82, or nearly 16 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which in the three preceding weeks had increased from 26·3 to 30·2 per 1000, declined to 26·8 during the week ending the 25th ult. During the first four weeks of the current quarter the death-rate in the city averaged 28·0 per 1000, the rate for the same period not exceeding 16·4 in London and 17·6 in Edinburgh. The 180 deaths in Dublin last week showed a decline of 23 from the number in the previous week, and included 29 which resulted from the principal zymotic diseases, against 49, 32, and 25 in the three preceding weeks; of these, 12 were referred to scarlet fever, 7 to diarrhœa, 6 to "fever," 3 to whooping-cough, 1 to diphtheria, and not one either to measles or small-pox. These 29 deaths were equal to an annual rate of 4·3 per 1000, the rate from the same diseases being 1·7 in London and 2·5 in Edinburgh. The fatal cases

Digitized by Google

of scarlet fever, which in the two previous weeks had been 11 and 5, rose to 12 last week. The 7 deaths from diarrhœal diseases showed a further decline from recent weekly numbers, and the fatal cases of "fever" were 4 less than those recorded in the previous week. Five inquest cases and 6 deaths from violence were registered during the week, and 56 deaths occurred in public institutions. The deaths both of infants and of elderly persons showed a decline from the numbers in the previous week. The causes of 18, or 10 per cent., of the deaths registered during the week were not certified.

Correspondence.

"Audi alteram partem."

THE LATE DR. RABBETH.

To the Editor of THE LANCET.

SIR,—The exemplary, generous, and fatal devotion of Dr. Samuel Rabbeth to the duties of his profession has added his name to the list of our medical heroes. We should all be losers if his example were forgotten. It suggests itself therefore to me that a gold medal, bearing Dr. Rabbeth's name, and to be annually awarded to a Bachelor of Medicine of the University of London, on terms to be hereafter considered, might be a suitable memento of his heroism, as of that of many others. I cannot doubt that the Senate would gladly become trustees of any fund for such a purpose, and charge themselves with the duty of awarding the medal. I shall gladly contribute to any such fund.

I am, Sir, your obedient servant,

WILLIAM W. GULL.

Brook-street, Grosvenor-square, W., Oct. 27th, 1884.

P.S.—The question whether such risk need have been incurred is quite another matter, and upon which I will write later.

CORROSIVE SUBLIMATE AS A SURGICAL DRESSING.

To the Editor of THE LANCET.

SIR,—In his address on this subject Sir Joseph Lister called attention to the irritating properties of the sublimate solution in a case of amputation of the mamma. He says, "On the day after the operation, when we changed the dressing, I found that under the oiled silk, exactly corresponding to its extent, the skin was highly irritated, and was covered with small vesicles. I also found that the inner side of the arm, where there was no wound, was in the same state of intense irritation." The explanation of the latter he gives as follows:—"In the case of the arm what occurred was, free perspiration had taken place, and the perspiration forming with the corrosive sublimate in the gauze, a watery solution had produced irritation where the perspiration was, on the same principle as the watery solution had caused irritation under the protective." Whatever may have been the cause of the eruption under the protective, it appears to me that the cause of the irritation in the arm is to be found in the irritating properties of the eucalyptol, and the following case seems to confirm this view.

On April 28th last I removed the mamma of a woman aged thirty-four, and cleared out the axilla. According to my usual practice, the operation was performed without any antiseptic. The wound was immediately covered with thymol gauze, which I prefer on account of its absorbent property; over this was placed a thick pad of absorbent wool (Von Bruns' Red Cross), and these dressings were kept in place by a many-tailed bandage of eucalyptol gauze—a method which I would commend to the notice of surgeons instead of the old-fashioned plaster and roller bandage. The left bare arm lay on the chest in contact with the gauze. On the following day, corresponding exactly with Sir Joseph Lister's case, the arm was intensely irritated, and the limits were those of direct and close contact with the gauze. So great was the irritation that near the wrist the vesicles coalesced, and in the course of another day alone formed a blister as large as a half-crown piece. After the second day, of course, the skin was protected from the gauze. On the skin of the body there was very little effect produced, probably on account of its greater power of resistance. The wound, which, with one-half of the chest, was protected by the thymol gauze and wool, healed by first intention and without a blush, as I am accustomed to see it; the tube, on its removal on the fifth day for the purpose of clearing and shortening, contained a beautiful specimen of organised blood-clot, which is now before me, and the patient went home quite well on the fifteenth day.

Here, then, there could be no doubt as to the cause of the irritation, and I would suggest that the same cause operated in the case in question, rather than that the sublimate should have passed through the "abundant eucalyptus dressing," which was put on outside the sublimate gauze.

I am, Sir, yours faithfully,

GEO. GRANVILLE BANTOCK.

Granville-place, W., Oct. 28th, 1884.

THE COLLEGE OF SURGEONS EXAMINATIONS.

To the Editor of THE LANCET.

SIR,—At a time when there is a probability of the coalition of the Colleges of Physicians and Surgeons it may be opportune to express the views of a teacher on what he considers the unsatisfactory results of the College of Surgeons examination. It has become a trite saying amongst students "that there is no disgrace attending a rejection by the College of Surgeons, since the examination is of such a fluky character." I put this in the words of one who had recently obtained his membership, and I believe it echoes the sentiments of a considerable number of teachers as well as students. I speak as a teacher when I say that I think the College of Surgeons examination is a most unfair one, for I am perfectly certain that it often rejects very good men, whilst inferior ones are occasionally allowed to pass. At present it is impossible for any teacher to send up his pupils with confidence; for he feels that it is almost as likely that the better men will be referred and the worse accepted, as that the weak student will be rejected and the good one pass. To the London student this may perhaps be no very great hardship, for if there be no great loss of prestige he has not been put to much expense, and possibly no one knows that he has been in for an examination; but to the provincial student no little inconvenience ensues, for the necessity of a several days' absence in London compels him to acquaint his friends and puts him to a considerable amount of expense; thus to the financial loss is added the multiplication of friendly condolence. If the rejections were just I should be the last to protest against them, but I am convinced that many referred candidates are extremely well up in their work, and have been rejected from simple nervousness, the time allowed being too short and the examiners too hasty to elicit the knowledge, which though present is incapable of being roughly extracted. To mention a few examples:—

Of two students, one, rejected several times for his primary, and again for his final, advised by his teachers not to go for examination, proceeds to London with a gentleman who had passed his primary creditably, had done well at the school, had acted as resident assistant house-surgeon for a year, where he was highly appreciated for his good work and was advised by his teachers to enter his name for the final. Result: the former passed, the latter was referred, and, strange to say, only in the subject which it was well-known he knew best—viz., surgery. A medalist in all the subjects of examination was referred for six months. The medalist of the year in anatomy and physiology, but a reticent, somewhat shy man, was rejected; whereas several, whom he was head and shoulders above in knowledge of the subjects, passed. A qualified practitioner, well acquainted with his work and known by his teachers to be extremely well up, was rejected because he could not recognise a pathological specimen, and so by losing the greater part of the ten minutes allotted for this section, getting a bad mark and spoiling an otherwise good examination. An excellent student, as proved by school and clinical examinations, was rejected, and yet very shortly afterwards was able to obtain his final M.B. at one of the universities. Were it necessary, the above list could be increased, but I think these cases are sufficient to show that there is some ground for complaint. Where does the fault lie 1. With the hurried character of the examination—e.g., ten minutes for pathology, which time is utterly inade-

Digitized by Google

quate for the examiner to elicit more than one or two points of such an extensive subject; and which ten minutes may be entirely wasted by trying to make a student recognise something which the examiner has himself had to ask the curator the nature of before he began the examination. This is a fact which, to my knowledge, occurred some time ago. The time for the *viva voce* should be considerably increased, so as to give a nervous student the chance of collecting his thoughts; it is manifestly unjust that any man who knows his subject should be rejected simply because he is rather slow in answering under excitement; but at present an examiner cannot give him the time, since only a few minutes elapse before he has to take another student, and if the unfortunate candidate happens to bungle a little over his first specimen or case, there is no possibility of making up for lost time. 2. The system of marking is essentially a bad one, and might be easily remedied. 3. Those who have gone through the portals of the two Colleges in London cannot fail to contrast the courteous and gentlemanly treatment they receive at the College of Physicians as compared with the hurried rush through customary at Lincoln's-inn-fields. I am, Sir, yours truly,

A. W. MAYO ROBSON, F.R.C.S. Eng.,
Oct. 1884. Hon. Surgeon, Leeds General Infirmary, &c.

"THE SINS OF THE SOUTH-WESTERN."

To the Editor of THE LANCET.

SIR,—The shortcomings of the London and South-Western Railway Company have recently been the subject of some censorious comments in *The Times*. Permit me to point to a medical aspect of its shortcomings.

A large area of the south coast, embracing many of our most famous seaside resorts, especially winter health resorts, is more or less completely under the sway of this railway company. I should have liked to have written "served" by it, but "commanded" is the most appropriate term. A very large section of its best-paying patrons are invalids and persons suffering under bodily infirmities—persons indeed in every sense worthy of consideration. Yet what does this line do for the comfort or convenience of these travellers?

At no station is a space of time greater than three minutes allowed to the passengers. Other lines have certain places where the stay is five or even ten minutes, whether the train be late or punctual. What these three minutes may mean at times is an indefinite space, and after having bustled the passengers into the train a space of time is wasted before starting, which, if allowed to the passengers, would have made all comfortable. This line has a slow rate of speed, and studies but little the comfort of its patrons, yet it is notoriously unpunctual. Where is the time lost? The answer is, On the runs betwixt station and station. Its rate of speed is not so great but that it might "make up" time on this run, instead of "losing" more. Its unpunctuality is not due to the study of the convenience of its patrons, but to bad working arrangements. It is not good for invalids, in my opinion, to be kept unduly in railway carriages, either as to mind or body. This is one sin.

Let me furnish another instance of its care (?) of its passengers. Having a lady in delicate health in charge, it was thought desirable to reach Waterloo in good time in order to get comfortably seated for the journey. What was the result? We had to wait amidst an increasing crowd till five minutes from the time to start, when the train was backed in, and the crowd on the platform rushed to their seats—the weakest getting the worst places. Surely the rules of other companies might be followed on a line so very largely—if unavoidably—used by invalids. Yet another instance of their study (?) of the comfort of their passengers. A medical *confrère* assures me that it is not two years since a lady in infirm health had to be moved from the south coast to London. The South-Western had no invalid carriages, and one had to be procured from the Great Northern Railway Company. Yet this line and the seaside resorts long its route are largely maintained by invalid visitors, whose comfort ought to deserve some study. Many others are deterred by "the journey." Nature has done much for the south coast, but it cannot be said that the London and South-Western Railway Company does much to second her efforts. It is cruel to treat the weakly as it habitually does.

I remain, Sir, yours faithfully,
October 28th, 1884. J. MILNER FOTHERGILL.

NEWCASTLE-ON-TYNE.

(From our own Correspondent.)

PRESENTATION TO THE MAYOR OF NEWCASTLE.

A LARGE number of leading citizens, including several prominent members of our profession, assembled in the council chamber of our City Hall last week to witness the presentation to our mayor, Mr. H. W. Newton, surgeon, in recognition of his valuable services on the late visit of the Prince and Princess of Wales. The testimonial, which was subscribed to by all classes in the city and its vicinity, took the form of a massive and very handsome candelabrum, forming an epergne for flowers, &c. beautifully designed in the Renaissance style, the base being surmounted by four finely modelled figures, emblematical of the seasons, with side pieces for fruit in the same style of ornamentation, and decorated with figures symbolical of fishing, shooting, &c. There was also presented to the mayoress—who, as the deputy mayor, Mr. T. L. Gregson, surgeon, who presided, said, "had so ably seconded the mayor in every effort in his public capacity"—a very handsome case of brilliants and earrings, with a large diamond brooch, "which he hoped she would long have strength and happiness to wear." The deputy mayor remarked that he felt proud that a colleague of his own profession had held the office of mayor on the Royal visit, and still more proud of his success; indeed, the Royal visit would appear to have produced the happiest effects here in the way of binding all classes together to make the occasion worthy of the North.

DARLINGTON HOSPITAL DISPENSARY.

A bazaar and fair in aid of the new hospital building fund was opened at Darlington a few days since by the Duchess of Cleveland. It is estimated that the new hospital will, with all necessary appliances, cost at least £10,000. Beyond this it is desirable to provide at least £5000 for an endowment fund. Towards this sum of £15,000, £9500 has already been promised. The present annual expenses amount to about £1250, and the income, which is always liable to great fluctuations, does not exceed £1100. In the new hospital the expenses will necessarily be increased by £300 or £400 per annum. A good deal of interest has been taken by the public press in this effort, and I hope to be able to report to you some very satisfactory results from the bazaar.

ALNWICK INFIRMARY.

At the annual meeting, just held, Earl Percy presiding, an increase was reported in the number of patients admitted, but it was mentioned as a hardship on the subscribers that eleven of the in-patients were connected with the construction of the Alnwick and Cornhill Railway, and that their share of the expenditure amounted to about £40, while the only additional subscription received from the contractors was £5 5s. It appeared clear to the committee that the institution could not continue to admit such patients unless a much larger sum was paid on their account. The committee also expressed their pleasure with the way in which Dr. Davidson had performed the duties of house-surgeon during the year.

Newcastle-on-Tyne, Oct. 27th.

EDINBURGH.

(From our own Correspondent.)

THE WINTER SESSION.

THE winter session opened on Tuesday both in the University and Extra-Academical Schools, and, so far as can be at present judged, the number of students will be fully up to, if not beyond, the average of the past few years. Reviving what used formerly to be an annual custom in connexion with the opening of the winter session in the University, the Principal, Sir Alexander Grant, delivered an address to the students. Referring to the recent Tercentenary festival, he said that the lesson of the celebration should remind students and office-bearers alike of their responsibilities, and stimulate them to maintain and carry on the

Digitized by Google

work of their predecessors. He referred with great satisfaction to the part which the students had taken in the festival, and congratulated them on the step which had been taken towards the organisation of student life by the establishment of the Students' Representative Council. "What I want," he said, "to bring out and emphasise is that the general body of students of this University appeared at the festival and on other occasions during the year no longer as a fortuitous concurrence of atoms, but in some respects as an organic body, self-organised; no longer inarticulate, but provided with the means of constitutionally expressing its ideas and wants, and exhibiting considerable *savoir faire*." He next alluded in some detail to the Bill which had last session been introduced for the Better Endowment and Improvement of the Scotch Universities. Ultimately, he said, this or a similar Bill will become law, and it will afford scope for improvement in the University, and its results will stamp the character of our fourth centenary. The Universities (Scotland) Bill of last session was, taken all in all, a very good Bill, but not a perfect Bill—and for this reason, that it was not, so to speak, a holograph; it was not of one authorship, but a composite production, made up of separate contributions from distinct sources—namely, from the Lord Advocate's office and from Her Majesty's Treasury. And he compared these two threads in the Bill to the Rhone and the Arne, running together distinct in one bed—"a clear stream flowing by a muddy one." Almost all the provisions in the Bill devised by the Lord Advocate were admirable, but they were marred by clauses which came in from the Treasury. What he complained of was the principle which the Treasury attempted to introduce into the Bill. This principle was, that from henceforth University education is to be cut off from any additional State support; that, whatever may be the unforeseen developments of science, while other nations go on richly endowing its prosecution, not a penny more than a sum now fixed is to be voted for its encouragement in Scotland, and that the sum fixed for all University purposes in this country is to be about 1 per cent. of the present educational vote for the United Kingdom. He also considered it a serious *lapsus* in the Lord Advocate's measure that he consented to provide that no part of the additional grant from the State should be allowed to go to augment the endowment of any of the Theological chairs. Some of the problems which the Executive Commission appointed under this Bill would have to deal with were very complex and difficult, such for example as—1. How to rearrange the rules of graduation in arts and in science, so as to give a wide choice of subjects to the candidate, and to open a number of alternative avenues to a degree, and yet to preserve a perfect equality as to ease and difficulty of access, and prevent some subjects from being duly favoured and others doomed to comparative neglect. 2. How to adjust into perfect equity a fee fund, so that the interests of individual professors should no longer, as hitherto, be isolated, but should be more bound up in the corporate prosperity of the University. These were problems worthy of the strongest and wisest heads, but they could hardly be dealt with prudently unless there be in the Commission a strong infusion of actual knowledge and experience of the working of the Scottish Universities. After referring to the way in which university work was to be tested, Sir Alexander concluded by touching upon what might be the philosophical attitude of the University in the future; he saw no reason to expect that it would accept the mechanical cosmism of Darwinism in its extreme developments, or its clumsy and infelicitous attempts to evolve reason out of matter.

NEW LECTURE ROOMS AT SURGEONS' HALL.

A very great and much needed improvement has been effected at Surgeons' Hall. The dissecting-room has been enlarged to twice its former size, a bone-room has been added, while ample accommodation has been provided for the practical teaching of physiology and pathology. The chemical and other departments have also been much improved, and spacious staircases added. Dr. Macdonald Brown has succeeded Dr. Cathcart in the anatomical department of Surgeons' Hall. Dr. Cathcart has commenced to lecture on surgery at Nicholson-square.

MR. JOHN WINNALL GEORGE, M.R.C.S., public vaccinator for the Malvern and Leigh districts, Worcestershire, has received for the second time the Government grant for efficient vaccination.

IRELAND.

(From our own Correspondent.)

ROYAL UNIVERSITY OF IRELAND.

THE meeting of Convocation which was held last week fell through in consequence of a sufficient quorum not having been present. The circumstance is to be regretted, as Mr. Maguire's motion in reference to the statement that the examination papers of the University are known before to certain candidates was expected to be fully discussed. Dr. C. F. Knight also intended to move a resolution to the effect that the Senate should consider the advisability of holding the medical examinations in the months of May and November in each year, and should admit undergraduates of the University and of the late Queen's University in the faculty of medicine to two examinations in the year. The apathy and indifference shown by members of Convocation, particularly those resident in Dublin, are extremely to be regretted, and their absence at such an important meeting appears incomprehensible.

The Senate have arranged that the course for the examination for the Stewart Scholarship for proficiency in mental diseases shall include diseases of the brain and spinal cord, and diseases of the nervous system, practical examination of patients labouring under such diseases, and written reports of the same. Candidates will also be examined with the microscope on various pathological specimens and preparations illustrative of those diseases. The examination for the scholarship will occupy not less than three days.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

The College of Physicians in Ireland for a considerable time past has granted its diplomas to female candidates, and it is probable that before long the Royal College of Surgeons will follow in the steps of its sister corporation. The matter was recently brought before a committee of the Council, when, on the motion of Dr. Cameron, Vice-President of the College, seconded by Dr. Kidd, the proposal to admit women to the examinations of the College, should the Council think fit, was carried on a division by nine to four. It is expected that steps will shortly be taken to have an alteration made in the Charters of the College, so that voting for Council by means of balloting papers sent by post as well as by personal attendance may come into operation.

ACADEMY OF MEDICINE IN IRELAND.

The second annual general meeting will take place this week, when the reports from the General Council and the general treasurer will be submitted, and the election of office-bearers take place. Among the notices of motion to be considered at the meeting are two of importance—viz., one by Mr. Swanzy, and the other by Dr. Duffey. Mr. Swanzy suggests that it be referred to the General Council to consider whether it be desirable that the Academy should encourage original research by grants or otherwise, and Dr. Duffey will move that no officer of the Academy shall receive any emolument from its funds. As far as finance is concerned, the Academy is flourishing, commencing, as it does, its second session with a balance in hand of £305.

PROPOSED HOSPITAL FOR CONSUMPTION, BELFAST.

Last week Mr. Forster Green, a well-known citizen of Belfast, handed to the chairman of the managing committee of the Belfast Royal Hospital a cheque for £5000, the interest of which is intended to be used for the treatment of patients suffering from consumption in a portion of the Convalescent Home on the Throne Lands. It is satisfactory to find that this sum has been supplemented by donations for the same purpose from several others, so that up to the present £887 8s. 1d. has been obtained in addition to the munificent subscription of Mr. Green.

Professor Rawdon Macnamara will deliver the inaugural address at the Meath Hospital on Monday next, Nov. 3rd.

Dr. Edmund Coates of Portumna was accidentally killed by a fall from his horse on Oct. 18th at the early age of thirty-six.

Dr. Nunan has been elected, for the sixth time in succession, chairman of the Kinsale Town Commissioners for the ensuing year.

Dr. Auterson of Magherafelt has been appointed to the Commission of the Peace for the county of Londonderry.

Dublin, Oct. 28th.

PARIS.

(From our own Correspondent.)

CHOLERA AT YPORT.

YOU will have heard of the outbreak of cholera on the 23rd Oct. at Yport, a small fishing village on the coast of Normandy, between Etretat and Tréport, the origin of which was clearly traced to the importation of the germs of the disease under the following circumstances:—On September 25th some of the crew of a French fishing boat that had come from Newfoundland, and was anchored at Cette, one of the cholera-stricken towns in the south of France, arrived at Fécamp, a small seaport town in Normandy, not far from those above-named. These men travelled by rail from Cette, and on their arrival at Fécamp, which is near to their home, they had to take a sulphur bath, and fresh clothes were issued to them before they were allowed to go any further. Unfortunately, however, their own clothes, which were supposed to have been thoroughly disinfected (having gone through the form), were given back to them. On October 4th some of the disinfected clothes were washed in the sea by a female peasant, who fell suddenly ill, and died in a few hours; the physician who attended her at once recognised the malady as being Asiatic cholera. The victim was sister-in-law to one of the sailors, who was not affected by the disease, nor, indeed, were any of the others who accompanied him from Cette. The disease spread rapidly, and in the next day or two ten persons were attacked, of whom seven died, and the other three recovered. Measures were immediately taken to prevent the spread of the disease. Six more cases, however, subsequently occurred, making in all sixteen up to yesterday, of which there were nine deaths, three cured, and four under treatment. Dr. Gibert, sanitary medical officer at Havre, who was ordered to proceed to Yport and report on the character of the epidemic, concurred with the local medical men as to the malady being Asiatic cholera; but, thanks to the energetic measures that have been taken to ensure salubrity in the dwellings and in the streets, which were in a deplorably filthy condition, the epidemic has been brought under, and appears to have no tendency to spread. Dr. Gibert, moreover, observed that the persons affected were nearly all given to intemperance. Dr. Proust, principal sanitary officer of Paris, was also sent to Yport, but his report has not yet been published.

HORSE-POX.

Dr. Blachez brought to the notice of the Academy of Medicine last week an epidemic of horse-pox which lately took place at the Hospice des Enfants-Assistés. The malady was first observed in the nursery into which none but syphilitic infants, or those suspected to be such, are received. One of the infants had an ulcer on the lower lip with enlargement of the neighbouring glands, and the ass that suckled it had a deep excoriation on the teat which was noticed two days before the ulcer in the child. The animal so infected had for fifteen days suckled another infant that had an ulcer on the tongue, which naturally gave rise to suspicions of syphilis. The epidemic went on extending, when MM. Fournier and Bouley were consulted as to the nature of the prevalent malady. M. Fournier was doubtful as to its nature, but M. Bouley, the well-known veterinarian, at once pronounced it to be horse-pox, the origin of which had to be sought for. It was noticed that another infant, who had been admitted twelve days previously, had both its arms covered with vaccine pustules which were dressed by the "infirmier," who, having his fingers thus affected, inoculated the teats of the suckling asses. Other asses were also similarly affected, which was sufficient to account for the origin of this strange epidemic among the infants.

Paris, Oct. 29th.

THE SERVICES.

Deputy Surgeon General Herbert Taylor Reade, of the Medical Staff (late Army Medical Department), who was commended in despatches for his services in the Indian Mutiny Campaign, has been appointed on the Staff of Major-General R. White, commanding the Eastern District, as Principal Medical Officer, vice Surgeon-General T. Murphy, retired.

WAR OFFICE.—Medical Staff: Surgeon-Major William Edmondson Dudley is granted retired pay, with the honorary rank of Brigade-Surgeon; Surgeon-Major Humphrey Carden Gillespie, M.D., is granted retired pay, with the honorary rank of Brigade Surgeon.

MILITIA MEDICAL DEPARTMENT.—Surgeon-Major Wavll Arundel Dene, 3rd Battalion, the Prince Albert's (Somersetshire Light Infantry), resigns his commission; also is permitted to retain his rank and to wear the prescribed uniform on his retirement.

ADMIRALTY.—The following appointments have been made:—Fleet Surgeon William Connolly, M.D., to the *Duke of Wellington;* Fleet Surgeon Gerald Molloy, to the *Dædalus;* Fleet Surgeon Edward J. Butler, B.A., M.D., to Malta Dockyard; Fleet Surgeon Mark A. Harte, to the *Achilles;* Surgeon G. A. Dreaper, Surgeon William H. O'Meara, Surgeon William W. Jacobs, Surgeon Alexander F. Harper, Surgeon Herbert W. A. Burke, Surgeon Edward R. D. Fasken, Surgeon James C. F. Whicher, Surgeon Alexander G. Andrews, Surgeon Arthur S. Nance, and Surgeon Evan St. M. Nepean to the *Duke of Wellington,* additional; Surgeon John S. Lambert, to the *Hibernia;* Surgeon Frederick J. Lilly, to the *Northumberland;* Surgeon Edward J. Morley, to the *Excellent;* Surgeon Joseph R. M'Donnelly, to the *Hercules;* Surgeon George L. Baker, to the *Lark;* Surgeon Henry Canton, to the *Royal Adelaide;* Surgeon Thomas C. Rowland, to the *Undine.*

Obituary.

MR. THOMAS CHAVASSE, F.R.C.S.

WE announced last week the decease, on the 19th ult., of Mr. Thomas Chavasse, one of the few remaining members of a school nearly extinct. Originally of French extraction, Mr. Chavasse was descended from a race of surgeons that had practised at Burford, in Oxfordshire, for many generations. His father, being qualified to practise before there was a vacancy in the family practice, settled at Walsall, where the deceased was born in May, 1800. His early education was received at the Kensington Gravelpits School, and at the age of sixteen he was apprenticed as resident pupil for five years to the General Hospital, Birmingham. At the expiration of his term of apprenticeship he became a student of St. Bartholomew's Hospital, and was a diligent follower of Mr. Abernethy, whose work and teaching made an impression on his after-life that was never effaced. Having obtained the Membership of the College of Surgeons and the Licence of the Apothecaries' Society, Mr. Chavasse returned to Birmingham in 1822, and in a few years acquired what is generally believed to have been the largest general practice ever attained in the provinces. At this he worked incessantly until 1850, when, his health failing, he retired to Leamington. In 1844 he received the Honorary Fellowship of the College of Surgeons. A rest of three years having sufficed for restoration to health, Mr. Chavasse settled at Wylde-green, and recommenced professional practice. At the same time two days in the week were devoted to consultation work in Birmingham. This course was actively followed until he had reached his eightieth year, when the infirmities of age first really became marked.

For many years Mr. Chavasse was a member of the Sutton Coldfield Corporation, and for three successive years he was warden or mayor of that Royal town. At the expiration of the term of office he was appointed "capital burgess;" but, magisterial work being distasteful to him, after occupying the position for some time, he resigned his seat on the bench. Until the last few years he also acted as one of the trustees of the Medical Benevolent Society, and ever showed great personal interest in the work of that Society. He was amongst the first who enrolled themselves as members of the Provincial Medical and Surgical Association, his name appearing in the list in the first volume of the Transactions of the Society. To the fourth volume of the Transactions he contributed a paper on "Secale Cornutum," and to our own pages one on "Uterine Hæmorrhage: the Injection of Cold Water as a Remedy."

ROYAL COLLEGE OF PHYSICIANS.

THE ordinary Comitia of the Royal College of Physicians was held on Thursday last, Oct. 30th, Sir W. Jenner, Bart., President, in the chair. A considerable amount of routine business was transacted. The President nominated Dr. R. Quain to be Harveian Orator for next year, and Dr. Mahomed as Bradshawe Lecturer.

Dr. Mahomed moved, and Dr. F. T. Roberts seconded, the following resolution :—"That a Committee be appointed to consider whether any means might be advantageously adopted byt he Government or other public body, to ascertain and certify the composition and quality of patent and manufactured medicines, of unofficinal and also officinal drugs, and of all drugs dispensed under the prescriptions of registered medical practitioners. That the Committee report to the College at an early date."

The resolution was opposed by Dr. Bristowe and Dr. W. Farre, and negatived.

MEDICAL NOTES IN PARLIAMENT.

Over-pressure in Schools.

IN the House of Commons on Tuesday, in reply to a question by Mr. S. Leighton, of which notice had been given on the previous evening, Mr. Mundella stated that immediately on receipt of Dr. Crichton Browne's report it was sent to Mr. Fitch, who, after perusal, expressed dissent from and dissatisfaction with the document. Previously to Dr. Crichton Browne's report being made public, Mr. Fitch was not requested to make any official report. In reply to a further question, Mr. Mundella stated that Mr. Fitch was a member of the committee which was employed in drafting the New Code.

The Outbreak of Cholera in Normandy.

In reply to a question by Sir W. Barttelot, Sir C. Dilke stated that information respecting the nature of the outbreak at Yport had been asked for and partially obtained. A most complete examination of ports has been made in advance for four months with a view to prevent cholera spreading to this country, and all regulations in force during the last epidemic to check the importation of disease are in force at the present time.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON. — The following gentlemen passed the Second Examination in Anatomy and Physiology on Oct. 23rd :—

Betts, Robert Sidney.
Daly, Stephen Joseph.
Green, Alfred.
Hewan, John.
Lewis, Benjamin Morgan.
Norris, Herbert Murray.
Phipps, Henry Hostache.
Smith, Newman.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having passed the required examination for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on Oct. 23rd :—

Bell, Charles W. Josceline, L.R.C.P.Ed., Dulwich Wood Park.
Bell, George Craigie, Blackheath.
Bury, Herbert Taylor, Hampstead.
Byrne, George, L.R.C.P.L., Manchester.
Clayton, Geoffrey Sherborne, L.S.A., Hampstead.
Fisher, Henry Oldrich, Sittingbourne.
Hewish, Edgar Milne, M.D.Toronto, Toronto.
Hillstead, Herbert John, L.S.A., St. John's.
Jacomb-Hood, Charles John, L.S.A., Tunbridge Wells.
Jessop, Edward, Nottingham.
Kerby, Robert John, L.R.C.P.L., Crouch Hill.
Lloyd, Henry, L.S.A., Denbigh.
Noad, Ernest, L.R.C.P.Ed., Christ's Hospital.
Penfold, Frederick William H., Rainham.
Shaw, Hugh Grosvenor, L.R.C.P.Ed., Stratford-on-Avon.
Weakley, Alfred James, L.R.C.P.L., Leytonstone.

Admitted Members of the College on Oct. 24th :—

Averill, Charles, L.S.A., Stafford.
Best, William James, L.S.A., Queensdown-road.
Blair, Charles Samuel, M.B Durh., Newcastle-on-Tyne.
Cusse, Ernest, L.S.A., Great Ormond-street.
Cann, Ralph Thomas, L.R.C.P.Lond., Lambeth-palace-road.
Carr, John Walter, L.S.A., Bloomsbury-square.
Gubb, Alfred Samuel, L.S.A., Southampton.
Santi, Philip Robert W., L.S.A., Doughty-street.
Tuck, Harry, L.S.A., Surbiton.
Tytheridge, Walter Robert, L.R.C.P.Ed., St. James's-square.
Williams, Reginald Muzio, L.S.A., Beaumaris.

Thirty-two candidates passed the examination in Surgery, and will be admitted Members of the College on obtaining a Medical diploma.

The following gentlemen, having passed the necessary examination, were admitted Licentiates in Dental Surgery and received their diploma at a meeting of the Board of Examiners in that subject on Oct. 29th :—

Ackland, W. Robert, Southernhay, Exeter.
Crocker, James Charles Vipond, Penzance.
Levason, Peyton Grenville, Bridge-street, Hereford.
Parkinson, Herbert Stephen, Sackville-street.
Roberts, Charles Alfred, Weymouth-street.

Three candidates were referred.

UNIVERSITY OF CAMBRIDGE.—At a congregation held on October 24th the following degrees were conferred :—

BACHELOR OF MEDICINE.—Robert Whinery Leeming, Christ's; Arthur William Chalmers Peskett, Downing.
BACHELOR OF SURGERY.—Arthur W. Chalmers Peskett, Downing.

On the same day the following were appointed Examiners :—First Examination for M.B. Degree : Professor A. Schuster, Owens College, Manchester; Mr. W. N. Shaw, Emmanuel; Mr. A. Scott, Trinity; Mr. M. M. Pattison Muir, Gonville and Caius; Mr. F. Darwin, Trinity; Mr. H. M. Ward, Christ's; Dr. A. M. Marshall, St. John's; Mr. A. Sedgwick, Trinity. Second Examination for M.B. Degree : Professor Macalister; Mr. Alexander Hill, Downing; Professor Michael Foster; Mr. J. N. Langley, Trinity; Professor Latham.

ROYAL UNIVERSITY OF IRELAND. — The following degrees were conferred last week by his Grace the Duke of Abercorn, Chancellor of the University :—

BACHELOR IN MEDICINE.—Honours : First Class—R. J. Macnamara. Second Class—William White, John Kearney, Thomas Grainger, Joseph Daly, James Morwood,—Upper Pass Division : W. Battley, Robert Carter, Maurice Connery, Charles Cooke, Charles Elliott, Thomas Frizell, Benjamin Hosford, Philip Macarthy, Dennis Sheahan.—Lower Pass Division : William Bailey, Patrick Blackhall, Arthur Blackwood, Frederic Burns, George Clarke, John Corbett, Patrick Cotter, Warren Crooke, James Ferguson, Joseph Guisani, Charles Graves, Edward Greene, Charles Hayden, Peter Horkan, Samuel Hunter, Hugh Lewers, Marcus London, James McEvoy, Nicholas McDonnell, Joseph McKay, Morgan McSwiney, Edward Magennis, James Magner Donald Martin, John Moore, Hugh Morrison, Cornelius O'Doherty, Michael O'Halloran, Patrick O'Hara, J. Prendergast, Frederic Sinclair, Alfred J. Smith, Patrick Soraghan, Alfred Starling, George Tate, Wm. Wadsworth, George Waters, George Nesbitt Wynne.

MASTER OF SURGERY.—William Bailey, W. Bartley, P. Blackhall, Arthur Blackwood, Robert Carter, George Clarke, Maurice Connery, Charles Cooke, John Corbett, Patrick Cotter, Warren Crooke, Joseph Daly, Charles Elliott, Jacob Fairbrother, James Ferguson, Thomas Frizell, Joseph Guisani, Thomas Grainger, Charles Graves, Edward Greene, Charles Hayden, Peter Horkan, Benjamin Hosford, James Hunter, Samuel R. Hunter, John Kearney, John Keany, Hugh Lewers, Marcus London, James Macaulay, Matthew McAuley, James McAvoy, Philip McCarthy, Nicholas McDonnell, Joseph B. McKay, Robert Macnamara, William McWilliam, James F. Magner, W. Martin, James Morwood, James O'Connell, Cornelius O'Dogherty, Michael O'Halloran, Patrick O'Hara, Denis Sheahan, Alfred Smith, P. Soraghan, Alfred Starling, George Tate, George Waters, William White, George N. Wynne.

DIPLOMA IN OBSTETRICS.—Patrick Blackall, Arthur Blackwood, J. W. Bullen, Patrick Cotter, Charles Elliott, James C. Ferguson, Joseph Guisani, Thomas Grainger, Samuel Hamilton, Benjamin Hosford, John Kearney, Hugh Lewers, James McAvoy, Philip McCarthy, Nicholas McDonnell, James Magner, James Morwood, Cornelius O'Dogherty, Michael O'Halloran, Denis Sheahan, Alfred J. Smith, Alfred Starling, William White.

DIPLOMA IN SANITARY SCIENCE.—John Roche.

EXHIBITIONS.—First Class (£50): Robert J. Macnamara. Second Class (£25 each): *William White, John Kearney, Thomas Grainger, Joseph T. Daly.

*Disqualified by University or Collegiate standing.

APOTHECARIES' HALL. — The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Oct. 23rd :—

Best, W. Jas., Richmond House, Queenstown-road, Clapton.
Jones, J. Arnallt, Abergwesyn Vicarage, Llanwrtyd, Brecon.
Lloyd, Henry, Llahrhaiadr, Denbigh
M'Donnell, Alexander, Kingsland-road.
Tronson, W. Francis, Oxford-gardens.
Williams, Reginald Muzio, Tre Castell, Beaumaris, Anglesea.

The following medals have been awarded by the Society of Apothecaries during the past year :—Materia Medica and Therapeutical Chemistry : Gold medal, John Henry Garrett, University College; silver medal and books, Henry Hamilton, Bristol Medical School. Botany : Gold medal, Ernest H. Starling, Guy's Hospital; silver medal and books, William Beecroft Bottomley, St. Mary's Hospital. A gold medal has also been awarded to Bertha Whitehead, and a silver medal

Digitized by Google

to Sarah Elizabeth Wright.——The Society's gardens at Chelsea have been visited during the year by 3248 students, three-fifths of whom were males.

THERE appears to be a paucity of subjects for anatomical purposes in Edinburgh.

THE late Countess Bose of Cassel has bequeathed to the University of Berlin the sum of 780,000 marks (£39,000) for the benefit of poor students of medicine.

A SAILING-VESSEL, the "F. I. Merryman," has arrived in New York, the whole of the crew with the exception of two having been removed by fever during the voyage from Bathurst on the west coast of Africa.

THE offices of Medical Officer of Health and that of Public Analyst in St. Luke's parish, which have heretofore been held conjointly by Dr. Pavy, have, on his resignation, been made separate appointments.

VACCINATION PROSECUTIONS.—It appears that out of 1595 convictions for neglecting to comply with the Vaccination Act for the year ending Sept. 29th, 1883, no fewer than 422 took place in the town of Leicester. In the West Riding of York there were 140 convictions; in Halifax, 104; in Oldham 91; in Lincoln, 87; and in Derby and Nottingham, 58 each. During the year fines were imposed in 1190 cases.

THE METROPOLITAN ASYLUMS BOARD.—At the meeting of the managers of the Metropolitan Asylums Board on the 25th ult., it was announced that the Local Government Board had authorised the expenditure of £2425 in connexion with the hospital-ship *Castalia*, and the borrowing of £1630 of this amount. Relative to the question of the removal of non-pauper cases of infectious disease to the managers' hospitals, a recommendation made by the General Purposes Committee was adopted, to the effect that the Local Government Board be requested to place themselves in communication with the several local authorities of the metropolis, with the view to issuing an order which shall empower the managers (in accordance with the terms of Clause 15 of the Poor Law Act of 1879) to contract with such authorities for the reception into the managers' hospitals of cases of dangerous infectious disorders other than those chargeable to the various parishes and unions.

BOOKS ETC. RECEIVED.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

ADDENBROOKE, E. H., M.R.C.S., L.S.A.Lond., has been appointed Certifying Surgeon, under the Factory Act, for the District of Kidderminster, vice Wm. Roden, M.D., deceased.

ARMITAGE, E. H., M.R.C.S., L.R.C.P.Lond., has been appointed Resident Medical Officer to the Hulme Dispensary, vice J. B. Dreaper, M.R.C.S., resigned.

BARBOUR, J. M., M.B., has been elected Honorary Surgeon to the Royal Alfred Sailors' Home, Bombay, vice Cassum, deceased.

BURRY, HENRY B. PULLEN, L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer for the Milland District of the Midhurst Union, vice Pearse, whose term of office has expired.

BUSH, JAMES PAUL, M.R.C.S., L.S.A.Lond., has been appointed Surgeon to the Bristol Police Force, vice Cross, resigned.

CHAMBERS, H. W., L.R.C.P., M.R.C.S., has been appointed Senior Assistant House-Surgeon to the Hull General Infirmary, vice Jackson, resigned.

DAVIES, J. T., L.R.C.P.Ed., M.R.C.S., has been appointed House-Surgeon to the Denbighshire Infirmary, vice Lloyd, resigned.

DREAPER, J. B., M.R.C.S., has been appointed Honorary Surgeon to the Hulme Dispensary, vice A. J. Neale, M.B., C.M.Ed., resigned.

ELPHINSTONE, ROBERT, L.R.C.P.Lond., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Silverstone District of the Towcester Union, vice Weir, deceased.

FULLER, ARTHUR, M.B., C.M.Ed., M.R.C.S., has been appointed Assistant Medical Officer to the Hackney Union Infirmary, vice Dr. Gordon, promoted.

HARRIS, THOS., M.D.Lond., M.R.C.S., has been appointed House-Physician to the Radcliffe Infirmary, Oxford.

HARVEY, WILLIAM, L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer to the Maytown Hospital, Queensland.

HOZIER, C. H. SMITH, F.R.C.S., L.K.Q.C.P.I., has been appointed Government Medical Officer and Vaccinator for the District of Gundagai, New South Wales; also Surgeon to the Hospital.

PASH, WILSON, M.A. & M.B.Cantab., of Laurie-park, Sydenham, has been appointed House-Physician to the London Hospital.

THOMSON, JOHN, M.D., Ch.M.Aber., has been appointed Government Medical Officer and Public Vaccinator for the District of Silverton, New South Wales.

WADE, CHARLES, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Hatfield District of the Dunmow Union, vice Firman, resigned.

WILSON, G. J., M.R.C.S., L.S.A.Lond., has been appointed House-Surgeon to the Radcliffe Infirmary, Oxford.

WILSON, JAMES SCOTT, M.B., C.M.Glas., has been appointed Medical Officer for the Borough District of the Walsall Union, vice Hubbard, resigned.

Births, Marriages, and Deaths.

BIRTHS.

BARLOW.—On the 23rd ult., at Montague-street, Russell-square, the wife of Thomas Barlow, M.D., F.R.C.P., of a son.

BURRY.—On the 18th ult., at Liphook, Hants, the wife of H. B. Pullen Burry, L.R.C.P., M.R.C.S., &c., of a son.

CARR.—On the 20th ult., at Long-street, Devizes, Wilts, the wife of Alfred Carr, M.R.C.S., of a son.

FENNELL.—On the 24th ult., at Knutsford, Cheshire, the wife of Theodore Fennell, M.R.C.S.E., L.S.A.Lond., of a daughter.

LANCASTER.—On the 21st ult., at Neston Lodge, Lewisham High-road, S.E., the wife of Henry F. Lancaster, M.D., of a son.

WISE.—On the 23rd ult., at Walthamstow, the wife of C. H. Wise, M.D., of a daughter.

MARRIAGES.

ATKINS—HUNT.—On the 25th ult., at Kilrosanty Church, Ringrose Atkins, M.A., M.D., Resident Medical Superintendent, District Lunatic Asylum, Waterford, to Mary Ellen, second daughter of the late Thomas Hunt, Esq., of Rockmount, co. Waterford.

HODGES—VIDLER.—On the 22nd ult., at St. Nicholas' Church, Remenham, James Hodges, M.R.C.S., L.S.A.Lond., of Bury St. Edmunds, eldest son of the late Rev. James Hodges, of Shippon, Berks, and of St. Helier's, Jersey, to Alice Maria, youngest daughter of William Vidler, of Remenham, Berks.

HUMPHREYS—HARRATT.—On the 22nd ult., at the Parish Church, Wallington, Surrey, John Henry Humphreys, M.D.Lond., youngest son of the late Charles Humphreys, Esq., of Oswestry, Salop, to Helena Joaquina, eldest daughter of the late Charles Harratt, Esq., of Liverpool and Buenos Ayres.

DEATHS.

BROWN.—On the 22nd ult., after a short illness, Charles Blakely Brown, M.D.Oxon., of Hill-street, Berkeley-square, W.

GIBSON.—On the 19th ult., at Prospect-street, Hull, Henry Gibson, M.R.C.S., aged 71.

LUKE.—On the 22nd ult., at the residence of his sister, Beulah-villas, Clive-vale, Hastings, Joseph Luke, M.D., of Oak Lodge, Green-lanes, Finsbury-park, N., aged 66.

SHEEHY.—On the 24th ult., at his residence, Great Percy-street, W.C., William Henry Sheehy, L.R.C.P.Edin., late of Claremont-square, in his 65th year.

ST. CLAIR.—On the 21st ult., at Cain House, Wigtown, Scotland (formerly of Blackpool), James Aitken St. Clair, B.M., C.M., in his 38th year.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, November 3.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10½ A.M. each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.

ST. MARK'S HOSPITAL.—Operations, 2 P.M., and on Tuesdays at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

ROYAL INSTITUTION.—5 P.M. General Monthly Meeting.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—8 P.M. Casual Communications by Messrs. Ackery, A. S. Underwood, Storer Bennett, and Morton Smale.—Mr. F. Newland Pedley: Some Points in connection with Fracture of the Lower Maxilla.

MEDICAL SOCIETY OF LONDON.—8.30 P.M. General meeting.—Mr. Edmund Owen: Lancing the Gums.—Dr. de Havilland Hall: A Case of Surgical Scarlet Fever.

Tuesday, November 4.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 P.M., and Thursdays at 2 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Hale White: Coarctation of the Aorta.—Drs. Hobson and Lanchester: Caseous Pneumonia simulating Empyema.—Mr. Barker: Removal of Upper Jaw for Epithelioma.—Dr. Percy Kidd: Cardiac Aneurysms.—Dr. Howard Tooth: Lympho-sarcoma of the Liver in a Child.—Dr. Carrington: Cancer of the Liver and Adrenals, with Melanæmia, &c.—Dr. Acland: Two Cases of Ulceration of the Intestines in Paraplegia.

Wednesday, November 5.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.—Ophthalmic Operations on Tuesdays and Thursdays, at 1.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1½ P.M.—Skin Department: 9.30 A.M., on Tuesdays and Fridays.

ST. THOMAS'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.

LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations 2½ P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour.—Skin Department: 1.45 P.M., and on Saturday at 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

MEDICO-PSYCHOLOGICAL ASSOCIATION.—3.30 P.M. Council Meeting.—4 P.M. Dr. A. H. Newth: The Value of Electricity in the Treatment of Insanity.

OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by Mr. Lawson Tait and others.—Dr. Grailly Hewitt: The Severe, or so-called "Uncontrollable," Vomiting of Pregnancy.—Dr. Potter: Retained product of Conception.

Thursday, November 6.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—1½ P.M. Surgical Consultations.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.

NORTH-WEST LONDON HOSPITAL.—Operations, 2½ P.M.

HARVEIAN SOCIETY.—8.30 P.M. Dr. Stephen Mackenzie: Two Cases of Lichen Planus of Nervous Distribution.—Mr. J. H. Morgan: Cases of Painful Mamma in Young Girls.—Dr. Amand Routh: Cases of Retroversion of the Gravid Uterus.—Mr. R. F. Benham will exhibit a New Antiseptic Vaporiser and Improvements in Syringes.

Friday, November 7.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1½ P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 2 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—8 P.M. Mr. Bernard Pitts: Foreign Body in the Air-passage; Abscess of the Lung; recovery.—Mr. Maitland Thompson: Case of Retention (twenty-four hours); Catheter Fever; death.—Mr. Noble Smith: The Objects of the Medical Sickness Annuity and Life Assurance Society.—Dr. Chas. Good: Gastric Ulcer Rupture; sudden death.

Saturday, November 8.

KING'S COLLEGE HOSPITAL.—Operations, 1 P.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

IN MEMORIAM.—SAMUEL RABBETH.

Sad is each heart, and dimmed with tears each sight.
A nother from our midst has passed away,
M anhood scarce reached! And yet before him lay
U nrolled a future, glorious and bright.
E ver his duty to perform aright
L ived he and died. What more of man to say?

R ead, all, a lesson in his life now past;
A nd in his death read we no lesson too?
B right as our sky of life is now to view,
B lack with death's clouds soon it may be o'ercast.
E ach day we live may be, like his, the last.
T hen let this thought be ever with each one:
H ere for to-day—perchance to-morrow gone.

King's College Hospital, Oct. 29th, 1884.

Enquirer.—The certificate testifies to the efficiency of the holder to compound and dispense medicines.

Mr. Nixon.—A short notice of the portable hospital was given in our last issue.

DISINFECTION.

To the Editor of THE LANCET.

SIR,—Will you kindly give me, through the medium of THE LANCET, the benefit of your opinion on the following question of practical disinfection? Is it safe, after thorough fumigation by sulphur, to allow the paperhangings to remain on the walls of bedrooms which have been occupied by cases of (1) measles and (2) enteric fever? I require its removal after cases of small-pox, scarlet fever, and diphtheria, and have generally found no difficulty in getting it done; but there is a decided opposition, even among the "better classes," to removing it after measles and enteric fever, on the ground that it is not necessary, and this idea is often shared by the medical attendant. As medical officer of health for a popupar health-resort, I should feel obliged by the support of your opinion. I am, Sir, yours faithfully,

Oct. 15th, 1884. M. O. H.

*** Much depends on the efficacy of the fumigation. Assuming this to to be efficient, it is a good rule to suggest removal of wall-paper and white-liming of ceilings in all cases of infectious fever; but as regards enteric fever, it would be difficult to bring forward proof of its necessity. It is rather the mystery that attaches to certain recurrences of typhoid fever that makes it desirable to recommend it. The recommendation once made, it would probably be unwise to attempt to enforce it. In the case of measles, the need for stripping the walls is much greater; but the poison of measles, although very intense while it lasts, is probably one of the easiest to get rid of by proper disinfection, cleansing, and ventilation of apartments; and the after-history of attacks shows that success has attended these measures alone. The process of stripping, &c., should, however, always be recommended, and the responsibility of refusal should be thrown upon those who neglect the advice, or who advise to the contrary.—ED. L.

Subscriber.—1. Yes, so long as it does not interfere with the efficient discharge of their duties.—2. We cannot think that the practice of which our correspondent complains prevails to any extent.

Mr. J. Poland.—Yes.

QUERY.

To the Editor of THE LANCET.

SIR,—In proceeding to the Gold Coast as colonial surgeon for three years or longer, could any of your readers give me an idea of the nature, material, and amount of outfit I shall require, and what books of reference would be a *sine qua non*. I should value also some hints as to the climate, customs, &c. I am, Sir, yours truly,

Oct. 22nd, 1884. M.D.

THE VALUE OF SEWAGE.

AN intelligent correspondent has misunderstood our recent remarks in regard to the value of town sewage, and it is therefore probable that others have done the same. It is well known that at the present time it is impossible to make any profit, or, indeed, to avoid a great loss, in the disposal of town sewage under the water-carriage system. The ammonia of the sewage is by far the most valuable of its constituents, and would be worth millions a year if it could be recovered. But no method for this recovery is known, and the other constituents of sewage are so much diluted with water at all times, and so enormously diluted during wet weather, that sewage must remain, for the present, a source of loss, instead of gain, to the community. But none the less is it the duty of every country and of every age to save as much as possible of the constituents of food from the all-devouring sea. Now, every precipitation process for the disposal of sewage preserves for ultimate food supply some portion, at any rate, of the phosphates so essential to animal life, and so sparingly distributed on the earth's crust. Fishes, indeed, restore to the earth some portion of the phosphates wrenched from it by the sea; but there is a miserable disproportion between the gains and the losses. As regards phosphates, the balance of trade, so to speak, is entirely against the earth.

EMIGRATION OF LEUCOCYTES THROUGH THE WALLS OF CAPILLARIES.

To the Editor of THE LANCET.

SIR,—Though still only a student, I have regularly for some time read THE LANCET with great interest. Since reading the number for October 11th I have been much exercised in my mind by an article written by Mr. T. Wharton Jones. He there takes away from us students our old ground of belief in the extravasation of leucocytes in inflammation, and gives us nothing in its place. May I through your columns ask him in what way he explains the presence in an inflamed area of the very numerous cells which in all essential particulars exactly resemble leucocytes? In Ziegler's Pathology I am constantly meeting with such phrases as "the infiltrated area" (referring to inflammation), "the extravasated cells," &c. In what way are we to translate such sentences in the face of Mr. Jones's "Remonstrance?"

I am, Sir, yours truly,

London Hospital, Oct. 29th, 1884. F. J. SMITH, B.A.

*** We forwarded a copy of the above letter to Mr. Wharton Jones and have received from that gentleman the following reply:—

I am pleased beyond measure with Mr. F. J. Smith's inquiry, and fully sympathise with him in his perplexity. Mr. Smith's communication suggests to me that besides my remonstrance to authors, professors, and occasional orators against teaching that white blood-corpuscles escape from small vessels by boring through their walls without leaving any breach, I ought to have addressed one also to students, not to believe what their manuals and professors tell them on the subject until they have had demonstrated to them as a fact in nature what is merely asserted. Mr. Smith will remember that I am myself an inquirer merely, as well as an investigator; but in my experimental researches I have always been careful to suspend my belief in such matters until I could observe the facts; for seeing is believing. There are leucocytes and leucocytes; but, though resembling each other in external appearance, it does not follow that they have all emigrated from the blood. Surely, it could not be said that a crowd of people in the street must have issued from the houses, unless we saw them in the act. The white cells in the mesentery of the frog, which I refer to in my article as having been shown to me as white blood-corpuscles which had escaped from capillaries and venous radicles, were not white blood-corpuscles at all, and could not have escaped from non-existent vessels. If Ziegler (Pathology) did not see the cells actually boring themselves out through the walls of vessels, he has no right to say that he did. Extravasated blood-cells are not cells which have bored through the walls of vessels without leaving any breach. As a fact in nature, I refer Mr. Smith to the passage in my essay in the Guy's Hospital Reports for October, 1850, p. 51, quoted in my article. Professor Virchow's proliferation of cells is a fact in nature if we admit, as I contend we should do, that a condition for proliferation is a supply of lymph exuded from the blood by osmose, there being congestion in or adjacent to the part where the proliferation takes place. I shall always be happy to answer the inquiries of any perplexed student so far as my impaired strength may enable me to do so. Might I, in conclusion, suggest to the students of the different medical schools in London and elsewhere to require being shown as a fact in nature what their professors assert merely. A single glance at a crucial fact will teach a student more than all the talk of a lecture or the meaningless statements in a compiled book. T. WHARTON JONES.

ARTIFICIAL ARMS.

To the Editor of THE LANCET.

SIR,—If "Enquirer" will communicate with me, I will be pleased to give him some useful information of the new "Beaufort" arms, which will, I am sure, prove useful to his patient. I can give him details of several similar cases in which they have been used with success.

I am, Sir, yours truly,

JAMES THOMPSON, M.D.

1, Matheson-road, West Kensington, Oct. 28th, 1884.

Digitized by Google

Dr. G. de C. Morris.—1. The view that cholera is merely an aggravated form of ague has a few supporters.—2. Neither the Privy Council nor the Local Government Board has adopted the pamphlet referred to.—3. The Local Government Board makes no recommendation as to treatment.

Mr. W. Guthwaite.—We are not aware that Fellows of the Royal College of Surgeons do enjoy any special privilege or immunity in the respect mentioned—not even in barbers' shops.

EXAMINATIONS FOR OFFICERS OF THE MEDICAL STAFF.

To the Editor of THE LANCET.

SIR,—I wish I could say the revised scheme for examining medical officers of the army is free from blots and errors; but a careful perusal of it will show many weak points, which, with your permission, and in the interests of those concerned, I shall proceed to point out, in the hope that steps may be taken to remedy the defects.

First, in the examination for surgeons it is laid down that the candidate will be required to answer on "Medicine and Pathology, including modes of prescribing and administering remedial measures, food, drink, &c." Now, surely this is hardly necessary. These officers possess double qualifications, and, moreover, passed into the service through a severe competitive examination. They must have passed at least five years in the army, and to suppose it necessary to examine them in such elementary subjects seems a mere waste of time and trouble.

The next, and probably one of the most important mistakes in the circular, is that which requires a surgeon to present a certificate of operative surgery from "a recognised teacher of surgery in any medical school at home or abroad in which operative surgery is taught," and this certificate must be taken out "during the period within which the examination must be taken"—i.e., between the fifth and tenth years of service. It will be observed that this rule is absolutely imperative. No relaxation whatever is hinted at. I would ask, How is a surgeon of, say, seven or eight years' service, who may now be ordered to the Cape, China, Malta, Gibraltar, West Indies, &c., where there are no medical schools, to comply with this regulation? Clearly, either the rule must be relaxed, or the surgeon will, through no fault of his, be deprived of his promotion.

The next point I would notice is, that while the possession of the Fellowship of a College of Surgeons or Physicians exempts a surgeon from the examination in medicine and surgery, the degree of M.D. of a university, or M.Ch., confers no such immunity; and this is the more remarkable as the latter degrees are only conferred after examination, while the Fellowship of the College of Physicians is given by election. Again, the possession of a degree or diploma in hygiene from a university exempts the surgeon from that portion of the examination; but if he obtains this diploma from the College of Physicians it is not recognised. These are blunders of the most obvious kind, and call for immediate rectification.

In the revised circular—what I may call the second edition—the final clause lays down that an officer promoted for distinguished professional service will not be called on to pass any further examination. The result of this will be that a surgeon of, say, eight or ten years' service, and who may be fortunate enough to be promoted for, say, cutting a bullet out of a general's leg, is at once declared qualified for promotion to the rank of Surgeon-General without any further test or examination. I think I have said enough to point out, without any desire whatever to cavil at the authorities, that this circular has indeed been "crude in conception," though, as it is the second edition, we cannot say it "has been promulgated in haste." There is an old saying to the effect that "the third time is the charm"; and I hope the united talent of Whitehall-yard may be able, with the assistance of these humble remarks, to produce a third edition that will, at all events, be practicable and free from errors.

I am, Sir, yours faithfully,

CENSOR.

*** We have omitted parts of "Censor's" letter, as they, for the most part, refer to points in the examinations which have been modified in the revised regulations.—ED. L.

Dr. J. H. Warren (Boston, Mass.).—We regret we are unable to assist our correspondent. We cannot extend our exchange list.

"TRUSS FOR OBLIQUE INGUINAL HERNIA."

To the Editor of THE LANCET.

SIR,—In answer to "General Practitioner," on the subject of the best form of truss for oblique inguinal hernia, he will, I think, find that one with a spring making the complete circuit of the pelvis is always the best. The shape of the head, or, rather, the prominence of the padding of the head, must vary with the case, simple cases merely requiring a flat head, while more severe ones require a more prominent one. The use of the understrap is to prevent the head slipping up from its position over the external abdominal ring; but if the spring is sloped sufficiently down along Poupart's ligament, there ought to be no need for an understrap, except perhaps in the case of very thin subjects. In a few cases a "long head," in which the padding is continuous into an understrap, is absolutely needed; but such cases are rare. If "General Practitioner" would wish any other information, I will with pleasure render it.

I am, Sir, yours faithfully,

Oct. 27th, 1884. HEATHER BIGG, L.R.C.P., L.R.C.S.

MEDICAL ETHICS.

A CORRESPONDENCE between Dr. Charles White of Snodlands and Dr. Pope of Town Malling has been referred to us by Dr. White for our opinion thereon. Dr. White had been called to an accident at Snodlands, the injured persons being patients of Dr. Pope. This was not very explicitly stated to Dr. White, who regarded them as visitors and continued his attendance. On hearing this Dr. Pope felt aggrieved, and wrote a letter. What a pity it is that medical men, when they think themselves ill-treated by a medical brother, should so often write! *Litera scripta manet.* The chances are ten to one that some expression will escape the best man who feels himself injured, which, uttered in conversation, would be comparatively harmless and soon forgotten, but which in writing stays, and revives, and stings, and has to be vindicated, and gathers force in every fresh letter. This is the case here. Dr. Pope had really a right to complain. Enough, we think, was said to Dr. White at first to have led him to at least suspect that the patients were patients of Dr. Pope; but we cannot approve the style of his letters to Dr. White.

Z.—The revised circular obviates some of the objections raised in our correspondent's letter; and we therefore do not think it necessary to publish it.

CLEARING TRACHEOTOMY TUBES.

To the Editor of THE LANCET.

SIR,—The lamentable death of Dr. Rabbeth, and other unfortunate occurrences still fresh in the public mind, suggest the query, Is there no means of obviating such disasters? and induce me to claim attention to a very simple contrivance for clearing the tracheotomy tube. The apparatus comprises (*a*) an ordinary kitchen bellows in good condition, and (*b*) a flexible rubber tube of three-eighths of an inch in diameter, and convenient length (say four feet), one end having a vulcanite nozzle which will accurately fit the silver tube, and with a lumen sufficient to permit the free escape of mucus, &c., and the other end having a contracted lip, so as to be air-tight when slipped over the bellows nozzle. The valve of the bellows can easily be fastened down, by screwing into it a small gimlet and tying the latter securely to the lower handle. Explanation of the *modus operandi* is needless.

I am, Sir, yours obediently,

Oct. 23th, 1884. W. L. MORGAN.

To the Editor of THE LANCET.

SIR,—Reading last week the account of the deplorable death of one of our profession, and referring to the cleansing of the cannula from the obstruction of clot or mucus during the operation of tracheotomy, suction being what is required, I suggest, instead of applying the lips, let us have a syringe, the point of metal, the cylinder of glass, that we may see what enters the moment obstruction takes place. Fix the syringe instantly to the end of the tube, either by screw or slot, pull up the piston in the usual way; a vacuum is formed, and the obstruction at once drawn into the cylinder of the syringe.

We have so many clever instrument-makers that I have no doubt the instrument could be made effectively; and I should be glad to correspond with anyone for the carrying out of so desirable an object. In the large hospitals, where, I am told, the operation is often done, one of the surgeons might easily take the matter up and test it.

I am, Sir, yours truly,

Oct. 27th, 1884. W. HUTCHISON.

Mr. Richard Kershaw will see, from a letter in our present number, that the subject is already being taken up by the profession.

Mr. A. Fuller.—No.

A CIRCULAR.

To the Editor of THE LANCET.

SIR,—May I call your attention to this circular; and will you oblige by telling me what is the "usual honorarium" (Dr. Belcher's own phrase) for recommending invalids to the charge of a medical man? Is this a generally recognised transaction? and, if so, why is such a circular sent to

Yours faithfully,

Oct. 28th, 1884. F.R.C.P.

"Belgrave House, Berkhampstead, Herts, Oct. 24th, 1884.

"Dear Sir,—May I ask the favour of your recommendation, should you know of an invalid or anyone requiring a temporary or permanent home in the house of a married medical man. I am in practice at the above address, one hour by rail from London; locality healthy and picturesque. I should esteem your introduction a kindness. Ladies, gentlemen, or children received. Terms moderate. The usual honorarium.—I am, dear Sir, yours faithfully, J. S. BELCHER, M.D."

*** We have received from correspondents several copies of the same circular, and await Dr. Belcher's explanation.—ED. L.

KYESTINE IN EXTRA-UTERINE PREGNANCY.

To the Editor of THE LANCET.

SIR,—I would be glad if any of your correspondents could inform me about any observations on the presence or absence of kyestine in extra-uterine pregnancy. Parry and other most careful observers omit all notice of the symptoms. Doubtful as may be its bearing on the diagnosis of ordinary pregnancy, it would surely be of some use here.

I am, Sir, yours truly,

King-street, Manchester, Oct. 21st, 1884. J. THORBURN.

T. G. L.—The Secretary of the Brussels Medical Graduates' Association, Dr. Pocock, The Limes, St. Mark's-road, North Kensington, will no doubt give the information.

M.R.C.S.—See THE LANCET of Feb. 16th, 1878, and Sept. 3rd and 17th, 1881, for information on nervous affections of the hand.

M.D.—Most unsafe.

SANITARY ARRANGEMENTS AT CAMBRIDGE.

To the Editor of THE LANCET.

SIR,—As an undergraduate of Cambridge living in lodgings I have suffered considerably both from defective drainage and overcrowding. The rooms I first occupied on coming up are situated in a long street at the station end of the town, the houses (chiefly one storeyed) being generally inhabited by two undergraduates. The closet is in a small back yard, and is about four feet square, without any water-supply whatever. It is built on to, and forms a part of, the back kitchen, where the cooking is chiefly done. By the side of the closet is the coal cellar, about the same size, and next the pantry, which is about three feet three inches square. The pantry has one tiny opening, covered with perforated zinc, immediately underneath which, in the yard, is an open drain, down which all sorts of liquid matter are poured. I presume the noxious gases from this drain and from the closet adjoining must affect the food, which frequently was most unpalatable. The house contains three bedrooms proper, and during part of the time I resided there seven people slept in it. The two undergraduates each occupied their own rooms; the father and two sons, aged about seventeen and thirteen, occupied the remaining bedroom, whilst the mother and her daughter, aged eighteen, slept in the room in which the family lived. Need I say that when the house was shut up at night, and six of the seven had gone to rest, the odour was at times almost unbearable. In the house from which I am now writing the watercloset has no water-supply. The apparatus has been broken for many months past, and as the landlord declines to spend any money at all on the house there does not seem much prospect of matters improving. My experience of sanitary arrangements at Cambridge is unfortunate, to say the least; but it is not, unhappily, a solitary one. The arrangements at most of the houses in the street already referred to are similar. Numbers of the undergraduates complain and suffer, but nothing is done. I dare not enter into the subject of the river; it is beyond me. Barnwell Pool must be seen and smelt in order to be properly appreciated.

I am, Sir, yours faithfully,

Union Society, Cambridge, Oct. 14th, 1884. AN UNDERGRADUATE.

An Inaugural Address
ON THE
REVIVAL OF OVARIOTOMY,
AND ITS
INFLUENCE ON MODERN SURGERY.

Delivered at the Midland Medical Society, Birmingham, November 5th, 1884,

BY SIR SPENCER WELLS, BART.,
LATE PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MR. PRESIDENT AND GENTLEMEN, MEMBERS OF THE MIDLAND MEDICAL SOCIETY,—Next to the satisfaction which attends the fulfilment of the first duty of our calling—the relief of suffering and the prolongation of human life, which the Roman orator said raised the giver of health to man nearer to the Divine Giver of life—I know of no higher privilege than that of being permitted to address educated minds, of endeavouring to influence for good medical thought and opinion and practice, whether by the aid of the art of the printer, that "magic which embalms the thought," or by addressing such an assemblage as this, with the knowledge that what may be said before you (after as much careful preparation as the too scanty leisure of a very active life permits) will be carried as far as our language is read or translated. The honourable privilege, as rare as it is enviable, of addressing a great gathering of fellow-workmen, of corresponding pursuits and tastes, from whom one may confidently expect a sympathetic hearing and active response, can hardly be over-estimated. Much or little as we may know of each other, we are all united by the strong tie of professional interest; by the ambition to do well our daily work; and, I hope, by the desire so to make use of the meeting as to fuse temporary contact into durable friendship. I know that I see before me an assembly of no average intellectual standard. In days gone by, in this favoured district of our fatherland, there were "mighty men which were of old, men of renown," the generations who have helped to make Birmingham what it is—the Areopagus of the Midlands. So to-day, the men who still kindle its enthusiasm, still direct its energies, and are the master-spirits of its industry, its patriotism, its loyalty, are aided and influenced by a residential doctorate equal to the task of keeping such a population sound in body, sound in mind, and of thus economising the vast financial interests depending on its sanitary condition. The members of this Society now take the place, as a protective educational power, which was formerly filled almost entirely by the priest. Perhaps in many cases you do for the bodily health what is done by the rector or the nonconformist teacher for the moral direction of the parish. You are ready and willing to fulfil your high vocation, guiding your course of action as a beneficent, irrigating stream in the midst of a people whose bodily and mental welfare is entrusted to your charge.

What to say to such an audience is of course the first question. Of local affairs you know more than I do. Medical politics and controversial topics must be avoided. I have been told that you would probably be disappointed if I did not tell you something more of my own work—of what I have done and how I did it, why I did it, of my successes and my failures, how mistakes have become less frequent and progress more certain—than can be learnt from anything I have yet published. Acting on this hint, and knowing that in the minds of many of you my name is more closely associated with the practice of ovariotomy than with any other surgical question, I would first ask your attention to one phase in the history of the development of the operation which has been well termed the "revival of ovariotomy in England."

There are not many here who can carry back their reminiscences so far as mine go. Without being formally apprenticed, I had all the advantages of the old apprenticeship system under an unusually able and worthy man, the late Michael Thomas Sadler, of Barnsley in Yorkshire. For one year I lived with one of the parish surgeons of Leeds, attended the lectures of Hey and Teale, and saw much practice in the Leeds Infirmary. In 1837-38 I was in Dublin, under Graves and Stokes, Crampton, Beattie, Harrison, Apjohn, and Jacob. In 1839-40 I worked hard in St. Thomas's Hospital under Green, Travers, and Tyrrell. I obtained the prize for the fullest reports of examinations of the bodies of patients dying in the hospital during that period. But neither in the dead-house, nor in the wards or out-patient room of St. Thomas's, nor in Dublin, nor in Leeds, nor during my pupilage, can I remember ever having once seen a case of ovarian disease. I never heard a lecture upon the subject. Very little was said about it in any of the text-books, and the way in which it was introduced showed that it was not thought of sufficient importance for the attention of students to be drawn to it.

I very much doubt whether it ever formed any part of the examination at either the College or the Hall. We now know that, though Morgan, Key, and Bransby Cooper at Guy's Hospital, in 1839 and 1840, and Phillips at the Marylebone Workhouse in 1840, operated once, the matter was not in any way brought under the notice of the medical students of that time. I have no doubt that the operations at Guy's were done under the influence of Blundell, who had been professor of obstetrical medicine in that hospital. In the edition of his "Obstetrical Medicine," published in 1840, there is a chapter on ovarian dropsy very far in advance of the general knowledge of the day. To illustrate the routine treatment of the disease, he relates a characteristic saying of Abernethy, who, consulted on a case where tapping was useless on account of the viscid character of the contents of an ovarian cyst, said, "It won't do to go on boring holes in the belly." Probably Sir Astley Cooper's famous story of a case of "dry tapping" may be explained in the same way.

But I had not seen Blundell's book, and it was not till many years afterwards that I even heard of the name of McDowell, or of any of the fourteen cases of ovariotomy done in Great Britain between 1825 and 1839. It was not until I myself had written on the subject that I learnt what William and John Hunter had thought and suggested, or that John Bell had so lectured as to inspire McDowell with the determination to do what he afterwards did. In fact, I believe that most teachers and students of that day knew as little or cared as little about the subject as I did.

Very soon after becoming a member of the College of Surgeons in 1841 I entered the Royal Navy as assistant-surgeon, and for some six years served in the Naval Hospital at Malta. In addition to naval practice I saw many patients both male and female, and did many operations in consultation with resident practitioners in Malta. But I can only recollect one case, which I now believe might probably have been a case of ovarian tumour, but which at that time was a puzzle to us. My old friend Dr. Waters of Chester has lately reminded me that he and I had conversed on the subject of ovariotomy in Paris in 1848. But he spoke with knowledge acquired in Edinburgh under Hughes Bennett, I in complete ignorance. Still it is curious that we both came to the conclusion that, upon the facts as they then stood, ovariotomy was not a justifiable operation.

It was not until after settling in practice in London, which I did in 1853, that I ever saw a patient whom I knew to be suffering from ovarian disease. In 1854 I joined the Samaritan Hospital, at that time a dispensary for the diseases of women, a subject of which I knew less than of any other special division of our profession. In my young days I had done an unusual amount of midwifery, but latterly my practice had been almost exclusively surgical, with a strong tendency towards ophthalmic surgery. In 1853 or 1854 I became acquainted with Baker Brown. He occasionally came to the Samaritan Hospital, which he wished to join, and I two or three times saw patients with him at St. Mary's. In April, 1854, I and my friend Nunn of the Middlesex assisted Baker Brown in his eighth case of ovariotomy. This was the first time I had ever seen the operation attempted, and it certainly did not encourage me to look favourably upon ovariotomy. The patient died, and her death discouraged Brown. He, Nunn, and I talked the matter over, and I well remember Brown saying, "It's the peritonitis that beats us." His first three cases died, the fourth recovered, his fifth and sixth died, the seventh recovered, and the deaths of the eighth in 1854 and of the ninth in 1856 led him to cease operating for more than two years and a half, and again to advocate treatment by pressure and

Digitized by Google

iodine. He did not perform ovariotomy between March, 1856, and October, 1858.

When the Crimean War broke out I left London, served with the army in the East, and of course lost sight for a time of all the diseases of women. Any impression that I had received as to ovariotomy was certainly not favourable; but I did see cases of abdominal wounds which taught me that the peritoneum would bear much rougher handling than I had previously believed permissible. I had written about hernia, and had advocated division of the stricture without opening the sac whenever possible, simply to avoid the danger of admitting air or blood into the peritoneal cavity. But I learnt in the Crimea that a man's abdominal wall might be lacerated by fragments of shell, his intestines protruding and covered with mud, so remaining for several hours; and yet, that after careful cleansing of the cavity and accurate closure of the wounds, complete recovery was possible. When I returned to London in 1856 I was certainly much less afraid than before of abdominal wounds. I took up my work at the Samaritan Hospital again, but saw very few cases at first of ovarian disease. The first made a very painful impression upon me. Snow Beck tapped a very fine young woman, and injected iodine, he thought, into the cyst, but he really injected the peritoneal cavity. He had not taken the precaution of passing a long catheter through the short cannula of his trocar; the emptied cyst slipped off the cannula, and several ounces of tincture of iodine passed directly into the peritoneal cavity. Beck was grievously distressed, but the case did not so much deter us from the use of iodine as awaken us to the necessary precautions as to the mode of injection. But we had very few cases of ovarian disease, and it was not till December, 1857, that I made my first attempt to perform ovariotomy. A tolerably full report of the case was published at the time, and reprinted in 1865. Baker Brown was present and strongly dissuaded me from going on with the operation, on the ground that, as the tumour was behind the intestines, it could not be ovarian.

It is not easy to estimate correctly the part played by Baker Brown in the progress of gynæcology. In the minds of many his really great services have been overshadowed by the errors of his later practice. Some who fully acknowledge and admire what he did to popularise the operations for the cure of ruptured perineum and vesico-vaginal fistula, and who now recognise the great success which attended his adoption afterwards of John Clay's suggestion of dividing the pedicle of an ovarian tumour by the combined action of strong compression or crushing with the actual cautery, forget, or never knew, that when Brown assisted me in the case which I have just referred to, and in another which I am about to mention, his own early experience of ovariotomy had led him rather to oppose than encourage the repetition of the operation. At my second attempt, my first case of completed ovariotomy, Brown again assisted me, and in my first and in all subsequent reports of the operation I have fully acknowledged his zealous assistance. But it was not until after I had had three successful cases that Brown himself began to operate again, after an interval of more than two years and a half. At this third case Tyler Smith was present. He was greatly surprised at the successful result, and it induced him not only to cease the opposition he had formerly offered to Brown's practice, but to operate himself, which he did with great success.

I think it would be difficult to imagine a position more disheartening than that in which I was placed when making my first trials of ovariotomy. The first attempt, as I have said, was a complete failure, and strengthened, not only in the minds of others, but in my own mind, the fear that I might be entering upon a path which would lead rather to an unenviable notoriety than to a sound professional reputation. And if I had not seen increasing numbers of poor women hopelessly suffering, almost longing for death, anxious for relief at any risk, I should probably have acquiesced in the general conviction, have been content with palliative tapping, or making some further trials of incision and drainage, or of iodine injection, or of pressure, rather than have hazarded anything more in the way of ovariotomy. It may be forgotten now, but it is true that at that time everything was against the venture. The medical press had denounced the operation, both in principle and practice, in the strongest terms. At the Medical Societies the speakers of the highest authority had condemned it most emphatically. The example of the men who had practised it was not followed; some of them had given it up. Only once had a successful result been obtained in any of our large metropolitan hospitals, that by Cæsar Hawkins, at St. George's, in 1846, and he never undertook it a second time. Every other attempt, at Guy's by Morgan, Key, and Bransby Cooper, at St. Thomas's by Solly, had ended in death.

This was how we stood at the end of 1857. It was in February, 1858, that I completed the operation for the first time. I need say no more about it now than that it led to my being congratulated by Dr. West upon "complete success," and, with other evidence, to his thorough conversion from his previous condition of conscientious and determined opposition to a state of warm support both in public and private. Let me read to you part of a letter written by my friend Keith of Edinburgh. In the *British Medical Journal* in 1873 Keith wrote: "Few watched more eagerly than I did the history of this operation, and few know so well the details of the early cases. Till 1858 I could find nothing whatever anywhere to encourage, but everything to deter one from attempting it. Ovariotomy was then as an operation simply nowhere, and had the practice of using Dr. Clay's long intra-peritoneal ligatures been continued, it would have yet been nowhere. Up till that year Mr. Brown had lost seven out of his nine patients, and had ceased operating for upwards of two years and a half. Surely there was nothing for anyone to learn from such results, except, perhaps, what there might be to avoid." Keith was one of the first to follow me, and did more than anyone else at that time to assist in the revival of ovariotomy. I had done eight cases when he began, and ever since we have gone on side by side, very friendly rivals, assisting each other, comparing notes, not always running on the same track, but always equally anxious to perfect the operation. You all know how wonderful his success has been. Some of his later cases of the removal of uterine tumours are unsurpassed as surgical achievements. He concludes the letter, part of which I just read, by asserting, as others, both before and since, at home and abroad, have also done, and which it is my highest pride and pleasure to feel was not due only to their friendly feelings but because it is true, that the period of progress, "the revival of ovariotomy," began when the results of my earlier operations were made known, and the confidence of the profession was obtained by the publication of every case whether successful or not.

Anyone who will look over the reports of my early cases, who will see the names of the men who sent me their patients—West, Rigby, Watson, Acland, Hare, Stokes, and Oldham; of those who, as well as my colleagues, Savage, Priestley, Graily Hewitt, assisted me, or were present at the operations, among whom I may mention Paget, Fergusson, Tyler Smith, Bowman, Seymour Hayden, Pirrie, Baker, Grimsdale, Bickersteth; who discussed with me various questions which arose as to pathology and treatment, Aitken, Richardson, Ritchie, Hutchinson, Frank, Druitt, Robert Lee, Churchill, Beatty, and Simpson; who, for their personal assurance, like Nélaton, Worms, Demarquay, De Mussy, Péan, Courty, came from France; or De Roubaix and Boddaert from Belgium; or from Germany, as Schuh, Billroth, Esmarch; from Italy, as Porta, Vanzetti; or from America, as Gross and Marion Sims—will find no difficulty in understanding that we had now reached a turning-point. Some of these timely allies have finished their course. Some remain, ripened and matured by years of experience, not yet worn out, but finding their greatest happiness in their daily work, and in friendly association with their fellows and juniors. When I can name such men as not only having witnessed and sanctioned the operation, but becoming convinced, by following up the cases, that it was at least as successful as other serious operative proceedings, and when I add that many of these men soon began to perform the operation themselves, and publicly to advocate it—no one, I say, who considers all this will be surprised at the rapid rise and progress of ovariotomy between 1858, when it was revived, and 1864, when it was very generally accepted as a legitimate operation, and was not long afterwards cited as a triumph of modern surgery.

If I were to select from the books and pamphlets, most of which I have carefully preserved, published during these six years any one work which contributed more than others to form professional opinion, to awaken interest, and to instruct those who had before not thought upon the subject, it would be the tables of cases most industriously collected by your own townsman, John Clay, and published as an appendix to his translation of Kiwisch's "Clinical Lectures on Diseases of the Ovaries." The tables are now of far

Digitized by Google

more value than the lectures. One of Clay's chief merits is the example he set of obtaining all the information possible as to every recorded case of ovariotomy, completed or attempted, from the first up to 1860. He collected such a mass of facts, and arranged them for reference or study so conveniently, that he supplied us with fuller and more trustworthy information than had ever before been gathered together upon any surgical question, and I think he may be said to have done more than helped in starting what is now called the "collective investigation of disease."

From these tables as arranged by Clay, and from a perusal of the works published about that time, we can now see how fully the principles and many of the practical details concerned in the matter had been discussed. What may be called the ethical or moral side of the question had been fully argued. The fears and forebodings as to the physical and physiological effects of the removal of an ovary—such as the abnormal accumulation of fat, the development of masculine type, and the restriction of the sex of infants—were dispelled and falsified. The causes of death in fatal cases had been investigated. Many of the mistakes of the earlier operators had been corrected; and, far above all other things, the profession had gained confidence in the accuracy and completeness of the facts laid before them. The old plan of operating in a hot moist chamber, and keeping the room over-heated for days afterwards, was seen abandoned. The semi-recumbent position of the patient was exchanged with great advantage for the horizontal. Safer anæsthetics than chloroform were used. Simple bandages for keeping the patient quiet supplied the place of an objectionable crowd of assistants. Precautions, never before thought much about, were taken for protecting the patient from any infectious disease; by obliging every visitor intending to be present to declare that he had not made a post-mortem examination, nor been into a dissecting-room, nor attended any case of infectious disease within a week; by the utmost attainable purification of the house, room, bedding, and clothing, sponges, and instruments—in fact, of everything brought near the patient—and all this was insisted on with a pertinacity which often gave offence. A great deal was gained by shortening the incision in the abdominal wall, by emptying the cyst before drawing it out, or by lessening the bulk by breaking down the septa of multilocular cysts; by extreme care in preventing the entrance of ovarian fluid into the peritoneal cavity, or by very carefully cleansing the cavity from any blood or fluid which had entered it—a process christened by Worms the "toilet of the peritoneum." Sir Benjamin Brodie long ago remarked with regard to lithotrity, that success depended upon attention to a number of minute details. So with ovariotomy. No one of the details which I have just alluded to may be alone of any great importance, but taken together they did a great deal towards preventing failure and securing success. Other modifications of more or less importance were soon made. The old vegetable material for ligatures and sutures, coarse whipcord or twine, was abandoned. After many trials of silver, iron, or platinum wire, horsehair, fish-gut, and other materials, we settled upon pure silk as the most useful and trustworthy, and proved that, after a few weeks' retention in the animal body, it entirely disappeared. The mode or process of its removal by the insinuation of white blood-corpuscles between its fibres, a sort of untwisting or solution, was watched stage by stage, and long before the treatment of the pedicle in this manner was seriously proposed, we learnt that silk ligatures, and portions of omentum secured by them, might safely be left within the abdominal cavity. Nathan Smith was the first to treat the pedicle in this way, but he made his ligatures from a leather glove. Tyler Smith was the first to revive the practice, using silk. A story has been very generally believed—probably some of you may have heard it—that Tyler Smith's first trial was accidental; that he cut off the ends of the ligatures inadvertently, forgot all about them, and was surprised to find that his patient recovered. But on inquiring of his former assistant, Dr. Edwards, who is still in practice in London, I am assured that there is no ground for this story. The operation was performed in June, 1861. Dr. Edwards writes: "Previously to this operation I had strongly advocated the advisability of dropping the pedicle and cutting short the ligature, and it was at my initiation that it was done. In fact, I did it myself."

The mode of treating the pedicle became a subject of anxious discussion. The evils which attended the use of the long ligatures were soon found to outweigh any advantage obtained by their service in drainage. The extra-peritoneal method was simplified by Hutchinson's introduction of the clamp, and for a long time it was only in cases where the clamp could not be used that any other method was sought for. I had hoped much from the écraseur, but only used it once. Others had spoken of crushing the pedicle and twisting off the cyst. I had an instrument made for tearing through it, a rough bluntish saw. But all these plans, without much trial, gave way before that combination of crushing and cauterising for which surgery will be for all time indebted to your own Clay. Used at first by him for dividing omentum, both he and I suggested that this might be a good mode of dividing the pedicle in ovariotomy. Baker Brown was the first to carry out this suggestion in practice, and with immediate improvement in the results he obtained. Keith followed him, and, with occasional intermissions, has continued the practice. I also had very good results in thirty cases, and have sometimes blamed myself for not having given it a more extensive trial. I did not give it up, however, until I thought I had proved the ligature to be more trustworthy in cases of short pedicle. What is called the complete intra-peritoneal ligature—by which we mean the transfixion of the pedicle, tying it in two or more portions, cutting off the ends of the silk close to the knots, and returning them with the tied stump after cutting off the cyst—was by no means a common practice until long after the date of which I have been speaking.

The mode of closing the opening in the abdominal wall was one of the first things to attract my attention, and no one before me seems to have cared whether the peritoneum was included in the sutures or not. A very few still maintain that it is a matter of no consequence, and Kœberlé still asserts that it is better not to include it. I have not time now to trouble you with a thrice-told tale of how, by examination of patients who died after ovariotomy, and by experiments on animals, I convinced myself that by passing the sutures through the whole thickness of the abdominal wall, including the peritoneum, at such a distance from the divided edges as to permit two surfaces of the serous membrane being brought into contact when the sutures were tied, instead of merely bringing the edges together, a more permanent and complete union was obtained, and that one source of immediate danger was avoided—I mean the oozing into the abdominal cavity of blood, or serum, or fat from the divided tissues. So, too, we got rid of the inconvenience which patients who recover sometimes suffered from the adhesion of omentum or intestine to the abdominal wall.

I need not say much about the mode of dressing the wound, but I think it is of some importance to note that from the first I was very careful to keep the wound as dry as possible. I had become convinced in my naval and military practice that water dressing and other moist applications (without going into any discussions as to the cause of pyæmia) were far inferior to dry dressing. For several years I used pads containing Skinner's mixture of calcined oyster-shells and oil of tar, covered with layers of cotton wool, and supported by the gentle pressure of a flannel bandage; and the only modification, made of late years, in these dry dressings has been the substitution of the elegant and comfortable pads devised by your townsman, Gamgee, for the antiseptic and absorbent powder of Skinner.

The chief improvement made in the after-treatment was in greatly diminishing the amount of opium. Large doses had often injured the patients, and I thought might have been the cause of death in some of the earlier cases.

(To be concluded.)

ST. GEORGE'S HOSPITAL.—The following prizes have been awarded to students in the Medical School for the session 1883–4:—For the William Brown Exhibition of £100, Mr. E. C. Arnold and Mr. Allingham were equal; the William Brown Exhibition of £40 was won by Mr. A. Codd, the Brackenbury Prize in Medicine by Mr. C. Bell, the Brackenbury Prize in Surgery by Mr. R. Pinhorn, the Treasurer's Prize by Mr. R. Pinhorn; the Serjeant Thompson Medal by Mr. Trevor, the Pollock Prize in Physiology by Mr. A. H. Vernon, Sir Charles Clarke's Prize by Mr. R. Emmett; general proficiency prizes to pupils in their first year, Mr. Ernest Lancaster; second year, Mr. W. L. Dickinson and Mr. De Nyssen, equal; proficiency prizes to pupils in their third year, Mr. K. Kirkpatrick and Mr. G. F. Smith, equal; certificate of proficiency in Medicine, Surgery, and Pathology, Mr. C. F. Glass.

Clinical Lecture

ANKYLOSIS AFTER CHRONIC JOINT DISEASE.

BY RICHARD BARWELL, F.R.C.S.,
SENIOR SURGEON TO CHARING-CROSS HOSPITAL.

GENTLEMEN,—I told you in my last lecture that in bad cases of chronic joint disease a certain impairment of mobility will result. As a sequela of the less severe forms of synovitis, this may be due to fibrous thickening of the synovial and perisynovial tissue. The more severe forms, and osseous diseases which have been allowed to run on and affect the joint itself, end commonly in ankylosis, false or true, which is often the best or only means of cure. The first two modes of impairment—viz., synovial with perisynovial thickening and false ankylosis—are more or less inconvenient, according to two factors: to the amount of immobility and to the place in angular mensuration of the arc. Let us take as examples in marked contrast with each other the elbow and the knee, both of which we will suppose to be capable of moving through an arc of 35°. If, in the former case, this movement occurs on each side 90°, so that the angle of the joint may vary from 73° to 107°, the use of the arm for most occupations will be very little damaged; but if a like amount of movement at the knee were relegated to the same part of the arc the limb would be quite useless; whereas the value of an arm would be greatly depreciated if its movement of 35° were restricted to the best possible position for the knee—viz, from 180° to 145°. But, again, immobility, very much greater than that above supposed, may be of itself a serious detriment.

Thus the surgeon will have one of two causes for interference: either great restriction of mobility, or the unfortunate position in which movement is permitted, and not unfrequently both these conditions are combined in the same case. In both we may in great measure, or entirely, eliminate the inconvenience by a surgical procedure named forcible flexion or extension, as the case may be. These operations are known in surgery sufficiently well to exonerate me from any close description here; I will only tell you that in certain cases tendons, more especially of the flexors, may require division; that the forcible movement is not a mere application of bodily strength, but is directed and governed by certain rules of art, differing with each joint and with every position of such joint. You should, however, learn to distinguish the conditions, which enable you to promise very considerable restoration from those which would cause you to encourage only hopes of less advantage. Remember, too, that there are many cases in which, though you may be unable to greatly increase the amount of mobility, you can at least cause it to take place in a more convenient position. You will perceive readily enough how important it is that, before recommending any such operation, you should be able to tell your patient what he will in all probability gain by it, and you will also see that the question divides itself into two heads: operations proposed for the restoration of mobility, and operations intended only for the correction of position. As to the former of these points, I give you now some axioms which will enable you to judge with great accuracy what you will be justified in predicting.

Provided that no subluxation nor altered form of the bones obtains, very considerable, sometimes complete, mobility may be restored; when the inflammatory attack has not been prolonged; or if it have been sharp, rather acute, and unaccompanied by marked pyrexia; when whatever movement remains is smooth, normal in direction, and free within its limits, the impediment being sudden; when, the impediment being reached, a rather acute pain is experienced. Under the same conditions of bone, less, but still some useful, mobility may be gained, even though the original disease has been rather more chronic; when already a certain amount of mobility (20° for example) is possible, though that motion is in no part of its course free, but impeded, the resistance increasing *pari passu* with the amount of change in posture, until not a sudden but a gradual check is reached. If the patient be warned that he may be required to undergo, and will submit to, one or more repetitions of the stretching, much more may be effected than in a single operation. Less mobility is obtainable by forcible stretching, if a protracted disease have left, together with a certain but not very great change in the shape or relationship of the bones, only a small amount of much impeded movement. Yet if that movement be in an inconvenient portion of the arc, the posture may often be so changed that the limb and its movement shall be in the most convenient situation.

Forcible extension and flexion can do no good, but may prove absolutely injurious if the form of the bones be much modified or their relative position considerably altered.[1] To this I need hardly add that such treatment is not applicable to true ankylosis. But I am very far indeed from telling you that this last class of cases is beyond the aid of art, or that lameness due to inconvenient position of completely stiffened limbs should be abandoned or left without remedy.

Let us take as our first example a knee with true ankylosis at a right angle or less; consider the condition of such patients as I have often shown you, and show you now again; observe the exaggerated and very unsightly limp; remember that the deformity does not remain confined to the limb, but that the spine and trunk, being, to allow of progression, thrown into awkward postures, soon become curved and twisted; therefore that the patient more or less quickly, according to age, becomes, not merely a cripple, but a deformed cripple. Obviously therefore it is the surgeon's duty to rectify the posture of the leg—i.e., to place it in a straight line with the thigh. This may be done by osteotomy—i.e., by dividing the femur just above the condyles, placing the tibia in a good position, and applying at once a plaster-of-Paris bandage. After such operation the patient may as a rule get up in from four to six weeks, but it is prudent that for two or three weeks more a poroplastic or leather splint should be worn during walking lest the union should bend. I must tell you, too, that a knee-joint disease occurring in early life and severe enough to have produced true ankylosis will also have checked the growth of the bones; therefore you should measure the length of the femur and tibia against those of the opposite side, and warn your patient of the amount of inevitable shortening, otherwise some subsequent disappointment may result. You have seen me treat very many cases of true ankylosis after this method, and you will have observed that in no instance has the operation caused the temperature to rise above 100° F. From this you may estimate the safety of the operation, but can judge still better when I tell you that I have divided seventy-three femora without having had a single untoward result. As to estimating the ultimate effect of these operations, students at a hospital, and for that matter surgeons also, lie under the disadvantage that when wounds are healed or bones united they very often see nothing more of the patient and the effect of the procedure on his after-life is generally unknown. Those of you who have followed my practice for the last few years will remember that of the many cases I have thus treated several have come from two homes for cripples with which I am connected, and I have within the last few days seen those patients. They are all walking with a barely perceptible limp, and all without artificial aid of crutch or stick, except two, whose treatment is still too recent to allow unassisted progression. I will moreover, relate to you a case from my private practice, because I have had the opportunity of watching it for a length of time, which warrants my affirming that the improvement is permanent.

In February, 1880, I was asked to visit at a sea-side town a lady suffering, I was told, from severe spinal curvature. I found her, aged thirty-one, somewhat stout, pale, and feeble, reclining on a sofa, which she only quitted once in the day to go out in a Bath chair. She complained of a great deal of pain in the back and loins, aggravated by walking, even if only about the room. In order to examine the spine I got her to stand up, and finding that one leg was lame, elicited that when nine years old she had scarlatina, followed by synovitis and suppuration, culminating in true ankylosis of the knee in a position rather less than a right angle. I need not here detail what was done for the spine. Suffice it to say that I fully explained that all such measures could be but palliative while the false position of the

[1] At the knee more especially a subluxation of the tibia backwards almost entirely precludes such procedure.

Digitized by Google

ankylosed limb continued. It was, however, rather more than a year before the lady and her friends determined to follow my advice. In March, 1881, I divided the femur just above the condyles, and placed the tibia in a line with the femur. She remained in bed a month, and another fortnight in town; she was then supplied with crutches and with a high boot to compensate the loss of growth in the limb bones; also with a light poroplastic splint. She learned to walk, though rather slowly, for she had not really walked for more than twenty years. For the last two years and a half she has walked well without any stick or other support. She is strong and healthy, enjoying life and fond of exercise; the limb, formerly emaciated, is now plump and well formed; the spine is very nearly straight, and when I last saw her, about six weeks ago, she was in robust health, and going for a pleasure excursion up the Thames. But, as I pointed out to you just now, false ankylosis in a bad position does not permit of treatment by forcible extension when the bones are much altered in form or when their relative position is considerably changed. The modifications of form which preclude that treatment are such as affect the joint surfaces; they are, if not to be actually verified by touch, to be surmised with certainty if you find the edges of those surfaces either elevated in ridges or scooped out by old caries into hollows, while depressed cicatrices prove previous suppuration, and awkward twists or lateral deflections of the lower limb segment indicate loss of substance on one side or the other. In such cases, even if we could, which is doubtful, place the limb in a better posture as regards flexion or extension, it is impossible to predicate whether we might not at the same time increase the lateral or the rotation deformity.

Again, as regards subluxation sideways of a tibia, interference by forcible extension is extremely likely to increase that trouble, or, still worse, to rupture the altered ligaments, so that the leg becomes entirely loose on the thigh, and more useless for support than before the operation. The more common posterior dislocation requires some little care in diagnosis. We are supposing a case of false ankylosis at about a right or at a smaller angle, in many of such the femoral condyles project considerably beyond the anterior edge of the tibia, sometimes because that bone has been really displaced some distance backwards, sometimes because the leg, having been long kept in flexion, no pressure has fallen on the end of the thigh bone, and the condyles have therefore become prolonged by unresisted growth. I advise a careful diagnosis; but am bound to tell you that in both these circumstances forcible extension of the limb is inadmissible, as posterior dislocation almost certainly follows. But in these cases, whether of change in bone surface, of lateral or posterior dislocation, you may, by the help of osteotomy, procure a straight and useful limb; moreover if, as often happens, some awkward twist, either abduction or adduction, of the tibia has occurred, you may at the same time rectify that condition.

Let me call your attention to this girl. Nineteen months ago I performed that operation for her; the knee was falsely ankylosed, very much bent, abducted and rotated outwards; she was exceedingly lame. Now you see the limb is straight, the foot does not turn out, and the slight mobility permitted by the false ankylosis is of great advantage to her, as the extremity of the limb can be bent or straightened to about the extent of four inches, which improves her gait and her appearance in sitting. The slightly heightened shoe enables her to walk with only a very little limp, her spine is straight, and her health is re-established.

NURSES FOR THE SICK POOR.—The Whitechapel Board of Guardians have recently had under consideration the question of the desirability of securing, by means of the employment of a limited number of non-salaried pupils or probationary nurses, a greater degree of elasticity in the nursing arrangements of the infirmary, under circumstances of illness, absence, &c., as well as the preparation and training of suitable persons for permanent appointments. A committee of the Board has expressed the hope that the Local Government Board will see fit to relax existing rules so as to admit of the reception of such nurses, and the provision for them of the usual allowances, without report to, or approval by, the Board, as in the case of the staff appointments.

ON THE

NERVOUS OR MUSCULAR ORIGIN OF CERTAIN SPASTIC CONDITIONS OF THE VOLUNTARY MUSCLES.

By SYDNEY RINGER, M.D.,
PROFESSOR OF MEDICINE AT UNIVERSITY COLLEGE, LONDON,
AND
HARRINGTON SAINSBURY, M.D., M.R.C.P.,
ASSISTANT PHYSICIAN TO THE ROYAL FREE HOSPITAL.

(*Continued from p. 768.*)

WE must now make the attempt to localise the disease, but before doing so we must draw attention to the fact that whilst the voluntary muscles are affected in this widespread and symmetrical fashion, the muscles of organic life escape wholly. Nowhere do we find any record of a difficulty in swallowing, or of trouble in micturition or defecation; this is of importance, for our *peripheral* search for a cause has been completely negative; we have been left with nothing but the bare symptom—muscular rigidity. Bernhardt's analysis is very clear, and we can scarcely do better than follow it. He points out that the disease is not a local one, in no case is a leg or an arm alone affected. The muscles suffer generally and symmetrically. The distribution of the hypertrophy recalls very much the disease pseudo-hypertrophic paralysis; but leaving out of account minor differences, the complete absence of paralysis and of any trace of atrophy in any part of the body, as well as the negative results of microscopic examination, at once dispose of this possibility, as also of all those cases in which a true muscular atrophy is masked by an overgrowth of the interstitial fibrous and fatty elements (lipomatosis masculorum luxurians) such as may occur in progressive muscular atrophy. In relation to this progressive muscular atrophy, we must state that Seeligmüller in one of his cases records fibrillary contractions of the affected muscles, but he at the same time emphasises the fact that there was no question of atrophy present.

With the elimination of all atrophic states, and likewise all paralyses, we have left but few possible cord affections, and in keeping with this is the entire absence of rectal or bladder trouble. Again, although in Thomsen's disease we have evidence of the face muscles and those of the tongue and eyeball being implicated, still we have no trace of an affection of the medulla such as we meet with in glosso-labio-laryngeal palsy, yet such symptoms we should expect if a lesion of the cord had been the cause, and had extended upwards in amongst the nuclei of the medulla. Almost the only region of the cord in which it would be possible to locate a lesion giving rise to symptoms like those here present are the lateral tracts; a lateral sclerosis would cover many of the symptoms, and would associate this disease with those forms of spastic paraplegia in which a lateral column affection is probable. This is Seeligmüller's view; but even here we have against such view the almost insurmountable objection that in Thomsen's disease there is no evidence of loss of power; and then, too, the rigidity characteristic of lateral sclerosis is of quite a different kind; it tends to become permanent as the disease advances, and *does not wear off with exercise of the affected part*; indeed, it is quite impossible to find any likeness between the walk in Thomsen's disease and the spastic walk of lateral sclerosis.

There remains the encephalon in which to search for the cause. But again we must record negation. Thus, though the speech is difficult, yet "there is neither stammering nor tripping up over syllables. All the other cranial nerves are unaffected. The organs of sense functionate normally; the psychosis is without anomalies."[1] Thomsen, in his original paper, suggested the name "muscular ataxy," but none have followed him along this track; and of ataxy or incoördination no other author makes mention.[2] In Thomsen's family history, while the affection itself was well marked in three generations, a neurotic history was traceable in four; this, in conjunction with the observation that the degree of manifestation of the trouble was much increased by psychic disturbance, such as any sudden emotion

1 Bernhardt, *op. cit.*, p. 530. 2 Ibid., p. 529.

Digitized by Google

(we have here Dr. Thomsen's personal experience), led him to consider the disease as of the nature of a psychosis; hence he names the disease, "tonic contractions in voluntary muscles, the result of an inherited psychic disposition."[3] This view is unsupported by any of the succeeding authors, nor do we think that it is tenable in view of the whole facts of the case.[4]

The attempt to localise the disease has not been very successful. We have been driven from the peripheral structures to the cord, from the cord to the medulla, from the medulla to the encephalon, and have not found the morbid action. We have accordingly no other course open to us than to try back. May it be that, after all, the muscular fibres are themselves at fault? The microscope has detected nothing morbid; the electric reactions have revealed peculiarity, but nothing of the nature of morbid reaction as we are familiar with it; and, finally, the vigour of contractility of the fibres is unimpaired. Bernhardt, nevertheless, does hold the muscular fibres to be at fault. His suggestion is that we have present not morbid action but anomalous action, this anomalous action being the result of an arrested development. A faulty evolution inherited or congenital he holds to be at the bottom of the affection. In support of this theory he instances the observations of Soltmann[5] on the contraction curve of the muscles of newborn animals. This curve is lower, the top is flatter, the slope, in particular of the descending limb of the curve, is more gentle. The curve resembles that of fatigued muscles. He also draws attention to the occurrence in certain animals, rabbits, and certain fish of striped muscular fibres of two varieties. In the rabbit there are the red and the white muscles, and of these the white are characterised by the suddenness of their contraction; the red by the great prolongation of the contraction curve, and the fact that once tetanised the relaxation takes place only very slowly, though the tetanising influence have been withdrawn. Ballet and Marie follow Bernhardt in localising the affection in the muscles, but they go no further. Leyden, in his remarks on muscle rigidity, also considered the muscular fibres to be at fault, and threw out the suggestion of an increased consistence of the contents of the sarcolemma, "analogous to a rigor mortis,"[6] as possibly explaining the phenomenon, but he appears to be referring to muscle rigidity in general and not to this special disease, which indeed he does not appear to have recognised as something quite distinct from the rigidity accompanying cord diseases. Seeligmüller made an almost identical suggestion in his first consideration of the disease, but subsequently renounced this view in favour of an affection of the lateral tracts. In a note having reference to Bernhardt's view of the nature of the disease, he thinks that a congenital or inherited faulty evolution of the lateral tracts will equally meet the facts of the case. We have mentioned the objections to this view; we may add another—viz., that exaltation of the reflexes (patellar, &c.) has not been described as characteristic of Thomsen's disease, yet these have been investigated. This negative evidence is of importance, since much stress is laid on the condition of the reflexes in lateral sclerosis.[7] We think then that, on the whole,[8] the evidence is against a neuropathic, and for a myopathic, theory; but admitting this, Bernhardt's suggested arrested evolution yet remains to be considered. This we shall do, however, after we have brought forward the experimental results which we think bear on the question. We may at once proceed to these.

During the course of some experiments with the phosphate, phosphite, and hypophosphite of sodium upon the frog,[9] some very curious effects on the muscles were noticed. These consisted in fibrillary twitchings of the voluntary muscles, quite like those induced by veratria, and very similar to those observed in progressive muscular atrophy. These movements varied much in intensity, in some cases showing only as a flickering of the smaller bundles of fibres, in others being so extensive as to move even a whole limb. The movements in these latter cases were quite choreic in type, but the gradation between such and the finer fibrillary movements was so insensible that the conclusion was inevitable that the cause of the one was the same as that of the other, and hence that if the fibrillary effect was a peripheral one, the larger choreic movements were likewise peripheral. Whilst apparently quite involuntary in their nature, it was observed that voluntary movements would bring out or greatly increase these fibrillary contractions.

At this stage and later the movements of the animal were observed to be very slow and stiff, the relaxation following a contraction being very much delayed, quite recalling the action of veratria and some other muscle poisons. This muscular stiffness reached its maximum when a complete saturation of the system with the salt had obtained. At this stage a voluntary movement would cause the hind-limbs to become rigidly extended, and in like manner the toes extended and spread; simultaneously the fore-limbs would be flexed across the chest. The effect so far was very like that of strychnine, but there were decided differences—e.g., the strychnine rigidity is followed by a lapsing of the limbs into a state of relaxation, from which a fresh stimulus again starts them into rigidity. This sequence may be many times repeated; quite different is the sodium phosphate rigidity, for this after persisting some time only very slowly gives way, but having given way the relaxation is maintained. Another difference observed consisted in the involuntary nature of the strychnine spasm, this indeed being nothing else than a very widespread and violent reflex, whereas the sodium phosphate rigidity was observed to be closely related to volitional movement—in fact to supervene upon it,—though one could not regard it as actually of voluntary nature.

(To be concluded.)

CHOLERA.

BY MAX VON PETTENKOFER, M.D.,
OF MUNICH.

(*Continued from p. 771.*)

WE shall now inquire into the time relations of cholera at its permanent home in Lower Bengal. Dr. John Macpherson has, in his work on "Cholera in its Home," tabulated the number of cases of death from cholera in Calcutta for each month of the year for a period of twenty-six years. I have calculated and arranged in a tabular form from these statistics the average number of deaths in each month, and contrasted each month with the average rainfall at Calcutta. (See Table I.) It will be seen how unequally distributed is the great fall of rain, which is two or three times greater than in many districts of Germany. Calcutta has a rainy season, which begins at the end of May and ends at the beginning of October. The cholera decreases from the beginning and increases again towards the end of the rainy season. It reaches its maximum during the driest and hot months (March and April), and its minimum is attained during the wettest and hot month of August, so that the curve of cholera falls whilst that of rain rises. The rise and fall of endemic cholera is constant, whilst the prevalence of cholera in its epidemic form is very variable. In the Punjaub the rain winds (monsoons) bring with them the cholera. This apparent contradiction of the experience above mentioned may be explained by considering that the monsoons bring to the Punjaub the necessary moisture which is believed to be requisite for the development of an epidemic of cholera. Rain falls in the Punjaub at the same time as in Lower Bengal, but in smaller quantity. The average rainfall at Lahore is 22 in., as compared with 62 in. at Calcutta; so that in Lahore for the greatest part of the year the soil is too dry for cholera. That these claims are substantial will be granted by a study of the rainfall and related circumstances in other parts of India. This is well seen at Madras, as indicated by Table II. At Madras the average rainfall is about 48 in., and is therefore midway between those of Lahore (22 in.) and Calcutta (62 in.), but the quantity of rain in the several months is different. The greatest quantity of rain falls in November, and Madras is not under the influence of the south-west, but of the north-east monsoon, and the rainy season extends from July to December. As Madras lies further south than Calcutta, and the quantity of rain is 25 per cent. less, it is

Digitized by Google

plain that the desiccation during the dry and hot season would be much greater there than in Calcutta. And this state of affairs is reflected in the vegetation. April, May, and June are like winter months; the leaves begin to fall; the verdure fades away, and the sap descends to the roots of the trees, not because of the cold, but on account of the excessive dryness. It is at this period that cholera is at its minimum. In July, when the rain begins to fall, cholera increases, and reaches its maximum in August. The rain continues, but the cholera decreases owing to the excessive dampness of the soil; so that in November a second minimum in the number of cases of cholera is met with.

In order to inquire into the accuracy of these views, another observation, taken from India, may be cited. Places which are outside the region of endemic cholera, and which have a rainy season at the same time and of about the same amount as Calcutta, have the same amount and periodicity of cholera. Such an instance is afforded in Bombay, which is a city as large as Calcutta, and the rainy season of which depends on the south-west monsoons. In a table which shows the frequency of cholera, the rainfall, and the temperature on the average for a period of fifteen years, it is evident that in all three particulars there is a remarkable correspondence between Calcutta and Bombay. (See Table III.)

The temperature has been given for the reason that it brings out the fact that temperature has not much influence on the progress of cholera. That Bombay is not within the endemic area of cholera is sufficiently testified by the results of the statistics for fifteen years. During this period there were three years in which no epidemic occurred. That a whole year should pass without the occurrence of a single case of cholera in Bombay is not to be expected, when the active intercourse between it and the endemic areas is borne in mind. If the table of averages relating to Bombay be compared with that of Calcutta, the resemblance is seen to be striking. The maximum incidence of cholera is seen to occur in both in April, and the minimum is found in Calcutta in August and in Bombay in September. After this minimum the increase takes place equally in both cities. The years during which no epidemic occurred in Bombay were characterised either by too much wet or too great dryness. Thus in the years 1852-53 the diminished frequency of cholera followed on a period of great wetness, and that of 1860-61 came on after a very dry season. That this dependence on the weather is really sound is shown by a study of the years immediately following the lessened intensity of cholera. The years 1853-54 and 1861-62 in Bombay showed the same rhythm for cholera as Calcutta; whereas, on the contrary, the year 1858-59 in Bombay had the same abnormal rhythm as Lahore. The average number of deaths from cholera in Bombay in March was 253, in April 295, and in May 294. In June, when the monsoons begin, the number further diminishes. The number of deaths in March, 1859, was 9, in April 7, in May 69, and when in June the monsoons set in and 26·8 inches of rain fell, the number rose to 843, whilst the mean for June was only 278. After dry weather Bombay also shows, like Lahore, "monsoon cholera."

Cholera in India, as is well known, has likewise a remarkable relation in time to the years of drought in India. If rain once fail, or be very small in amount, a famine necessarily follows. Distress is then felt both in Lower Bengal and in the Punjaub, but the cholera only appears more severely in Lower Bengal and avoids altogether the Punjaub. The dependence of epidemics of cholera on the time of the year (i.e., on the moisture of the soil) comes out well in countries outside India, as, for example, in Germany. In the kingdom of Prussia from 1848 to 1860 cholera was prevalent every year, though its incidence varied in intensity and in different provinces. During this period, cholera was as much at home in Prussia as in India. Brauser has collated the cases of death from cholera week by week for the thirteen years 1848 to 1860. The numbers for the different months are as follows:—April, 112; May, 446; June, 4392; July, 8480; August, 33,640; September, 56,561; October, 35,271, November, 17,530; December, 7254; January, 2317; February, 842; March, 214. The numbers are founded on statistics, and it is proper to investigate the possibility of errors therein. No objection can be made to the Prussian statistics, for the numbers are too great to be vitiated by casual error. In India the statistics may not be so trustworthy, because registration is sometimes defective. Some cases of death from cholera may not appear as such, and perhaps some deaths may be falsely registered as due to cholera. The Indian statistics have, therefore, only been given for large cities, where more attention is paid to correct registration. The errors which may occur extend over all the months of the year, and are scattered, so there is less liability to perversion of the truth. And there is no need to prove absolute numbers, for relative statistics are sufficient. Further, in the garrisons and prisons of India, where physicians abound, the statistics are nearly as good as in Germany, since cholera is a disease so easily recognised. That a large series of numbers is able to eliminate to the vanishing point the unavoidable errors of statistics is shown by an instructive example of the statistics of typhoid fever in Munich. Buhl, in studying the relations between the

occurrence of typhoid fever and the state of the subsoil water, made use only of figures obtained from the general hospital during the years 1856 to 1864, where every diagnosis was confirmed or overthrown by post-mortem examination. [Pettenkofer here devotes considerable space to the discussion of the question, dealing chiefly with the possible inconsistencies in the certificated causes of death. He seems to prove that the difference between the numbers gained by actual observation and those obtained by calculation is so small that it may be disregarded.] It is considered that since the rate of death from typhoid fever in the general hospital is on the above showing a fair representative of the death-rate in the town of Munich, so the numbers concerning cholera obtained from the barracks and prisons of India may be taken as a good sample of the rate of mortality from cholera in the cities themselves. Bryden has given support, in his work on the time and space distribution of cholera in India, to the reports of barracks and prisons. That cholera should attain its greatest frequency in North Germany during the months of August, September, and October, and that winter should seldom see an epidemic, may be explained by the temperature which prevails in the air and earth. In the class of ectogenous infectious diseases, to which cholera belongs, the temperature, as in all organic processes, has a decided, though it cannot be the chief, influence. That cholera is not very dependent on temperature is evidenced by the possibility of the occurrence of an epidemic of cholera during the winter. Why cholera spreads more during the summer and early autumn, as compared with winter and spring, must depend on other causes than temperature.

It is clear, in my opinion, that the soil and the moisture of the soil play a principal part. The dampness of the soil is, under certain conditions, clearly related to the subsoil water, "Grundwasser." Epidemics of cholera abound during the time that the "Grundwasser" is falling, when the earth is comparatively dry. By "Grundwasser" is to be understood that condition of dampness of a porous soil when all the pores are filled with water. If water and air together fill up the interstices, then the soil is called simply damp. I have so long and so often spoken on the influence of the rise and fall of the ground water on the frequency of typhoid fever and cholera, that I imagine a great many scientists credit me with the view that subsoil water is highly harmful. But such is not the case. The subsoil water is merely an indication of what is going on, and has no more to do with the actual processes than a dial and the hands have in the going of a clock. The fall of the ground water by pumping away, or the rise of ground water by the damming of a stream, has not the least effect on typhoid fever or cholera in the neighbourhood. The observation of the level of the surface of the water in springs as an indication of the state of the subsoil water is of no value from an etiological point of view, unless the spring be independent of the nearest watercourse, and unless at the time of the observation the real state of the spring is a true reflex of the condition of the subsoil water in its neighbourhood. When the information, however, is obtained properly from springs free from objection, then the condition of the ground water gives the state of moisture and of exchange in the overlying layers much more accurately than an observation made on the atmospheric downfall (rain and dew). Rain may fall for a week without causing any rise in the subsoil water, and again a rise may occur when there has been no fall of rain for some time. The perusal of Professor Franz Hofmann's work, published in the Archives of Hygiene, on the movement of subsoil water, may be safely recommended. When an epidemic of cholera occurs in winter, then a relatively low state of the ground water is found to prevail. In Munich three epidemics prevailed during the cold months: the first occurred between October and March, 1836–37; the second from July to November, 1853–54; and the third from July till April, 1873–74. All three epidemics were associated with a relatively dry state of the earth, as was proved also by meteorological data concerning the rainfall. No investigation had been made as to the state of the ground water during the period 1836 to 1854, but this investigation was first begun in 1856, so that for 1873 and 1874 the data were available; and it is only on the assumption that the condition of the soil as regards moisture was abnormal for the time of year that the long duration and strange division of the last epidemic could be accounted for. The subsoil water sank from the end of June, 1873, till the beginning of August. On that occasion the germs of cholera probably came from Vienna, where the epidemic had prevailed since April. Two cases coming from Vienna, one in June, the other in July, could be vouched for. At the end of July the first illness from cholera occurred in Munich, but in individuals who had never come in direct contact with the infective cases. In every fresh outbreak, in 1836, in 1854, and in 1873, the same part (the north-east) of the town was the first to suffer. As the epidemics of 1854 and of 1873 developed at the same time of the year (the end of July), so by the middle of August the height of the epidemic was reached; it then fell off rapidly during September; during the whole of October only isolated cases occurred; and by the middle of November the epidemic had ceased in the higher lying parts of the town. It was thought that the disease had become extinct, and notwithstanding that it was considered strange that the summer epidemic had chiefly fallen upon the higher lying parts of the town, whilst the lower lying districts on this occasion had been altogether spared. In the middle of November, when the weather became colder, the epidemic reappeared, and attacked chiefly those lower lying districts which had escaped in the summer. It is impossible to trace the progress of contagion in time and space from one individual to another. The contagionists cannot maintain that the unexpected falling off of cholera was due to the protection afforded by the previous prevalence of the disease, seeing that the lower lying districts had escaped the epidemic, and that the other inhabitants two months later suddenly lost their protection. Anyone who studies the movements of the ground water in Munich for the year in question will find that in the first half of August an event occurred which in suddenness and unexpectedness rivalled the retrogression of the epidemic in the second half of August. In the first half of this month there fell an abnormally large quantity of rain (171 mm.), which excessive rainfall was the largest amount ever registered since the observations had been begun. The consequent wetness of the soil was reflected in a great abnormal rise in the ground water. But from August onwards through the winter, and till the beginning of the year, the amount of rain and dew which fell was again far below the average, and the ground water steadily decreased. In the middle of April, 1874, it again began to rise, and then the epidemic of cholera ceased. The abnormal fall of rain in August, 1873, in Munich had the same effect on the cholera there as the south-west monsoons regularly have on the disease in Calcutta. In the relative dryness which follows this excessive wetness the epidemic process is continued as a winter invasion.

Munich and Augsburg are very much alike in situation and in meteorological factors. Both places lie in a direct line not sixty kilometres apart. But that differences in the amount of rainfall may occur is proved by the year of cholera 1873. In Munich, in spite of the excessive fall, the amount for the whole year was hardly up to the average; in Augsburg the excess above the average was 30 per cent. In 1873 the rainfall at Augsburg approached to that of the average at Salzburg. The distribution of the rainfall was different in Augsburg as contrasted with Munich, and the same difference in the history of the cholera holds good of the two towns. Augsburg had an epidemic of cholera in 1854, but none in 1836 or 1873, when only a few isolated cases occurred. That Augsburg in place and time and in individual disposition is susceptible of an epidemic of cholera was seen in the year 1854, when about 3 per cent. of the whole population was destroyed by the malady, whilst Munich lost that year but 2½ per cent. If the appearance of cholera in the two places mentioned differed only in the time required for the transit from one city to another, then the germs of cholera must pass either from Munich to Augsburg or *vice versâ*. In the year 1836 Augsburg remained free from cholera, which infested Munich for six months. At that period no observations on the rainfall were made, but no doubt exists that cases of cholera passed, without isolation or disinfection, from Munich to Augsburg. These facts prove that cholera is a miasmatic disease, and may be wholly independent of human intercourse. For the year 1854 meteorological data are obtainable, and this year had as dry a season in Augsburg as in Munich, whilst at both places cholera prevailed. In the year 1873 the case was different. Then there were in Augsburg regulations for the prevention of the spread of cholera, without which precautions, be it noted, in 1836, Augsburg remained free from the disease. Nevertheless, cholera did not visit Augsburg in 1873, during which period stringent measures of prevention were also in full force at

Digitized by Google

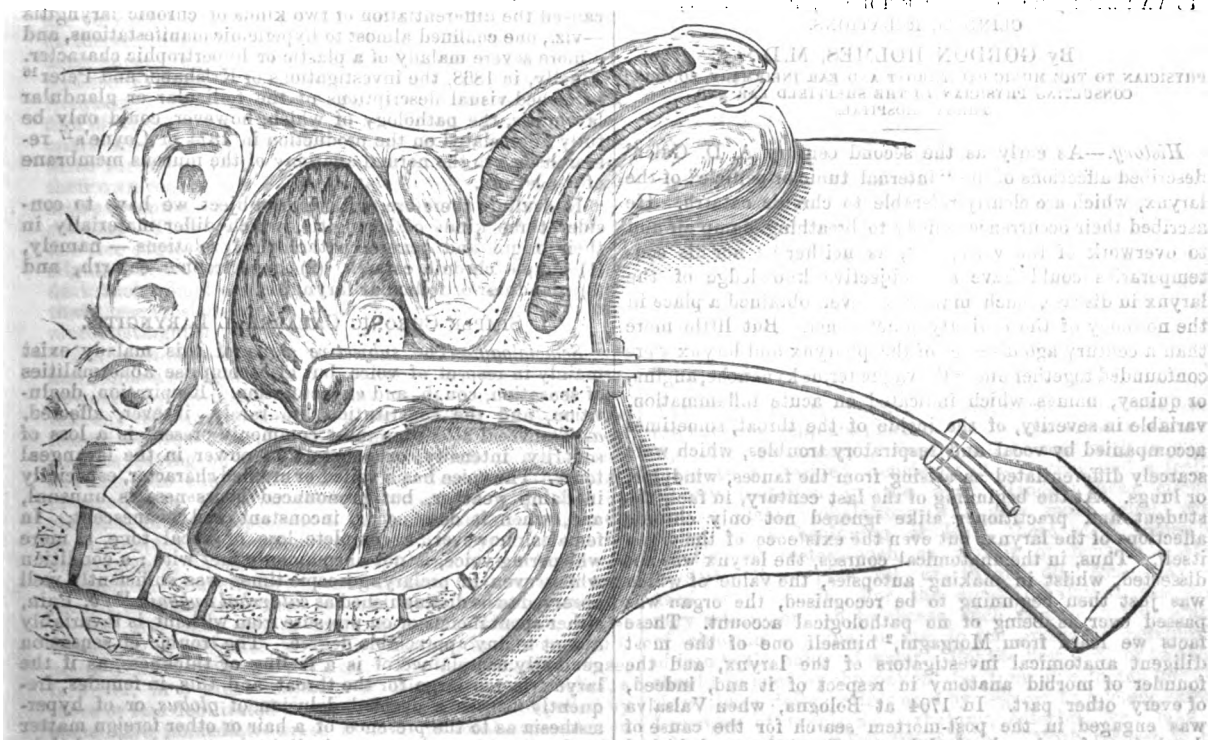
Munich. Such considerations lead to the logical conclusion that what saved Augsburg did not relieve Munich. Further, Munich remained free from visitation in the humid summer of 1866, when cholera prevailed in North Germany; so that no importation of cholera to Munich took place from the seat of war.

(To be continued.)

OBSERVATIONS ON THE

AFTER-TREATMENT OF LITHOTOMY WHERE THE BLADDER IS SACCULATED OR POUCHED.

BY REGINALD HARRISON, F.R.C.S.,
SURGEON TO THE LIVERPOOL ROYAL INFIRMARY.



SACCULATION or pouching of the bladder is not only a frequent cause of stone in adults, but is probably the most serious complication attending its removal. An ill-shapen bladder often renders lithotrity out of the question, whilst it increases both the dangers of lithotomy and the liability to a recurrence of stone. A careful study of the results of lithotomy in adults not only shows them to be unsatisfactory when compared with the immediate risks of the operation, but also seems to point to certain defects in the after-treatment to which it is desirable to direct attention. To remove a calculus out of a pouch or depression in the bladder, and not at the same time to provide against urine lodging in the cavity thus formed for its reception and decomposition, is to incur a risk of cystitis and septicæmia which is by no means an imaginary one. It must be remembered that a saccule has no power of expelling its contents; its walls contain no muscular fibre, and it is entirely dependent on its relation to the general cavity of the bladder for the emptying of whatever it may contain. The small mortality following lithotomy in children and the extraction of stone in women is largely due to the fact that the conditions in both are favourable to the thorough drainage of the bladder.

I have recently been adopting a system of drainage after lithotomy and other cases where the bladder has been opened which has so far proved a great benefit. In the first place, in all instances of stone complicated with a large prostate and with saccules on a depressed floor I have been particularly careful by a sufficient division of the prostate to make a free access to the bladder; this has sometimes necessitated the section of the gland to a greater extent than was requisite for the removal of the calculus.

To provide free drainage after the operation for all depressed portions of the bladder, the following plan has been adopted (it is practically that of the double tube in tracheotomy):—Through an ordinary lithotomy tube open at the end is passed and retained a rubber catheter, or drainage-tube; this adapts itself to the inequalities in the walls of the bladder, and can be made to enter any saccule that may be present. In a recent case, though the ordinary lithotomy tube seemed to be draining efficiently, I had from the general symptoms reason to believe that some urine was retained. On introducing the rubber catheter in the manner described, several ounces of fetid urine escaped, after which the progress of the case was good. By the double tube a constant system of drainage is carried on, so that urine escapes immediately on entering the bladder. The accompanying diagram explains, first, the position the ordinary lithotomy tube should occupy relatively to the divided large prostate (marked *p*); and, secondly, the arrangement by the double tube for securing perfect drainage of a sacculated bladder.

I would remark that to rapidly heal up a bladder which in its mechanical construction has all the elements necessary for the production of calculus is not in my judgment a wise proceeding, so long as anything can be gained by not doing so.

In cases of calculus associated with residual urine and a large prostate, I have had some excellent results in instances where it was deemed desirable to retain the lithotomy tube for considerable periods of time—partly for the purpose of draining and partly with the view of bringing about a permanently improved condition in the outlet from the bladder—namely, cases where the tube has been retained for six, eight, or even ten weeks.

The advantages of the double tube after lithotomy performed under the circumstances mentioned may be summarised as follows:—

1. The prevention of vesical colic and spasm by retention of clots and the plugging of the ordinary tube with blood.

2. The more perfect drainage of the floor of the bladder, however irregular this surface may be.

3. A ready mode of washing out all parts of the bladder without removal of the outer tube. For the latter purpose, one of Tiemann's double current rubber catheters, fitted on to a Higginson's syringe and passed through the ordinary lithotomy tube answers admirably.

4. Increased facilities for keeping the patient dry, by

Digitized by Google

having the inner tube sufficiently long to conduct the urine into a vessel by the patient's bedside; the bed may be kept absolutely dry until the time comes for the removal of the tube altogether. This is a point of great importance, especially in elderly persons, who are liable to bedsores and suffer much from the immediate presence of ammoniacal urine.

The tenesmus and pain at the end of the penis which are sometimes caused, where the prostate is large, by the retention of thick ropy mucus on the floor of the bladder are considerably mitigated by this plan, combined with the free use of some solvent for this secretion. The best solvent for vesical mucus I have yet found is a solution of common salt in warm water, with which the bladder should be washed out, by the double tube as described, as often as necessary. In all cases of this kind the tubes should be retained and drainage employed until the urine shows that it can pass through the bladder without undergoing decomposition in it; so long as there is any sign of the latter, there is a risk of the re-formation of stone. A considerable number of the softer stones are entirely of vesical origin. The prevention of these necessarily brings under consideration the remedying of the causes upon which they depend. These latter are not always difficult to discover.

Liverpool.

CHRONIC CATARRHAL LARYNGITIS:

ITS VARIETIES, WITH THEIR ETIOLOGY, PATHOLOGY, AND CLINICAL RELATIONS.

By GORDON HOLMES, M.D.,

PHYSICIAN TO THE MUNICIPAL THROAT AND EAR INFIRMARY, LONDON; CONSULTING PHYSICIAN TO THE SHEFFIELD EAR AND THROAT HOSPITAL.

History.—As early as the second century A. D. Galen[1] described affections of the "internal tunic or pellicle" of the larynx, which are clearly referable to chronic catarrh. He ascribed their occurrence chiefly to breathing damp air and to overwork of the voice, but, as neither he nor his contemporaries could have any objective knowledge of the larynx in disease, such maladies never obtained a place in the nosology of the ordinary practitioner. But little more than a century ago diseases of the pharynx and larynx were confounded together under the vague terms kynanche, angina, or quinsy, names which indicated an acute inflammation, variable in severity, of the inside of the throat, sometimes accompanied by vocal and respiratory troubles, which were scarcely differentiated as arising from the fauces, windpipe, or lungs. At the beginning of the last century, in fact, the student and practitioner alike ignored not only chronic affections of the larynx, but even the existence of the organ itself. Thus, in the anatomical courses, the larynx was not dissected, whilst in making autopsies, the value of which was just then beginning to be recognised, the organ was passed over as being of no pathological account. These facts we learn from Morgagni,[2] himself one of the most diligent anatomical investigators of the larynx, and the founder of morbid anatomy in respect of it and, indeed, of every other part. In 1704 at Bologna, when Valsalva was engaged in the post-mortem search for the cause of death in a female who had long suffered from phthisical symptoms, nothing morbid being found in the lungs, head, &c., Morgagni, then a student, requested to be allowed to examine the larynx.[3] Destructive ulceration being there discovered sufficient to account for the symptoms, great interest was aroused by the disclosure, and Morgagni by making a point of examining the larynx in his numerous autopsies was able to record a large number of cases which established the importance of the organ as a site for pathological observation. In 1760 Morgagni's great work was published, containing his scattered cases; but not until 1790 was a special treatise devoted to chronic diseases of the larynx. In that year Petit[4] of Montpellier produced a monograph on "laryngeal phthisis," a title which included all chronic laryngeal affections, from the severe forms of catarrh to tuberculosis, syphilis, and cancer, no clear diagnostic line being drawn between these various maladies. During the succeeding thirty years several essays similar to that of Petit were published, with little obvious advance; but the first writer who attempted a separate investigation of maladies of the laryngeal mucous membrane was W. H. Porter[5] of Dublin, in 1824. A few years later Albers of Bonn[6] produced the first comprehensive treatise on diseases of the larynx, and gave a description, remarkably complete for that date, of chronic inflammation of the mucous membrane of the organ. Again, in 1837, Trousseau and Belloc,[7] in their celebrated essay on "Laryngeal Phthisis," pictured the same affection under the name of "simple laryngeal phthisis." In 1846 Horace Green[8] of New York gave the first clinical exposition of the effects of the catarrhal process in the mucous glands and follicles of the air-passages —an affection vaguely known previously as "clergyman's sore-throat"—the first suggestion of the pathology of which was given more than a century previously by Van Swieten[9] of Leyden. In 1853 Rheiner[10] investigated the same disease by morbid anatomy; and again, in 1857, Guéneau de Mussy[11] presented an exhaustive work based almost entirely on clinical observations and inferences. So far, however, the semeiology of chronic catarrhal laryngitis was mainly presumptive, and no wholly trustworthy objective knowledge of the disease existed. Thus, on the introduction of the laryngoscope, observation had a new development to take, and the void was soon filled in after 1858. In this field the researches of Czermak,[12] Türck,[13] Semeleder,[14] and Tobold[15] shortly caused the differentiation of two kinds of chronic laryngitis —viz., one confined almost to hyperæmic manifestations, and a more severe malady of a plastic or hypertrophic character. Finally, in 1868, the investigations of Krishaber and Peter[16] furnished visual descriptions of the follicular or glandular laryngitis, the pathology of which, however, could only be fully appreciated on the production in 1874 of Coyne's[17] researches as to the normal anatomy of the mucous membrane of the larynx.

In dealing, therefore, with this subject we have to consider three kinds of laryngitis, which differ materially in their origin and general pathological relations — namely, (1) simple chronic catarrh, (2) hypertrophic catarrh, and (3) glandular or follicular laryngitis.

I. SIMPLE CHRONIC CATARRHAL LARYNGITIS.

Semeiology.—The *subjective* signs of this malady exist mainly in respect of voice, but also comprise abnormalities of sensation, cough, and expectoration. Respiration, deglutition, and the constitution are rarely, if ever, affected. *a.* The vocal alteration most commonly present is a loss of sonority, intensity, or penetrating power in the laryngeal tones. The voice has a veiled or muffled character, especially in damp weather, but pronounced hoarseness is unusual, and, when it does occur, inconstant and evanescent. In females, however, a complete loss of vocal tone, a mere whispering voice, is not uncommonly met with; a condition which even in prelaryngoscopic times was sufficiently well observed to be distinguished as *catarrhal aphonia.*[18] *b.* Pain, either spontaneous or on pressure from without, is invariably absent to any appreciable degree. The trouble of sensation generally complained of is a feeling of thickness, as if the larynx is too large for the throat, and this, in females, frequently causes a decided delusion of *globus*, or of hyperæsthesia as to the presence of a hair or other foreign matter in the pharynx or larynx. A slight degree of heat and tickling is a usual symptom. *c.* Involuntary cough is a very variable phenomenon, but in a majority of cases it is altogether absent. Should it be present to any marked degree, we must

suspect that the trachea and bronchi are to some extent involved. When the malady is strictly confined to the larynx there is voluntary cough—that is, hacking efforts to clear the throat, which sometimes, if persisted in, induce temporary hyperæmia and irritation of the larynx, &c., with a troublesome fit of involuntary coughing. This occurrence is most likely to take place in the morning. *d.* Expectoration is very scanty, and usually consists of a little viscid mucus, small pellets of which are often brought up in the morning, formed apparently by inspissation of the ordinary secretions during sleep. A more considerable amount of mucus may, however, be discharged after long-continued hacking efforts.

The *objective* phenomena, conformably to the mild nature of the disease, indicate no impressive alterations of the larynx. General congestion of the mucous membrane is seldom well marked, but hyperæmia of the aryepiglottic and ventricular folds on one side is frequently seen, and, perhaps more commonly still, of the posterior or under surface of the epiglottis. Less frequent, but by no means rare, is a slight congestion of the vocal bands, when a red line appears to gleam faintly through the whiteness of their upper surface. Comparatively seldom one or two pink spots resembling slightly elevated granulations may be observed in the same situation. There is also usually a certain dusky or smoked appearance of the whole larynx, the colour of which in any case is more or less patchy or mottled, in contradistinction to the delicate and uniform hue of health. A very striking and common deviation from the normal state of the mucous membrane is the altered quantity, and no doubt quality, of its secretion. Thin flakes and bands of mucus are very often adherent, in a scattered manner, to the surface of the vestibule, having in most cases a blackened appearance, suggesting that they have for some time retained their position exposed to the soiling action of the inspired air. Frequently also the vocal bands are coated with a thick film of viscid, glairy mucus, which, when they are drawn apart after contact, stretches across the glottis in two or three threads till they snap by the force of respiration or their own contractility. Much more rarely than any of the above symptoms do we find patches of shallow ulceration or erosions. These, when they occur, are most conspicuous on the free edges of the vocal bands, as in this position the slightest break in the even outline is well shown up by the dark background of the space beneath. I believe, however, that these erosions are really much more common, not merely more distinguishable, in this situation.

Pathogenesis.—This malady is often of a secondary nature, and forms a sequela to acute catarrh of the larynx. It has, however, by no means invariably such an etiological relationship as some authors have concluded.[19] It may arise insensibly from a variety of slight, but persistent, causes, such as leaving off customary wrappings about the throat, shaving the chin, &c., after long disuse of the habit, inspiration of an atmosphere impregnated with dust or chemical fumes,[20] especially if the mouth be kept constantly open, frequent over-exertion of the voice, by which a series of temporary, though slight, congestions of the organ are occasioned. Its etiology often seems to be intimately connected with the inclement seasons, with frequent exposure to wet and cold, and in many cases the disease, whilst remaining in abeyance during the summer, undergoes a subacute exacerbation every winter. The fundamental cause, however, in a great majority of cases is, in my belief, a more or less debilitated state of health, which is impelled by some more immediate cause to find its local expression in this manner. When secondary it is probably always due in reality to the supplementary action of one or more of the above causes, which resist absolute recovery from the acute attack, and determine the persistency of the chronic affection. This form of chronic catarrhal laryngitis is generally stated to be most frequent in the male sex; but the fact has not been proved by statistics. I have good reason to doubt its truth, as I find it contradicted in my own experience. Thus, out of 70 cases, of which I have a record, 47 were females. As regards age, the malady is essentially one of adult life; 61 of my cases occurred after nineteen and before thirty-eight.

Pathological Anatomy.—There are naturally no special post-mortem researches on which to found a description of the actual structural alterations existing in so mild a disease, but we may safely assume that the morbid process moves in conformity with what has been observed in other mucous membranes. Thus we have increased action of the racemose and other glands, proliferation and shedding of epithelium, their investment being, under the long-continued influence, of imperfect development and comparatively low vitality, whence arises the dull or dusky tint of the surface. The action can, however, never be sufficiently intense to expose the basement membrane, and thus give rise to the excoriations mentioned. For this reason, therefore, these latter must be regarded as a proof of the secondary origin of the malady from acute catarrhal laryngitis, or of the more or less frequent supervention of subacute exacerbations.

Diagnosis.—There is little to be said under this heading, as, under all ordinary circumstances, the malady may be called self-diagnostic. When an apparently similar affection is associated with syphilis or phthisis, the concomitant symptoms will direct attention to the fact, but often time alone can determine whether the disease is a simple one or the introduction to destructive ulceration in the larynx.

Prognosis.—In uncomplicated cases this is entirely favourable as regards progress towards any serious lesion, but with respect to absolute cure we can seldom anticipate that the malady will terminate without some weeks, or even months, of more or less assiduous treatment. The longer the disease has been established, the more probability, of course, that its cure will be protracted. In the most obstinate cases, however, time unaided—that is, a period of months or perhaps years—will almost invariably bring about a gradual amelioration.

Treatment.—Constitutional as well as local measures will generally be required. (*a*) When we observe clearly or suspect a state of cachexia, in which the tendency is towards anæmia and debility, we must give tonics, especially iron and cod-liver oil, prescribing at the same time a well-regulated and nutritious diet, with a small amount of wine or other alcoholic stimulant. In the presence of corpulence or plethora, quinine should be administered and a light unstimulating diet, with perhaps a course of saline and laxative mineral waters at a suitable health resort, should be counselled. Change of air and scene will often be necessary, and always advisable. (*b*) Very few cases will get well without local treatment, and those only which are of recent date. The means to be adopted are the application of astringents directly to the larynx by inhalation, lozenges, and the laryngeal brush. In most of these cases I have found cold spray inhalations more effective than those in which steam is the vehicle for the medicinal substance. As the mucous membrane is usually in a markedly hygroscopic condition, it swells in the presence of moist and warm vapour, and hence the patients complain more of the foreign sense of thickening, &c. Instances, however, will be met with in which there is a decided deficiency of secretion and a feeling of dry irritation in the part. Under these circumstances steam inhalations will give most relief, especially for a beginning at least, those of a somewhat sedative character, such as vapour of benzoin. After a little time pine oil or thyme oil, &c., may be used with benefit. For the spray inhalation the ordinary astringents can be chosen, such as two to four grains of chloride of zinc, or six to ten grains of perchloride of iron to the ounce of water. For the first week or two they should be used by the patient for from five to ten minutes three times daily; afterwards by degrees to a lesser extent. Lozenges of tannic acid, rhatany, catechu, &c., may be taken, one, four or five times daily. With respect to the applications with the brush, solutions of the same salts as contained in the spray inhalation, but of much greater strength, may be employed. Perchlorides of iron (60 to 120 grains to the ounce of water) has generally proved most satisfactory in my hands. It should be applied daily for the first week or ten days, and often, indeed, twice daily, with decided advantage. But if the cure is at all protracted, the application will have to be varied from time to time according as toleration of the special action of any one drug is established.

(To be continued.)

A REMARKABLE CASE OF A JUVENILE EARTH-EATER.

BY CLEMENT DUKES, M.D., B.S., M.R.C.P. LOND.,
PHYSICIAN TO RUGBY SCHOOL, AND TO THE HOSPITAL OF ST. CROSS, RUGBY.

THE following case seems to me to be of sufficient interest for publication.

P. B——, aged five years, residing quite in the country, was brought to the Rugby Hospital on December 18th, 1883, by her mother, who carried with her in a bottle a characteristic specimen of the common round worm, ascaris lumbricoides. The mother gave the following history: Two years ago the child did not seem well, and after a day or two she became sick, and threw up a large round worm. The mother then gave her a dose of castor oil, and she passed by the bowel three more. A week after this the mother noticed that the child ate the soil in the garden, or that by the side of the road. To stop this vicious habit the child was kept indoors and scolded and whipped, but without effect; for whenever the mother was engaged in her household duties the child would immediately run out and eat the dirt. She always said, when reprimanded, that she ate the earth to relieve the gnawing pain in her stomach. So urgent was the demand for this soil-eating that the child would, if she could not get earth, eat sand, would pick the mortar out of the walls between the bricks, and she would even store a supply in her pocket to eat at her leisure, when she could not get out to obtain it. She has continued to eat the soil, in spite of continual punishments, until the time of her entrance into the hospital on February 12th, 1884, when she ceased, as far as could be ascertained, to eat the soil. The mother states that she would put the earth in her mouth, suck it, and then swallow it. She further states that during the two years of earth-eating she has brought up or passed by the bowel about a hundred large round worms. From the number I have seen myself, and from the respectability of the mother, I fully believe this statement. While in hospital she passed many, but under santonin they failed to come away; and after being without any for a month, and having become fat and strong, I discharged her on April 10th, 1884, as I thought cured. But on May 2nd her mother brought her back, she having passed another worm, but she had not again taken to eating earth. During the child's stay in hospital her perverted taste had apparently been cured. I readmitted her, when she soon passed a worm, and vomited another; but under two-grain doses of santonin, three times a day, which she took for several weeks without physiological effects, she gradually ceased passing any more, and regained her health, strength, and good looks.

Cobbold says, round worms are rare in British practice, and usually only one occurs: this is my experience. But he also records that Mr. de Morgan had a patient at the Middlesex Hospital from whom thirty-seven were expelled. After the little patient's return to the hospital, I examined the well water microscopically, but failed to find any eggs of the round worm. On Oct. 4th I again saw the child by accident. She was looking well, and had not been troubled with more worms, nor had she again taken to earth-eating.

Rugby.

IRRITATION OF THE SKIN FOLLOWING THE APPLICATION OF VASELINE AS A SURGICAL DRESSING.

BY A. W. MAYO ROBSON, F.R.C.S.,
SURGEON TO THE LEEDS GENERAL INFIRMARY.

ON several occasions within the last two years I have, both in private and in hospital practice, noticed that severe inflammation of the skin has been set up by the application of vaseline as an ointment, which has subsided on applying some other simple dressing. The following examples will serve as illustrations:—

CASE 1.—Mrs. S—— attended as an out-patient at the Leeds Infirmary for simple ulcer of the leg, for which a Martin's bandage was ordered to be worn during the day, and vaseline to be applied at night. On her next visit she complained of severe burning in the leg, which was covered with eczema for two inches round the ulcer. The patient was advised to rest and to stop applying the bandage, but to continue the vaseline. On her next visit the inflammation had extended over the whole leg. I now thought it might be due to the vaseline, and ordered zinc ointment, which rapidly cured the irritation and enabled the bandage to be worn again, which soon cured the ulcer.

CASE 2.—W. C., aged eight, was brought to my rooms suffering from ophthalmia tarsi, for which I ordered yellow oxide of mercury with vaseline. On the next visit the eyelids were swollen and œdematous, so that the eyeballs could not be seen. I ordered the lids to be washed and simple olive oil to be applied. Two days afterwards, the swelling having subsided, I again ordered yellow oxide of mercury and lard as an ointment, and soon cured the case.

CASE 3.—A. Q——, aged four, was brought to my rooms suffering from a wound of the forehead, which was strapped but did not heal by first intention. After a week vaseline was applied; within twelve hours the forehead was covered with small blisters and the skin became brawny. On discontinuing the ointment and applying some other simple dressing the irritation soon subsided.

CASE 4.—A. B—— was admitted under my care into the infirmary suffering from scalds of the legs. Vaseline was applied and produced severe irritation, which subsided on its discontinuance.

CASE 5.—C. B——, aged seventeen, was admitted into the infirmary suffering from a smashed leg, for which I performed primary amputation. Near the termination of the case, the granulations being feeble, red lotion was used and vaseline was applied on lint over the lotion to prevent evaporation. It did very well for some time and was healing rapidly until one morning on my ward visit I found the sore inflamed and the adjoining skin œdematous. I could find nothing to account for this, as the same dressing was being used that had been employed for at least a fortnight, until the nurse told me she was using some fresh vaseline, which had a greenish colour but was said to be very pure. On discontinuing this the inflammation subsided and the sore again began to heal.

I need not enumerate any more cases, but I have no doubt other surgeons will have had the same experience. In the above examples I suppose the irritation may have been due to some impurity in the vaseline, as, if pure, it should be a perfectly bland preparation. But it may be that some skins present the same idiosyncrasy to preparations of vaseline as others do to any application of tar, and this seems to me more likely, since whilst the same vaseline was used in many other cases without producing irritation, in these exceptional cases severe dermatitis was set up.

Leeds.

TUMOURS OF THE TRACHEA.

BY HENRY CRUTCHLEY, M.D., L.R.C.P. LOND.
WITH NOTES BY DR. MORELL MACKENZIE.

J. B——, aged forty-nine, married, farm labourer, has had a family of twelve children, ten of whom are now living. His mother died of consumption, and she suffered from scrofulous glands. The patient is a steady, sober man, has enjoyed good health, and has never had syphilis. His present ailment came on gradually about two years ago, when he first perceived a "wheezing and whistling" in his throat upon exertion. His general health continued good, and he followed his employment without inconvenience, except when hurried, till twelve months ago, when he felt that there was "an obstruction in his throat," which kept gradually getting worse, until he had to give up his work, a month before last Christmas. He has not had much cough and very little expectoration, but felt roughness and tickling in his throat. He had no pain or difficulty of swallowing. When I first saw him, though somewhat thin, his complexion looked healthy, and there was no lividity. He had an occasional rough, short cough; no hoarseness. His voice was rather high pitched, and had somewhat of a falsetto character. The larynx did not rise or fall during respiration; there was inspiratory and expiratory stridor, the former scarcely more

Digitized by Google

marked than the latter. On laryngoscopic examination the glottis was widely open, the cartilages of the arytenoids and of Santorini showing scarcely any adduction during expiration. The vocal cords came into view only on phonation. The lumen of the trachea was seen to be occupied by a large reddish tumour, and appearing to grow from the side of the tube was a smaller one with a long pedicle, the smaller tumour rising and falling in the respiratory wave with a distinct flapping motion. The diagnosis was stenosis of trachea, caused by a benign outgrowth, probably multiple papilloma. The patient was sent to Dr. Morell Mackenzie for the purpose of having it removed. A large tracheotomy low down was performed with this object on March 3rd. The tumour was then seen to be a vascular growth, the upper limits reaching to within a short distance of the larynx; the whole tumour, about two inches in length, not being visible, as it extended further towards the bronchi. The patient made a capital recovery, talks with ease, and has worked all the summer in the harvest.

Notes by Dr. MACKENZIE.—On opening the trachea the growth was seen to be attached to the whole of the inner surface of the cricoid cartilage, and to extend down the right and posterior walls of the trachea for about an inch and a half, gradually becoming less raised above the surface until it passed imperceptibly into the mucous membrane. A microscopic examination showed the growth to consist of highly vascular connective tissue. It was found impossible to remove it.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem cetalis pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

GUY'S HOSPITAL.

SCALP WOUND, FOLLOWED BY BRAIN SYMPTOMS; TREPHINING ON THE THIRTEENTH DAY; TEMPORARY RELIEF; DEATH ON THE TWENTY-FOURTH DAY AFTER THE ACCIDENT; SUPPURATION OF CEREBRAL MENINGES; BRONCHO-PNEUMONIA.

(Under the care of Mr. BRYANT.)

WE are indebted for the following notes to Mr. Hilbers.

Thomas S——, aged four, was admitted into Lydia ward on Oct. 9th, 1882. Five days before admission the child fell into a hole about three feet deep. He got out himself, and beyond a scalp wound seemed none the worse for the fall, for he ate and played about as usual. On the following day he became drowsy and was sick. His mother took him to the hospital, but refused to allow him to remain. The scalp wound was dressed. As the child continued in the drowsy state, and was sick, his father took him to the hospital on the 9th, and left him.

On admission there was a scalp wound over the right eye. The wound gaped a good deal, and the bone was exposed. Temperature 103°. The child looked very ill, and was very drowsy. A dose of castor oil was given, and the child was put upon limited milk diet.

On the 10th the child was still very drowsy. The wound and parts about were a good deal puffed up. The wound was dressed with terebene and oil. Morning temperature 101·4°; evening, 102°.

Next day there was a slight discharge from the wound, which was still puffy. Temperature 101·7°; pulse 102.

On the 12th there was still some discharge. The patient complained when a spot just below and to the outer side of the eye was pressed. Temperature 101·8°.

On the 13th the wound looked better and there was less discharge from it. Apparently an abscess was forming on the outer side of the outer angle of the right eye. Temperature 99° F. The diet consisted of bread and butter and milk. Poultices were applied to the abscess.

On the 16th the abscess seemed to be diminishing in size. The poultices were discontinued. The wound in the scalp discharged very little, and there was no bare bone to be seen. Maximum temperature 103°.

On the 17th (thirteenth day), early in the morning, the patient was seized with convulsions, and the fit lasted an hour. At 8.30 A.M. he had a spasmodic contraction of the left side (the wound was on the right side). The mouth and eyes were twitching towards the left side, and there were continuous spasms of the left arm and leg. The left pupil was slightly contracted. Temperature 102·4°. Heart beating tumultuously, radial pulse uncountable. The patient was given a warm bath and ice was applied to the head. The convulsions lasted on and off until 2.30 P.M., when the operation was done. At that time the left side was completely paralysed. At 2.45 P.M. an incision was made transversely through the wound, when a slight depression was discovered. The bone was bloodless. The patient was then trephined with the second smallest trephine, and the bone removed with forceps. There was no proof discernible of the inner table having been splintered, but upon one of the pieces of bone was some suggestion of it. The bone around was bloodless. The wound was dressed with terebene and bandaged. A Leiter's coil was applied to the head. At 4.45 (two hours later) the child was sensible and appeared better. At 8 P.M. he could move his left arm and leg, but not so freely as his right. The axis of the eye was now only directed upwards at intervals.

Next day the child was conscious. The wound was dressed. No pulsation of the brain was apparent, and the brain slightly protruded into the opening in the bone. He was delirious during the night, but in the morning was conscious, and the pupils were equal. Temperature 102°.

During the night of the 20th the child got out of bed and walked to the fireplace. Maximum temperature 103°.

On the 21st he was better. Temperature 99·9°; pulse regular. In the afternoon the temperature rose to 104·2° F. Ordered to be sponged with ice water.

On the 22nd the bowels were found to have been freely opened during the night. He wandered in his sleep. Face pasty and white. The wound looked well, and the trephined place was covered with granulations. Morning temperature 102·6°; evening, 103·6°.

On the morning of the 23rd he was quite sensible. Skin dry and hot; lips parched and dry; hands hot; tongue tremulous and covered with a little white fur; the papillæ were swollen and red; there was some twitching of the left eye and mouth. Wound looked healthy. Bowels not opened since yesterday. Temperature 104° F.

On the 24th, at 2 A.M., he had a fit which lasted five minutes. He had not been sick, and he did not perspire. He seemed very drowsy, and cried out at times as if in pain. Temperature 103·8°. Bowels had not acted.

On the 25th he was very pale; did not care for his food. The legs were drawn up, the abdomen not retracted. Morning temperature 103°; evening, 102·2°.

On the 26th the bowels acted during the night. The patient was in a semi-comatose condition; he cried out when his head was touched. Optic axis divergent; pupils, and particularly the right, reacted badly to light. Skin dry and hot; breathing fair and rather rapid. Morning temperature 103·6°; evening, 102·2°.

On the 27th he had two fits during the morning, each lasting only a few minutes. Beads of perspiration formed on the forehead after the fits. The right arm and leg were spasmodically contracted; abdomen fall, but not retracted; tongue thickly coated. Evening temperature 104·4°.

On the 28th the eyes were turned upwards; pupils fairly dilated; quite insensible. The patient unconscious; colour rather dusky. There was twitching of the arm and leg. Maximum temperature, 104·2°. At 2.45 P.M. he had another fit, lasting about twenty minutes. Temperature 103·1°. Pulse uncountable, weak, and quick. Difficulty in breathing; nostrils widely dilated. Eyes and face white and waxen. Later, the left leg began to twitch. Great perspiration on the body, but not of the face. At the end of the fit the face became slightly flushed, but this quickly passed away. The eyes were turned upwards. Pulse quick and feeble, respiration jerky. Had two more fits during the evening.

On the 29th he had two fits, lasting a long time. At 3.30 A.M. the temperature was 105°. He never seemed to recover from the first fit, and died at 5.30 P.M. Breathing rapid and laboured. Moist sounds in throat. Right pupil larger than left. Skin moist, pale, and slightly dusky.

Necropsy.—On the right frontal eminence, or rather above it, there was an oval wound with bare bone at the bottom, and in its centre a small trephine aperture. The bone around this aperture was yellow and evidently infiltrated with pus. On

Digitized by Google

the inner table there was a zone of vascularisation, and a little lymph some slight way off the trephine wound, the edges of the latter being rather spiculated but not depressed. The outer surface of the dura mater had a layer of vascular granulations upon it corresponding to the trephine wound, and on examination the under surface of the membrane on the right side was seen to be exceedingly vascular and covered more or less all over by a layer of granulation tissue. The hinder part was distinctly more vascular than the front part, which might be explained by the gravitation of septic material from the front of the arachnoid cavity; The greater part of the pia mater on both hemispheres was coated with a continuous layer of greenish-yellow lymph. There was but little difference between the two sides in this respect, and at the base also there was a considerable quantity and over the upper surface of the cerebellum. The interior of the brain was quite healthy and there was no evidence of any injury to the brain from the fall. It seemed probable that the injury to the bone was the primary trouble, that this led to suppuration by extension through the membranes, and to the fatal result. There was a good deal of broncho-pneumonia on the left side. The other viscera were healthy.

LIVERPOOL INFIRMARY FOR CHILDREN.

ACUTE MANIA IN A CHILD OF FIVE YEARS; RECOVERY; REMARKS.

(Under the care of Mr. E. HYLA GREVES.)

FOR the notes of the following interesting case we are indebted to Mr. Harding H. Tomkins, M.R.C.S.

Agnes K——, aged five years, was admitted on June 26th, 1884. She had had no acute disease of fever, but had always been somewhat delicate and nervous. About two months before she began to lose her appetite, complaining of pain in her stomach, and suffering from constipation; she lost flesh, and became languid and inclined to sit about instead of playing. Timidity increased, and on one occasion she was terrified for some hours by an earwig having run over her. On June 24th, having gone to bed, the light of a candle from a house opposite shone across her bed, and she became wildly excited and could not be pacified; she remained so until admission. The child's mother is a healthy woman aged thirty-eight, but of somewhat nervous temperament. The father died at the age of fifty, was a ship's engineer, had been a hard drinker all his life, the wife never remembering him sober a single day when on shore during twelve years of married life; he had delirium tremens more than once, and "fever" when abroad; he finally died a few weeks ago from consumption. The family consisted of seven children (no miscarriages); three of these died young of measles and other acute diseases; a fourth, the patient's companion sister, died a few weeks ago from obstruction of the bowels; the eldest, a girl of eleven years, is living, as also are two others, all three being highly nervous, and one rickety. The patient was born at full time after a precipitate but natural labour. No history of insanity, consumption, epilepsy, &c., on either side of the family. The mother was not nervous till after marriage. Grandparents healthy, but maternal grandparents both died young. No consanguineous marriage of parents or grandparents.

On admission the child was very sparely nourished. Height 3 ft. 4 in.; weight 33 lb.; skin dry and harsh, even scaly on abdomen in patches, with a purpuric rash on both legs, especially near the ankles; temperature about normal; cheeks flushed; tongue slightly furred, dry; lips dry and cracking; slight sordes present. Expression indicated intense mental action, wild one moment, terrified the next; eyes wild looking, brows knit, hands clenched; movements incessant, leaping out of bed every moment, clutching wildly at those restraining her, looking quickly in all directions, as if seeing or expecting to see some terrible object, constantly crying in a piteous tone, "Were you there?" "Was mother there?" "Who was it?" Lying down one minute, then springing up wildly with dilated pupils and knit brows, shrieking; again, in a mournful tone addressing me as "father," and saying, "Were you there then?"

June 27th.—Having been put in a separate room on admission, she continued very wild, exhibiting almost incessant motion, only controlled at all by the nurse taking her in her arms; and even then frequently starting up, talking wildly, and struggling. Ten grains of bromide of potassium and five of chloral hydrate were administered at 4 P.M., 6 P.M., and 8 P.M. on the 26th without effect, the patient only sleeping twenty minutes. At 9.30 P.M. she went to sleep, waking up in an hour as wild as ever; slept again from 11 P.M. till 2 A.M. this morning. During her ramblings, which were characterised by the disconnectedness and multiplicity of topics so usual in mania, she talked of the "School Board," of a "rag and bone man," and "a bucket of water," and said she was "locked into a room," and some one had pulled the blind down and she could not get out; she looked into the corner of the room in evident terror at some unseen person, and said in a mysterious tone, "Is she white?" "Is she painted white?" and then, the relief nurse coming on duty, she shrieked in a paroxysm of terror, stamping her feet and clutching at the nurse beside her while she sprang up in bed. "Oh! cover me up; cover my face; she *is* coming." The distressed and contracted expression did not leave her even in sleep. Her attention, however, was arrested on several occasions by the nurse, who was able to make her repeat verses (which the child appeared to know) after her. The bromide and chloral were given at midnight (26th), at 9 A.M., 12 noon, 3 P.M., and 6 P.M. (27th). She slept one hour in the morning and another in the afternoon. She took her food well, consisting of mincemeat, soup, Brand's beef essence, maltine and milk, besides bread-and-butter, &c. About 8 P.M. she talked rationally for half an hour or so, and then became maniacal again. Temperature 101° F. at 5 P.M.; 102·6° at midnight, accompanied by diaphoresis. Pulse rapid and small. She passed no urine from 2.30 P.M. on the 26th until noon on the 27th, when her bowels were opened slightly.

28th.—Slept nine hours between 9 P.M. on the 27th and 8 A.M. on the 28th, waking frequently, and still manifesting the same mental condition; she also slept two hours and a half in the middle of the day, not having had any medicine since 6 P.M. on the 27th. During the day she became quieter for a short time, and allowed the nurse to leave the room; up to this time the slightest movement from her bedside on the part of the nurse had caused a paroxysm of terror; she, however, became maniacal again and exhibited delusions of sight and hearing, sitting up suddenly in bed and staring wildly at imaginary objects and straining to listen to some imaginary voice. Temperature 100° at 4 A.M.; 98° at 9 P.M. Bowels open in early morning and at 4 P.M. Urine could not be saved. Vomited after her breakfast.

29th.—The patient slept about four hours and a half, from 6.30 P.M. on the 28th to 4 A.M. on the 29th, waking frequently and exhibiting various delusions, imagining she saw and felt rats running over her legs and people coming to her, and that a picture of Garibaldi on the wall was a policeman. She continually begged not to be left alone, not to be locked up or thrown out of window, and thought her medicine was poison to kill her; she thought her mother was dead, and begged not to have her legs cut off. At 5 A.M., as she had been so wild all night, she had a solution of one-thirtieth of a grain of hyoscyamine by mouth. She soon became flushed and sweated a little, her pupils becoming dilated. She slept for one hour, her temperature being 101° on waking, and though awake for two hours afterwards she remained quiet. She had two hours and three-quarters sleep during the day. She seemed somewhat depressed, her expression and delusions more allied to melancholy; the contraction of facial muscles, though continuous, was altered in character, giving a sad expression. She still addressed the surgeon as "father," though saying her father was dead and she had never seen him, she having seen him often during two or three months before his death. She got up in the afternoon, but became so wild and unmanageable that she was put to bed and had one-thirtieth of a grain of hyoscyamine at 9.30 P.M. The temperature then rose to 100°; she became flushed, pupils dilated, pulse increased in rapidity, and she became quiet very shortly, dozing for a while and going to sleep at 10.30 P.M. Before going to sleep she fancied she saw the medical officer fighting with her mother, whom he killed. Her conversation throughout the day consisted in entreaties that she might not be killed or beaten, &c., and she even stopped when being coaxed to eat, in the middle of her dinner, to say, "You won't beat me, then; but will you beat me? you won't be angry then?" Bowels moved twice; urine, sp. gr. 1020, acid, clear, no albumen or other abnormality.

30th.—Slept five hours and three-quarters after hyoscyamine, and though waking at intervals she was quieter, and slept once for two hours and a half without waking. She

Digitized by Google

got up at 10 A.M., and remained up till 7 P.M.; her attention more easily attracted by various amusements, her behaviour calmer and altogether improved, though she manifested an utter want of memory except for such things as nursery rhymes, some of which she repeated with help. Her mother visited her. On first seeing her the child said "Mother!" in a mechanical way, but when the mother sat down and spoke to her she turned away and said, "Where is mother?—is she dead?" and when her mother was pointed out to her she only said, in a vacant way, "Is she there?" and in the next moment went on rambling regardless of all her mother said to attract her. Temperature, morning, 98°; 10 30 P.M., 100°. Bowels open three times. She had one-thirtieth of a grain of hyoscyamine at 8 P.M. Appetite still good; tongue clean.

July 3rd.—Slept six hours and a half between 8.45 P.M. on June 30th and 9.45 A.M. on July 1st, sleeping only about fifty minutes at a time except from 2 A.M. till 4 A.M. She showed an utter want of memory for names, but was able to roll bandages when shown how to do so, and she amused herself quietly walking after the nurse about the ward, and going out into the garden under the care of other children, yet showing fear of punishment &c. as hitherto. On July 1st she slept five hours and forty minutes, having had one-thirtieth of a grain of hyoscyamine at 10.30 P.M, which produced the desired effect in half an hour, but she only slept for about forty minutes at a time until 7.15 A.M. on the 2nd, when she fell asleep for two hours and a quarter. She then woke, and was very wild, but after sleeping for an hour at midday she became quiet and lost her usual distressed expression. In the evening of the 2nd she went to sleep for the first time without medicine, and slept from 7.15 to 9 30 P.M., but as she did not seem inclined to sleep again one-thirtieth of a grain of hyoscyamine was repeated at 10 P.M. This had no effect till 12 P.M. beyond the usual dilatation of the pupils; after this she slept for an hour, and then woke up full of delusions and hallucinations—e.g., she thought she saw her dead father and sister, and other horrible sights, which made her scream with terror whenever she woke. She also thought her leg was cut off and she was bleeding to death, and that her arm was crushed and broken. One-thirtieth of a grain of hyoscyamine was again given at 2 A.M. on the 3rd, after which she slept from 2.15 to 5.30 A.M., waking frequently for a moment, and quietly going to sleep again. During the day she slept for an hour, and amused herself all day watching the other patients, and following the nurse in the general ward.

6th.—She had hyoscyamine as usual at 6 P.M. on July 3rd, but at 2 A.M. on the 4th it was repeated, as she had only slept three hours and a half; she then slept for another three hours and a half. On the 4th she did not sleep for two hours and a half after her medicine, and during the night was very wild. Instead of the second dose she had bromide of potassium and chloral at 10 P.M. as before, and slept from 11 P.M. till 2 A.M. on the 5th, after which time it became necessary to move her from the general ward to a separate room. During the day of the 5th she was at times sullen and morose, at others vicious towards the children and angry when they tried to amuse her. On 5th, at 5 30 P.M., she had hyoscyamine again, and slept from 6 P.M. till 3 A.M. on the 6th, when she became restless and had a second dose, as she had been so bad the night before. This dose had no effect. Bowels regular. Appetite good.

7th.—Having remained quiet, though deluded, throughout the 6th, she was put to bed and slept from 7.45 P.M. till 5 A.M. on the 7th, not having taken any medicine, and on waking exhibited for the first time some signs of returning memory, as she remembered a child's name and one or two other things. She was, however, passionate and wilful all day, a great contrast to her previous purposeless rambling.

9th.—Slept from 8.45 P.M. on July 7th to 5 A.M. on the 8th without hyoscyamine, but on waking was very wild and wilful, tearing her ribbons off, pulling her hair down and manifesting other destructive tendencies, and picking her head till it bled. Towards evening (8th) when quiet she asked if she was "absent," for a doctor had said she was; she helped to get the supper and asked what the patients were to have. She then asked to go to bed, soon falling asleep; she slept for three hours, waking at 10 P.M., remained awake for an hour, and then slept for three hours more. At 4 A.M. she became so noisy and violent, screaming, &c., that the medical officer was obliged to go to her. The moment he entered the room she lay down in bed pouting, looking ashamed of herself, but immediately he left her she began again. One-thirtieth of a grain of hyoscyamine was given again by mouth, which made her sleep from 4 30 A.M. to 6 A.M. (9th). Throughout the day she bit and scratched those tending her and her expression was quite malignant, but her memory and understanding improved decidedly. She went to bed not having any medicine.

10th.—Having slept all night (nine hours) she became very excited, pulled the nurse's hair, and worked herself into a paroxysm of fury, sitting up in bed with clenched fists and half-closed jaws, the saliva bubbling and frothing between her teeth as she shrieked with passion. She had several of these attacks during the day, and bit one nurse till she drew blood. By 5 P.M. she was so bad that no one could quiet her, and she was found worrying a nurse's leather waistband like an angry dog. One-twentieth of a grain of hyoscyamin by mouth was repeated. This had little effect till 7.15 P.M., when she was soothed to sleep, after having bitten her mother, who had come to arrange about removing her to the union. On waking at 9.30 P.M. she was worse than ever, hissing through her teeth in an angry tone, and with semi-tragic style, "I'll bite you! I'll kill you!" at the same time tearing at her hair and at those who approached her. She was put in a room where she could be watched, and at 10 P.M. one-fortieth of a grain of hyoscyamine was given hypodermically. In eight minutes she ceased to scream, although previously she had done so with every expiration; in ten minutes she gaped and looked about her in a sleepy way with dilated and immovable pupils, then sank down on the bed and fell asleep.

11th.—She slept till 8 A.M., only waking up partly on two occasions. On waking she was much improved, though sullen and occasionally vicious. She was taken to Walton Union, having had one slight outbreak at home in the afternoon. Weight when discharged 35 lb., being an increase of 3 lb. All her bodily functions were well performed during her residence at the infirmary.

On the 16th Mr. Tomkins visited her. She was absolutely silent and appeared not to recollect him at all, she clung to the last person she was with and appeared frightened to trust herself to anyone else. Her appetite remained good, she slept well and had had no further outbreak, though her facial expression was anything but natural. She was reported on one occasion to have thought men were hitting her on the head in the night.

On August 16th she was again visited, and found to be greatly improved mentally and physically. Her skin was fairly filled out and bronzed with exposure to the sun, her flesh being firm and healthy. She ran and raced in the airing court, highly pleased with herself, and danced when told to do so, but she had no recollection of anything previous to her residence in the union, nor could she remember the name of the nurse she was constantly speaking of and calling to when at the infirmary. She could, however, repeat several things she had learnt. Her head, which hitherto it had been impossible to measure, was 18½ in. in circumference, 13⅝ in. from the nasal process of the frontal bone to the occipital protuberance, and 12¼ in. from the tip of one mastoid process to the opposite one. She had gained another 3 lb. in weight. She appeared free from delusion.

On September 17th Mr. Tomkins visited her and found she had been in the school-ward for some time, was reported as a "sharp child," and was progressing well with her lessons, being able to read simple sentences and spell cat, dog, &c. She recognised Mr. Tomkins at once, called him by his name, saying she had seen him "in the same house where nurse Nelly was" (the nurse whose name she had not hitherto remembered). To all appearance she seemed to have entirely recovered and the resident medical officer had discharged her.

Remarks.—The foregoing case is interesting on account of the extreme youth of the patient, the slight hereditary tendency, the violence of the attack, and the speedy recovery following treatment, which was commenced within about thirty-six hours from the onset of the actual attack. The temperature was also considerably higher than that usually registered in acute mania, and the almost abrupt termination of the violent symptoms following (for a child) a large dose of hyoscyamine, suggests the possibility of that drug having cut short the attack, as it is reported to have done in several cases in the adult. Amongst the predisposing causes in this case it is interesting to consider not only the fact of the father's inveterate drunkenness, but the effect that this had

Digitized by Google

upon the mother, and upon the early life of the patient; for it will be noticed that the mother herself had become highly nervous before the birth of the child, and during her conception and pregnancy had been subject to mental worry and frights caused by his behaviour, all of which might strengthen the neurotic tendency of the child. Then the child, naturally of a nervous temperament, throughout its early life was frequently subject to cruel treatment and mental trouble, and it is generally recognised that the recovery of all cases of acute mania is directly proportionate to the length of time which elapses before treatment is adopted, and this seems partly to explain the fact that although the patient combined several of the symptoms which usually determine a bad prognosis—e.g., her extreme youth,[1] the hallucinations of hearing, &c.,—yet the recovery took place in less than two months. The height of the temperature may, perhaps, be explained by the fact that the temperature in young children varies considerably without apparent adequate cause. It is also interesting to note that she took eighty grains of bromide of potassium and forty grains of chloral in twenty-six hours before much effect was produced, and it required half that quantity to effect three hours' sleep; also the fierceness of the excitement was in no way lessened by the medicine, whereas after the hyoscyamine, although the amount of sleep was not perceptibly greater at first, the whole tone of the delusions and general appearance of the patient altered in character, while the discontinuance of the drug for three days was marked by a corresponding increase in the intensity of the symptoms. The immediate effect of the hypodermic injection when the symptoms were at their height is also interesting, more especially as the ten hours' sleep thus produced was not followed by any relapse into excitement throughout the period of convalescence, although on two occasions she had slept for nine hours in succession without medicine, the symptoms only gaining in strength and intensity on waking. The effect of the hyoscyamine appeared to be less marked after the first few doses, and it will be noticed that the delusions and hallucinations existed on admission, and before any kind of medicine had been administered. The last dose administered was equivalent to about half a grain in the adult, for she had one-twentieth by the mouth and one-fortieth hypodermically, being in all equivalent to one-tenth, that is, equivalent to four-tenths in the adult, as the proportionate dose for her would be one-fourth the dose for an adult. Now half a grain given in the adult has several times appeared to have cut short the attack, and so it seems to have done in this instance.

PATHOLOGICAL SOCIETY OF LONDON.

Coarctation of Aorta. — Caseous Pneumonia simulating Empyema. — Tubular Epithelioma. — Cardiac Aneurysm.—Lympho-sarcoma of Liver.—Intestinal Ulceration in Paraplegia.

AN ordinary meeting of this Society was held on Tuesday last, Mr. J. Whitaker Hulke, F.R.S., President, in the chair.

DR. HALE WHITE showed an example of the remarkable condition described as Obliteration of the Thoracic Aorta. The specimen was taken from a male subject aged forty-six, which during life had been diagnosed by the patient's doctor as a case of heart disease. The physical signs were a systolic bruit and some œdema of the lower extremities. At the post-mortem examination the aorta was found to be so constricted at the point where the ductus arteriosus joins it, that it would only just admit an ordinary probe. The ductus arteriosus had completely disappeared. The aorta between the left subclavian artery and the constriction was so small that the subclavian artery appeared to be the direct continuation of it. The thoracic and abdominal aorta were very small. The collateral circulation was thus carried on:—The superior intercostals were very large and convoluted, and anastomosed with the first aortic intercostals, which were also very large; the posterior scapular arteries, both of which came from the third part of the subsubclavian artery, divided on the back of the upper border of the scapula into two branches, which reuniting formed a circle on the back of that bone; from these posterior scapular arteries branches of great size were given off, which anastomosed with the second, third, and fourth intercostal arteries close to the spinal column; the right subscapular artery was extremely large and tortuous and divided into two branches, both of which joined the intercostal artery in the ninth space; the left subscapular artery joined the arteries of the ninth, tenth, and eleventh intercostal spaces; the internal mammary arteries anastomosed with the aortic intercostals—the phrenic arteries, and by their superior epigastric branches, which were very large and tortuous, with the deep epigastric arteries; the right superior epigastric gave a large branch, which descended in the suspensory ligament of the liver and anastomosed with the hepatic artery in the substance of the liver; small branches of the inferior thyroid artery anastomosed on the longus colli muscle with branches of the intercostal arteries; a descending branch of the profunda cervicis artery running down on the semispinalis muscle joined the posterior scapular arteries; the inferior thyroid artery on each side was a branch of the common carotid. The deformity in this case was, as it probably is in all of these cases, due to a faulty development of the part of the fourth left branchial arch, which extends from the left subclavian artery to beyond the ductus arteriosus. The heart, which was also exhibited, showed extreme hypertrophy of both sides, all the cavities were much dilated, the dilatation keeping pace with the hypertrophy. In the apex of the ventricular wall was a large patch of fibroid degeneration. It was pointed out how extremely rare the deformity was, very few cases having been recorded, and only one of these had been diagnosed during life. The age to which patients thus deformed attained varied very much, for one man lived to be ninety.

DR. HOBSON read for himself and DR. LANCHESTER the notes of a case of Caseous Pneumonia of the Entire Lung simulating Empyema, with general Tuberculosis, which occurred in a little girl who died seventeen weeks after an acute attack of disease following on a term of delicate health. The symptoms and physical signs were those of an empyema of the left side, including marked bulging and displacement of the heart to the right. Upon this diagnosis the chest was tapped in several places, and also incised, but with negative results. A drainage-tube was, however, inserted into the wound, which continued to discharge sero-pus to the end. A spontaneous opening formed subsequently at the seat of one of the punctures in the axilla, and purulent fluid continuously drained through this. The surgical treatment was strictly antiseptic. A few days before death symptoms of tubercular meningitis came on. After death there was found to be no pleuritic effusion, but the whole of the left lung was solid, distended, and filled with dry caseous material, which, however, had softened down and left a cavity in the superficial parts of the upper lobe corresponding to the axillary opening. The artificial opening simply led into a blind channel in the lower lobe. The right lung was studded with miliary tubercles. There were also tubercles in the fatty liver, in the kidneys, and spleen. There were tubercular ulcers in the small intestines. The microscopical appearances in the affected lung showed thickening of pleura, a decided but not uniform thickening of the alveolar walls, and the alveoli stuffed with inflammatory products in which epithelial elements could only occasionally be traced. As far as the experience of the authors went this case was unique. The sign which of all others is regarded by writers as diagnostic of effusion as from pneumonia—viz., displacement of the heart and bulging of the chest walls—was here present. The uniform consolidation and caseation of the entire lung, with an absence of a similar process on the opposite side, was also remarkable. The only cases which seemed at all parallel were those that have been described by Virchow, Wagner, and others as syphilitic pneumonia in infants. The possibility of syphilis in this case seemed to be out of the question.—DR. GOODHART had seen one other case which was exactly like it. It was, he thought, not a rare condition. He considered that the disease was one of childhood. It was not a syphilitic form of pneumonia in his opinion. In many respects it resembled a tumour of lymphomatous structure.—DR. DYCE DUCKWORTH did not think that a caseous bronchial gland could originate such extensive disease as had been exhibited in this specimen.—MR. H. T. BUTLIN recalled two cases in his experience at the Hospital for Sick Children.—DR. ANGEL MONEY had met with two cases of

Digitized by Google

diffuse pneumonia which simulated empyema during life out of 300 autopsies.—Dr. SAMUEL WEST spoke of the frequent mistake which had been made in diagnosing between consolidation and pleuritic effusion. The specimen shown by Dr. Hebson reminded him of a sarcomatous growth.—Dr. LANCHESTER said the microscopical as well as the macroscopical characters were different from those of syphilis. No other conditions than pleuritic effusion and this form of consolidation could give rise to bulging of the chest walls, displacement of organs, and the other physical signs.

Mr. ARTHUR E. BARKER read notes of a specimen of Tubular Epithelioma. The sections and drawings exhibited were taken from an epitheliomatous tumour of the left upper jaw, on account of which Mr. Barker had removed that bone more than four years ago, the patient having been exhibited last May to the Society without any trace of recurrence. The whole of the bone was removed with the exception of a part of the orbital plate, the corresponding part of the soft palate being left intact. The tumour was extensive, but distinctly limited, and did not involve any glands. The recovery was rapid and complete. Sections of the growth showed an almost adenoid structure. The groundwork consists of a well-developed, smooth, fibroid tissue, in which large groups of cells are arranged in a manner recalling, in part of the growth, the whole of a racemose gland, in other parts resembling tubular glands in section. In the centre of most of these groups is a lumen, in some apparently the result of mucous degeneration, in others appearing like the central lumen of a gland lobule. The cells composing the lobule are arranged without any regularity towards its centre in some cases, but are more evenly placed peripherally as a rule. They are smaller than ordinary glandular epithelium, but suggest the latter on the whole rather than that they are connective tissue derivatives. The growth appears to be identical with those described by Mr. Eve as "multilocular epitheliomata," also found in the upper jaw. The slowness of its growth (three years), the distinct limitation of its border, and the immunity from recurrence, offer a marked contrast to most other epitheliomata, but are what we would expect from an examination of the structure of the growth, which shows a high differentiation of structure, and consequently a diminished malignancy in every way.—Mr. H. T. BUTLIN said that the specimen was not an epithelioma; it appeared to be a carcinoma, or a tumour which had hardly passed into carcinoma. It was not like the cases which M. Terrier described under the designation of "boring" epithelioma of the upper jaw, which was of a very malignant nature and greatly destroyed the osseous structures.—Mr. HARRISON CRIPPS would not have described the specimen either as an epithelioma or carcinoma, but as more allied to true adenoid growths. He believed that the growth was of a papillomatous or "cauliflower" structure, what appeared to be spaces being really the stalk, which was coated by the regular layers of epithelium.—Mr. W. HULKE asked whether the structure were equally distinct at the extreme periphery of the tumour as in the centre.—Mr. BARKER replied in the affirmative. He suggested that the specimens be referred to the Morbid Growths Committee.

Dr. PERCY KIDD read a paper on four cases of Cardiac Aneurysm. In the first case, which was that of a man, aged twenty-three, the aneurysm of the undefended space was obviously of congenital origin, and due to imperfect development of the membranous part of the ventricular septum. The dilatation of one sinus of Valsalva was no doubt the result of atheroma. The second and third cases, which occurred in men, aged twenty-one and forty-three respectively, illustrated the influence of friction of pendulous vegetations against the cardiac walls, the resulting erosion of the endocardium being the starting-point of an aneurysmal bulging. In both these cases there had been rheumatic fever, and great pain in the præcordial region was a prominent symptom during life. In the fourth case, that of a man aged forty-seven, the aortic valves and aneurysm were the seat of a marked fibroid change, and there were no traces of endocarditis. The patient had frequently had chronic rheumatism, but it is doubtful whether he ever had rheumatic fever. It is now well known that aneurysm of the heart is dependent on a gradual yielding of some diseased part of its walls to the intracardiac blood pressure. Of the four cases under consideration, all but one were instances of aneurysm resulting from endocarditis, acute or chronic, of rheumatic origin. In all four cases the aneurysm occurred in males.—Dr. ANGEL MONEY referred to the case of a female child, aged five years, who was idiotic. At the autopsy an aneurysm was found at the site of the undefended space. The aneurysm opened up the laminæ of one of the flaps of the tricuspid valve; all the valves were in a "pouchy" and thickened state. In the right cerebral hemisphere there was a tumour, probably gummatous, the size of a Tangerine orange.

Dr. HOWARD TOOTH read notes of a case of Diffused Lympho-sarcoma of the Liver. The specimen was taken from a child aged five, who had been in perfect health till within six months of her death, during which time she had lost flesh rapidly, and suffered from diarrhœa and epistaxis. At the post-mortem examination the glands of the neck were slightly enlarged; there were tubercles in both lungs, some caseating; the bronchial glands were not enlarged. The spleen and kidneys were natural, but pale. The abdominal lymphatics were apparently normal. The liver was uniformly enlarged, its surface smooth, its colour nearly white, and weighed forty-eight ounces. No isolated growths were seen. Microscopically the liver was found to be infiltrated with small round cells. Near the surface of the organ there was not so much glandular destruction as towards the centre. A considerable amount of fibrous tissue was seen in the central part of the organ. This condition was a very uncommon one, especially in so young a child. It might be taken for a leukæmic enlargement, but there was no concomitant enlargement of the spleen or lymphatic glands, neither was it likely to be cirrhotic in nature. The amount of connective tissue was small, and there was no history of jaundice or ascites.

Dr. THEODORE ACLAND brought forward two cases of Paraplegia, in which there had been great ulceration of the intestines. The clinical history of the two cases was very similar; both had contracted syphilis, and in both of them the disease, which resembled simple softening of the cord, ran a comparatively rapid course; the one terminating in less than three weeks, the other in less than a month, from the onset of the disease. In both cases the ulceration had been mainly confined to those parts of the bowel which had been most distended, in the one case occurring in the small intestine, in the other in the stomach and colon. The question naturally arose whether the lesion of the central nervous system stood in any causal relation to the ulceration of the bowel. The more usual causes of ulceration of the bowel were severally discussed: tubercular, syphilitic, cancerous, and typhoid ulceration being successively excluded. With regard to the last form of ulceration it should be noted that in one case Peyer's patches were chiefly affected; the lesion, however, was like a simple loss of substance rather than an inflammatory affection of the glands, and the temperature was quite unlike that of a well-marked case of enteric fever, since, after the first rise to 102°, the temperature never rose above 100°, and was more often subnormal. The question was then raised whether the lesions might not be a simple ulceration due to distension, or whether they might be due to loss of nerve power and formed on the principle of a bedsore, by great internal pressure occurring in a viscus whose distension was due primarily to the lesion of the nervous system. In support of this view, it was urged that in the case of which the affected parts had been submitted to a microscopic examination the chief injury seemed to be in the dorsal region of the cord, which implied a probable implication of the roots of the thoracic ganglia, which gave rise to the splanchnic nerves. A series of microscopic and macroscopic specimens was exhibited in support of the view taken by the speaker.

Mr. VICTOR HORSLEY showed a recent specimen of Artificial Myxœdema in a Monkey. It exhibited the macroscopic appearances fifty-four days after removal of the thyroid body. There were opacity and a gelatinous sticky state of the connective tissues throughout the body; great swelling of the salivary glands, which were pale and semi-translucent; atrophy of the muscular substance of the lower border of the right ventricle of the heart; swelling of the spleen, and commencing atrophy of the cerebral convolutions.

The following card specimens were exhibited:—Dr. Charlewood Turner: Hæmatoma of Dura Mater, and two cases of Endocarditis with Ulceration.

MEDICAL SOCIETY OF LONDON.

A GENERAL meeting of this Society was held on Monday last, Mr. Arthur E. Durham, F.R.C.S., President, in the chair.

Mr. EDMUND OWEN read a paper on Lancing the Gums. Not many years ago every practitioner carried about a lancet case, now the thermometer had to a great extent supplanted

Digitized by Google

it. Indeed, that excellent thin-bladed instrument had fallen into unmerited neglect. Probably improved methods of diagnosis had shown that many of those ills which were previously ascribed to dentition, because they happened to accompany it, had really no dependence upon it. Dentition used to be regarded too much as a mechanical process; a tooth was on the wrong side of a tough gum and had to be helped through by scarification. Mr. Owen maintained that dentition was a simple physiological process, and that it stood in little need of professional assistance. The belief seemed somewhat widely spread amongst the laity that dentition was rather a clumsy, if not a cruel, matter. "My children always cut their teeth with a big head," says one mother. Should it not rather read, "My children are improperly fed, and are rickety"? There was a special trouble apt to be associated with teething, and that was infantile paralysis. The practitioner should be always on the watch for it; its very symptoms were apt to obscure it, and when the limbs became wasted or deformed bitterness was apt to be expressed by the mother because the doctor had assured her that that feverish attack of many months ago was "only from teething." What, he would ask, was the exact condition of gum which required scarification? Was the gum often found swollen and tender from an attack of congestion or inflammation, the direct result of dentition? If such cases are of frequent occurrence, who sees them and officiates? For his own part, he had carried a lancet in his card-case for years, but he had never yet found work for it upon a child's gum. Possibly others might give a different experience, and describe lancing the gums as a "good remedy out of fashion." Would the dental surgeons give their experience of the actual or probable effect of scarification upon the development of the teeth? In England the operation was at one time very much the fashion; now one hears little of it.—Dr. C. GODSON was sure that teething did cause pain, and that the lancet was useful.—Dr. BRAXTON HICKS agreed with the previous speaker. It was necessary to bear in mind the delicate nervous organisation of the infant. He thought that the eruption of the teeth was attended with reflex phenomena of disturbance. — Dr. PARAMORE also concurred with the views of the previous speakers.—Mr. HAMILTON CARTWRIGHT spoke chiefly of the dominance of the nervous system of the infant as an argument in favour of lancing the gums. He felt sure that diarrhœa and convulsions were caused by tension of the gums. Lancing the tumid glistening dental sac was of the greatest importance.—Dr. C. J. HARE said that his optimism had received rude shocks in the course of his existence. Fashion dominated everything. So it was with bleeding, which even now was capable of saving many lives. Abstraction of blood from the gums was a valuable remedy.—Dr. WEBB testified to the efficacy of lancing the gums.—Dr. SANSOM did not consider that the eruption of the teeth was a physiological process in the sense that it was not liable to great disturbances. He thought that there was a liability to go too far in the direction of lancing the gums. He referred to the association of diarrhœa with dentition, and found statistically that the greatest accession of diarrhœa coincided with the period of eruption of the first temporary molars. — Dr. S. TAYLOR thought the lancet might be abused as well as used. Injudicious rubbing and chewing was responsible for the hard and horny cuticle which sometimes coats the gums.—Mr. LOWNE said that nine out of ten cases of infantile diarrhœa were due to improper feeding. He could not understand how the eruption of the teeth could reflexly cause diarrhœa. He did not know that he had ever done any good with the gum lancet.—Dr. RADCLIFFE CROCKER thought that the instances in which the gum lancet could be used with advantage were few. Dentition was made to serve as the cause of almost every disease to which children are liable.—Dr. W. DUNCAN had seen a goodly number of cases of diarrhœa and convulsions which he was positive were due to dentition. He did not think that the mere abstraction of blood was of any value in relieving the sufferers.—Dr. TRAVERS had not seen a single instance in which he felt justified in using the lancet in the last nineteen years.—Dr. EWART said he was a firm believer in the value of lancing the gums, though in his experience it was but rarely required.—Dr. DREW believed that lancing of the gums would be necessitated in febrile conditions associated with pains in the gums lasting more than two days. Diarrhœa, bronchitis, and suppuration of the middle ear might be caused by dentition.—Dr. DE HAVILLAND HALL said that since the introduction of bromide of potassium into therapeutics the lancet had probably fallen into disuse. — Dr. PARAMORE asked whether any harm had been done by lancing the gums.—Mr. PEARCE GOULD believed that the bleeding resulting from lancing the gums had sometimes proved fatal.—Mr. EDMUND OWEN, in reply, felt sure that lancing of the gums had been practised too much.

HARVEIAN SOCIETY OF LONDON.

A MEETING of the above Society was held on Thursday, October 16th, Mr. George P. Field, President, in the chair.

Interstitial Keratitis.—Mr. JULER, in a paper on this subject, referred briefly to the well-known changes noticed in the tissue of the cornea as a result of chronic inflammation, and dwelt upon the leading clinical features and upon the treatment of the affection. One eye was usually affected for two or three months before the disease extended to the other eye. Pain and photophobia were symptoms subject to much variation; photophobia, when present, generally pointed to the existence of superficial ulcerations. Prognosis was favourable, the opacity ultimately clearing up completely, but the process of cure was slow. The systematic administration of grey powder and of tonics, and the local use of atropine, were eminently successful. A congenital syphilitic taint could be traced in at least 90 per cent. of the cases, and with this marked anæmia was generally combined.—The PRESIDENT alluded to the frequency of interstitial keratitis in cases of diseases of the ear. In his experience girls were affected in a much higher degree than boys.—Dr. JAMES THOMPSON expressed his firm belief in the syphilitic nature of the affection, and in its curability by mercury. Dr. Thompson called attention to a sign of congenital syphilis, never absent in these cases, and to which he had found no reference in medical literature. In syphilised children, instead of the clean frontal line formed by the healthy hair of the scalp, an irregular border of fine fluffy hair, about half an inch to one inch wide, is almost invariably present.—Mr. HARTRIDGE referred to the persistence in the cornea, after apparently complete cure of the opacity, of fine lines or stripes, due to the obliterated vessels of the "salmon-patch" of Hutchinson. A case was mentioned in which the keratitis was the outcome of acquired syphilis.—Dr. BUZZARD wished to remind the Society that the great advances made in the pathology and in the treatment of the affection were mainly due to Mr. Hutchinson's teaching. The syphilitic nature of the disease was no longer a matter of doubt, and the propriety of a mild mercurial treatment could hardly be questioned.—Dr. ALDERSON gave the full particulars of a case which exemplified the insidious mode of onset sometimes observed; the patient recovered perfect vision under the administration of grey powder and quinine, with occasional purgatives.

A Demonstration on the Mechanical Principles of Surgical Apparatus, by Mr. NOBLE SMITH.—He remarked that although the application of splints and their management in the treatment of ordinary fractures received a full share of attention in lectures and in text-books, the use of apparatus for orthopædic cases was seldom adequately dealt with, and the principles which ought to guide the surgeon in devising and in using such apparatus were almost entirely ignored. The student, left in ignorance of these matters, was obliged in after years to rely too much upon instrument makers, whose knowledge of surgery was necessarily incomplete. Mr. Noble Smith demonstrated by means of a lay figure the principles which he thought should be followed in applying a splint for hip-joint disease; he also explained by means of diagrams his views as to the successful use of apparatus in cases of diseased spine, of knock-knee, of bowed legs, and of other orthopædic affections.—Referring to some of the author's remarks, Dr. JAMES THOMPSON stated that he had recently removed a plaster jacket which had been worn for three years without any interruption. The skin presented no abrasions or marks of any kind, and the boy had felt comfortable throughout. There remained no trace of any spinal deformities.—Mr. R. FITZROY BENHAM did not regard the model exhibited to be an accurate illustration of diseased hip-joint. The pain stated to be produced by mere extension of the limb was not brought about by pressure of the fluid against the upper part of the acetabulum, but by contact of the opposed inflamed surfaces. He failed to see the difference between the

Digitized by Google

apparatus exhibited and the apparatus known as Thomas's splint. Mr. Banham did not consider a padded back-board to be the best means of support in Pott's disease, but preferred the poroplastic jacket. Sayre's plaster jacket, unless applied with great care, might be worse than useless. He did not agree with Mr. Noble Smith that in severe cases of genu valgum it was advisable to allow the patient to go about with walking instruments until the inner malleoli could be brought together by means of appropriate supports, rest, and, above all, manipulation.

CAMBRIDGE MEDICAL SOCIETY.

AT a meeting of this Society, held on October 3rd, Professor HUMPHRY read the notes of a case of Spontaneous Fracture of both Thigh Bones. S. L——, aged fifty-six, a healthy-looking woman, broke her right thigh bone under the following peculiar circumstances in 1855. For several years previously the limb had been subject to pain, chiefly about the middle of the thigh. A month before it broke the pain was worse and she could scarcely lift her foot from the ground. Two days before it broke she caught her toe against the stair; this caused sharp pain in the thigh and a lump formed near the middle. She was walking, when it seemed as if the left foot caught, and she fell; but she is sure that she felt the right thigh break before she reached the ground. It was treated by a surgeon with splints, and united in about five weeks; the pain disappeared and the limb got quite strong. She remained quite well till soon after Christmas of 1856, when a pain came across the left thigh, similar to that which she had before experienced in the right. The limb was in very much the same condition as the other before it broke, and the pain was very bad, so that she feared it would break. On March 1st, it broke in much the same way as the other; she made a kind of stumble and felt it break before she reached the ground. She was admitted into Addenbrooke's Hospital and a long splint applied. The parts united in the usual time and became quite firm. The pain left the thigh, but she began to complain of pain in both arms a little below the shoulder. The patient was soon after unfortunately lost sight of. Professor Humphry referred to three cases recorded by Mr. Henry Smith of spontaneous fracture of the arm, in which rheumatic pains had been felt previous to the fracture. Also to one by Mr. Holmes of fracture of the femur in a stout young man whilst walking across the room, union taking place readily. The cases to which he wished to draw particular attention were those in which a bone suddenly gives way in a tolerably healthy person, the fracture often preceded by pain, and union taking place as early and as well as in other fractures. All these features were well illustrated in the remarkable case he had first related. Whether there was some inflammatory condition of the bone or some disorder of the trophic nerves previous to the fracture he was unable to say, but they were distinguished from other cases in which spontaneous fracture occurred, for instance, in mollities ossium, in cancer, locomotor ataxy, or from violent muscular action.

Mr. CRIBB (Bishop Stortford) communicated a case by letter, of a boy, aged eight, who in turning himself in his carriage Fractured his Left Femur.

Mr. ALEX. HILL exhibited a specimen of Epignathus which he had received through the kindness of Dr. Sunderland, of Thaxted, Essex, and had dissected with a view to discover if possible the explanation of this form of monstrosity. The autosite was a well-formed seven months' female fœtus. The parasite which depends from its mouth and nostrils without in any way causing their malformation, and very slightly distending the mouth, consists of a number of larger and smaller cotyledons with a total size rather greater than that of the head of the autosite. A cotyledon about the size of a chestnut with a narrow stalk projects from each nostril. One of those projecting from the mouth presented a considerable superficial resemblance to an ill-formed fœtal head with mouth and hairy scalp and central core of bone. After careful dissection Mr. Hill came to the conclusion that this resemblance was only accidental. Another mass, of the size of a bantam's egg, was covered only by a transparent membrane, and consisted of irregular columns of liver cells scattered through a matrix of fœtal connective tissue. This rudimentary liver was profusely supplied with bloodvessels. The stalk of the parasite was attached only to the basi-sphenoid and back of the vomer. It received a large artery from one of the pharyngeal arteries on the left side, and also a small artery from the left internal carotid inside the skull, communicating with a minute branch from the right internal carotid, and descending through the open pituitary canal. The brain, including the hypophysis cerebri, was perfectly normal. No specimen of this form of monstrosity is to be found, as far as Mr. Hill is able to discover, in any of the museums in Great Britain or Ireland.

Dr. CROWDEN (Waterbeach) reported a case of Concretions in the Pancreas (specimen shown) extending over twenty-five years. W. B. C——, married, aged fifty, robust and of temperate habits, consulted him in 1880, giving the following history. About his twenty-fifth year he suffered from scrofulous glands in the neck, for which he underwent a long course of iodide of potassium. Two years after he suffered occasionally in the morning from great pain in the epigastrium. The attacks soon became paroxysmal, and were considered to arise from indigestion; they increased in frequency and severity, chiefly during the effort of defecation, and were accompanied with peculiar emotional phenomena. When seen during the paroxysm his countenance was pallid and bathed with perspiration, expressing the greatest agony. Before his death, which occurred suddenly, he became very restless and exhausted. At no time were there any physical signs, and the symptoms were so masked by the emotions of the patient that during life the case was never recognised. The post-mortem examination revealed a hard substance near the centre of the pancreas, the head appeared natural, but, extending from about the middle of the body, a line of prominences could be seen running along the long axis to the tail, accompanied by great structural change. Some of these masses were very pointed, denuded, and projected under the areolar tissue and peritoneal covering. The lower part consisted of one amorphous mass of concretions without any soft gland structure. The peritoneum and wall of the stomach close to the sharp points were acutely inflamed, but there was no effusion. The concretions consisted of carbonate and phosphate of lime.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

A MEETING of the above Society was held on Oct. 9th, Mr. W. A. Garrard, President, in the chair.

Mr. GARRARD read a paper on the Treatment of Wounds. He thought we owed a debt of gratitude to Sir Joseph Lister whether we adopted his treatment of wounds or not, for he had been the means of bringing home to every surgeon the importance of personal attention to every detail of dressing as well as absolute cleanliness, thus making it possible for the humblest provincial surgeon to obtain results equal to those of the most eminent, except in such cases as opening large joints and deep cavities, as empyema, psoas and other deep abscesses connected with carious bone. He did not adopt his method in all its details, believing that as good results were obtained by simpler means. In amputations and other large wounds, he washed them first with hot iodine water, as recommended by Mr. Bryant, and then dressed with dry absorbent cotton, drainage, when necessary, and gentle elastic pressure, keeping the wound always dry. He considered the absorbent cotton impregnated with salicylic acid was much better than the favourite gauze, which was not sufficiently absorbent to keep the wound dry. Taking the last seventy-nine cases at the Rotherham Hospital, and excluding four who died in a few hours from very severe injuries requiring double amputation, there were four deaths. One was an old man, who had both legs amputated for severe injury, and died on the fifteenth day; another on the sixth day, after herniotomy, the hernia having been strangulated eight days before admission; the bowel sloughed. Neither of the two other cases died from blood-poisoning. For the arrest of hæmorrhage Mr. Garrard, whilst admitting that the catgut ligature was an excellent method, much preferred torsion, which he always adopted, believing it to be the simplest, the nearest approach to nature's own method, and not liable to be followed by secondary hæmorrhage. He had never seen an artery bleed again after having been once properly twisted, and had never had to reopen a wound on that account.—Dr. BANHAM, Mr. PYE-SMITH, Mr. ATKIN, Dr. PORTER, and Mr. WALKER joined in the discussion which followed.

At the meeting on October 23rd, the President in the chair, Mr. SNELL exhibited a section of Bony Tumour of Conjunctiva, as described in the Transactions of the Ophthal-

Digitized by Google

mological Society; and also small flat Mirrors for Retinoscopy, as suggested by Mr. Priestley Smith, the cost being only a few pence each.

Dr. BANHAM introduced a patient suffering from Unrhythmical Spasmodic Torticollis, and who had been affected in this way for about ten months. The patient had been under his care at the infirmary four months previously, and after a few weeks' treatment with full doses of bromide of potassium and the application of galvanism to the affected muscles she had greatly improved, and left the infirmary of her own accord. Three weeks ago she again presented herself; the spasms were then more violent than ever. Previously when in the infirmary the spasms were limited apparently to the right trapezius and right sterno-cleido-mastoid, and could be arrested by firmly grasping the trapezius near its attachment to the occiput, or by the patient lying on the left side, with the left side of the face fixed firmly against the pillow. The spasms were not now so influenced, or to a much less degree, and the left trapezius seemed also involved, so that the head was now often thrown back, the neck being arched to its utmost possible limit. There was no history of syphilis, and no catamenial irregularity, excepting to a slight degree during the last four months. Dr. Banham remarked that the etiology of these cases was very obscure. He could find no cause for the symptoms appearing in the patient. She was an intelligent woman, the mother of several healthy children, and never exhibited any trace whatever of hysteria. He had seen a large number of somewhat similar cases, and he felt that they ought not to be dismissed as of no moment; they sometimes did badly, ending in epilepsy, idiocy, or death. When the movements were rhythmical he thought the prognosis more favourable.

Mr. C. ATKIN read the notes of a case occurring at the infirmary in the practice of Mr. Favell, in which he had ligatured the Brachial Artery for Secondary Hæmorrhage after amputation on the upper third of the forearm, with an immediate marked effect on the inflammatory condition of the stump. Though the flaps healed externally by the first intention, the whole limb went into a state of over-reaction after the amputation, and a general arterial oozing occurred on the tenth day. After ligation of the brachial artery the hæmorrhage ceased, and the limb, which before had been swollen to twice its natural size, dark-red, doughy, and semi-fluctuating, resumed its normal form and colour in a few hours.—Mr. JACKSON remarked that deligation for the arrest of hæmorrhage was first performed in England by Mr. Favell at the suggestion of Mr. G. A. Brown, then the house-surgeon of the Sheffield Infirmary, and now of Tredegar. Mr. Brown had already had a case in which sloughing phagedæna of the palm had been arrested by the ligature of the radial and ulnar arteries for hæmorrhage.—Mr. KNIGHT and Mr. BROWNING also made observations.

Dr. C. H. WILLEY read a paper on the Recent Epidemic of Small-pox in Sheffield. The epidemic commenced in February, and ended at the end of September last. During this time 203 cases were admitted into the Borough Fever Hospital. Details of these 203 cases, as regards the influence of vaccination on the type of the disease, complications, length of illness, and mortality were given—150 had been vaccinated, 4 revaccinated, and 49 unvaccinated. The mortality among the vaccinated and the unvaccinated respectively was 4½ and 28½ per cent. Of the vaccinated, 77 per cent. were of the two milder types, and of the unvaccinated 96 per cent. were of the two most severe types. The average duration of the illness was for the vaccinated twenty-two days, and for the unvaccinated forty-two days. Of the four revaccinated cases, three were not vaccinated until after they had contracted the disease, in the fourth case an interval of thirty-six years had elapsed since the operation. Complications occurred in 12 per cent. of the vaccinated and 71½ per cent. of the unvaccinated.—The following gentlemen joined in the ensuing discussion; the PRESIDENT, Mr. SNELL, Mr. LONGBOTTOM, Mr. WALKER, Mr. BROWNING, Mr. SUMNER, Dr. DYSON, Mr. A. JACKSON, Mr. KNIGHT, Dr. LEYTH, Mr. RECKLESS, and Dr. MARTIN.

THE Local Government Board have finally "ordered" the guardians of St. Saviour's "to cause a new infirmary to be erected (at Champion-hill) at a cost not exceeding £93,163"; the fittings and furniture are not to exceed £20,000.

Reviews and Notices of Books.

Intestinal Obstruction, with an Appendix on the Action of Remedies. By HUGH OWEN THOMAS, M.R.C.S. *Abdominal Hernia.* By RUSHTON PARKER, B.S., F.R.C.S., Professor of Surgery in University College, Liverpool. London: H. K. Lewis. 1883.

THE second part of this volume, consisting of Mr. Rushton Parker's essay on Abdominal Hernia, has already been noticed by us, when it appeared in a separate form. By far the greater part of the book before us is from the pen of Mr. H. O. Thomas, who is chiefly known to the profession as the inventor of excellent splints for the treatment of diseased joints. Mr. Thomas has certainly fulfilled one of the conditions of successful authorship; he has had something to say, and that "something" is to a large extent valuable to the profession. Unfortunately the manner in which the book is written is such as sorely to try the reader's patience, and to quickly put him out of sympathy with the author. Sentences are met with which are so involved as to be almost incomprehensible, and the most round-about phraseology is used to express imperfectly and inexactly quite simple facts or views. The criticism of the teachings, writings, and practice of many of the most distinguished contemporary physicians and surgeons as well as of other times is in a style that is happily not common, and which for bad taste is only equalled by the care taken to show that the problem which has hitherto puzzled all physicians and surgeons has at length been completely solved by Mr. Thomas, and that the treatment of intestinal obstruction is at length and for ever established on a true and scientific basis. These are errors which appear on the surface, and must arrest attention, and we can well believe that many would be inclined to put aside the book as useless on the assumption that no sound grain would be mixed with so much chaff. But it is not so. Mr. Thomas's teaching is well worthy of the careful attention of the profession, who will not be at a loss to see the extent of its value. The first point insisted on by him is the absolute necessity of withholding purgatives in every stage of the treatment of all cases of "intestinal obstruction," even the mildest. He insists over and over again that quite mild and easily curable cases of "obstruction" are quickly converted into severe and even fatal cases by the administration of purgatives. He also discountenances the use of enemata, purgatives (simple or nutrient), the introduction of long rectal tubes, inflation of the colon, or even digital rectal exploration. He teaches that all these are practically useless, and actually harmful from the peristaltic action they excite in the intestine. This may be called the negative side of the treatment recommended. The positive is this: morphia is to be given subcutaneously in amount sufficient to allay pain, and to lessen or to control entirely the vomiting, but vomiting once or twice a day is looked upon as a proper relief of the distended intestines so long as the obstruction lasts, and not as a symptom to be removed entirely. The diet is to be entirely liquid—not milk—and given in small quantity. This treatment is to be continued for some time after the "obstruction" is overcome. As adjuncts, the foot of the patient's bed is to be raised, cold wet cloths may be placed on the abdomen, and if the distension become extreme and percussion yield a uniformly clear note, paracentesis is to be performed with a fine trocar and cannula, and repeated as often as may be required. Mr. Thomas is generally opposed to operative interference, but when the treatment he recommends has been carried out with strict exactness, and the pulse continues or becomes rapid, "while the tongue has the typhoid appearance with intense thirst, and the vomiting exceeds four times in twenty-four hours, this condition, with or without collapse, indicates the necessity for considering

Digitized by Google

the advisability of resorting to surgery. ..... These are the signs indicative of the time when the patient ought to be given the chance that can be afforded by a surgical operation." It is only necessary to add that Mr. Thomas treats all cases of failure to pass the intestinal contents with due regularity and frequency in the same way, with the single exception of external hernia, although it is not made apparent why the treatment of strangled bowel in the scrotum or groin is not amenable to the treatment which we are given to believe is the only course proper to follow in the precisely analogous condition within the abdominal cavity. We therefore read nothing of differential diagnosis of the various forms of internal intestinal obstruction, except certain brief, almost contemptuous references to it as unnecessary for guidance in treatment. Notes of several cases are included in this essay; the great bulk of them are cases of typhlitis and of enteritis, and among them are two or three cases of enteric fever. The treatment is good so far as it goes, but in that it to a large extent ignores the various causes of intestinal obstruction it stops far short of what is desirable. All who read this essay will be repaid, and will thank Mr. Thomas for his strenuous insistance on the evil effects of purgatives, and for his judicious directions for the feeding of these patients. We are conscious that there is real merit in this book, and regret that it should be marred by the defects to which we have referred.

OUR LIBRARY TABLE.

Hygiene: a Manual of Personal and Public Health. By ARTHUR NEWSHOLME, M.D. Pp. 408. London: Gill and Sons. 1884.—The author informs his readers in the preface that this work was written from the notes of the lectures he delivered at Exeter Hall, to the students preparing for the examination in hygiene of the science department in the advanced stage. We congratulate the students on having had the subject brought before them in so clear a manner. The book appears to us remarkably well adapted for a handbook for the study of the principles of public and personal hygiene. It brings under consideration the various subjects treated of in clear and intelligible language, and points out the measures necessary for the prevention of disease and the promotion of health and comfort. We strongly recommend the book to the attention of the public generally, as containing much valuable information and advice. In addition to a full table of contents it has the advantage of a copious index.

Studies in Life. By H. SINCLAIR PATERSON, M.D. Pp. 187. London: Hodder and Stoughton. 1884.—This, like the Health Studies by the same author, which we recently noticed, appears to consist of a course of eight lectures, delivered to a society of young men. It treats of life and its characteristics, its origin, varieties, record, natural history, enemies, and results. In it the views of Huxley, Darwin, Tyndall, and Herbert Spencer are discussed in a temperate and fair spirit; the enemies of life are brought under consideration, especially pestilence, famine, intemperance, and the insanitary conditions which give rise to disease; and the lessons taught under the "results of life" are well deserving of serious consideration. The book is calculated to promote the purpose for which it was written, and to satisfy the young men to whom the lectures were addressed that "life is full of meaning, full of power, and full of grandeur, when we look at it in the light of God's Word, and when we accept the teaching that Word gives us concerning its present purposes and its eternal issues."

The Medicine Stamp Tax. By C. E. MEETKERKE. London: Wyman and Sons. 1884.—The question of the repeal of the Medicine Stamp Tax has of late attracted so much attention that we record with pleasure the appearance of a work which deals exhaustively with the subject. It is, we believe, mainly due to the action of THE LANCET that the matter has been so warmly taken up by almost all classes of society. Nearly two years ago we pointed out the evil of a practically unlimited sale of poisons under the thin but misleading guise of "patent medicines." It would not be tolerated for a single instant, but that a considerable income is derived from the sale of stamps. We are glad to find that the author of the work before us entirely coincides with this opinion, and considers that it is a disgrace to the State to derive income from a source which is clearly not for the public good. The arguments are set forth clearly and logically, and in a manner calculated to carry conviction to the mind of the reader. The Chancellor of the Exchequer will do well to study it carefully.

Canadian Pictures, drawn with Pen and Pencil. By the Marquis of LORNE, K.T. With numerous Illustrations from Objects and Photographs in the possession of, and Sketches by, the Marquis of Lorne, Sydney Hall, &c. Engraved by Edward Wymper. London: Religious Tract Society.—To all who are interested in the history and present condition of Canada—and they are a numerous and increasing class—this handsome volume will be very welcome. It teems with information acceptable alike to the political economist, the naturalist, and the intending emigrant; whilst the beautiful illustrations, the graphic descriptions, and the judicious comments with which the book abounds must gain for it a favourable reception with the general reading community. In order to lessen the amount of ignorance prevailing amongst the British public of the affairs of England's dependencies, the noble author of the volume suggests that information respecting them might with advantage be systematically imparted in the course of instruction adopted in our universities and schools. On the question of climate the author corrects some prevalent misapprehensions. The climate of Canada, he says, has honest heat in summer, and honest cold in winter. Sometimes the thermometer indicates 90°F. in August and 30° below zero in January. But the dryness of the air is so great that the inconvenience and disaster which such intense cold might be expected to entail on the inhabitants are but little felt. McGill University comes in for a brief notice. It is described as a popular seat of learning, with an ever-increasing roll of students in all the faculties, and a gradually lengthening list of endowments. The author gives some interesting sketches of Indian life and customs. The natives are credited with a considerable amount of skill in the use of herbs as remedies for slight ailments; the squaws especially are adepts in the making of decoctions and poultices from trees and shrubs whose healing properties are known to science, and instances of remarkable relief having been obtained by the exhibition of Indian medicaments are narrated. The natives make great use of the sweating bath, which consists of a small arbour formed of interwoven branches of trees, within which are placed heated stones, the steam being generated by pouring water over them. No one can read this book without being impressed with the importance of the "New Dominion" to the interests of the mother country. Its features are portrayed in glowing colours by one who is well qualified to judge of its merits, and who concludes his book by exhorting "those who see the misery, the hopelessness, the overcrowding, and the unhealthiness of the thronged quarters of our great cities" to "rejoice that within fourteen days of London, Glasgow, Liverpool, and Manchester land and healthy life can be provided for all sound in health and limb."

Journal of Anatomy and Physiology. Vol. XIX. Part 1. October, 1884. Edited by PROFESSORS HUMPHRY, TURNER, and MCKENDRICK. Macmillan and Co.—This part contains the following memoirs:—1. Histology of the Vitreous Humour, by Arthur C. Young, and Plates 1 and 2.

2. The Comparative Variability of Bones and Muscles, with Remarks on Unity of Type in Variations of the Origin and Insertion of Certain Muscles in Species unconnected by Unity of Descent, by G. E. Dobson, F.R.S. 3. Congenital Malformation of the Trachea of a Horse, by F. Smith. 4. Nature of Ligaments, by J. B. Sutton, and Plate 3. 5. Osteology of Numenius Longirostris, with Notes upon the Skeleton of other American Limicolæ, by R. W. Schofeldt, and Plates 4 and 5. 6. The Anatomy of Acquired Flat-foot, by J. Symington, and Plate 6. 7. New Method of cutting Sections for Microscopical Examination, by James W. Barrett, M.B. 8. New Method of demonstrating Scheiner's Experiment, by James Barrett. 9. Abnormal Disposition of the Colon, by R. Bruce Young. 10. Delineation of Skulls by Composite Photography, by Arthur Thomson, and Plate 7. 11. Repair of Wounds and Fractures in Aged Persons, by Professor Humphry. 12. Case of Abnormal Development of the Coronary Arteries of the Heart, by F. Charlewood Turner, M.D. 13. Abnormal Ureters, by W. Stephenson Richmond.

Essay on the Experiences and Opinions of John Howard on the Preservation and Improvement of the Health of the Inmates of Schools, Prisons, Workhouses, Hospitals, and other Public Institutions, as far as Health is affected by Structural Arrangements relating to Supplies of Air, Water, Drainage, &c. By R. D. R. SWEETING. Pp. 96. London: Baillière and Co. 1884.—This essay, which gained the Howard Medal of the Statistical Society and a prize of £20, contains, in a condensed form, the reports made by Howard on the sanitary condition of the various public institutions which he visited, at home and abroad, with his recommendations respecting their construction and management. It shows clearly how far ahead he was of the times in which he lived, and to what an extent he anticipated, in his recommendations, the measures which are now held by the best authorities to be essential to the preservation of public health. It brings him before us as a philosopher, a philanthropist, a social reformer, a statistician of no mean order, and an able, clear-headed sanitary pioneer.

New Inventions.

APPARATUS FOR REMOVING FALSE MEMBRANE FROM THE TRACHEA.

THE sad death and self-sacrifice of Dr. Rabbeth was clearly owing to the absence, at hand, of some efficient mechanical appliance for extracting the diphtheritic membrane from the trachea. It is now nearly nine years since I first made use of the aspirator for removing from the trachea inflammatory products threatening to cause suffocation, but finding the utility of the aspirator greatly interfered with, owing to the air being drawn into the trachea by the side of the suction tube, and thus destroying the vacuum, I devised the apparatus figured in the accompanying woodcut. It consists of a hollow piece of vulcanite, about an inch long, passed through the centre of a piece of wash-leather, or what is better, a thin piece of Dr. Scott Alison's impermeable lambskin, about six inches square, which is then tied to a groove (*a*) about a quarter of an inch wide, situated at one end of the piece of vulcanite. The hole through the piece of vulcanite is made a little smaller than the suction tube of the pneumatic aspirator which it surrounds, so that, although the vulcanite can be easily moved along the tubing when the latter is diminished in circumference by stretching, it nevertheless grasps the tubing, when not extended, sufficiently to prevent slipping. Without the piece of vulcanite the wash-leather could not be tied sufficiently tightly to the suction tube to prevent air passing between them and yet allow the position of the wash-leather, as regards its distance from the end of the suction tube, to be readily changed. To apply the apparatus, wet the wash-leather, and as the suction tube has been inserted into the tracheotomy tube or trachea, as the case may be, spread out the wash-leather over the neck of the patient, to prevent all entrance of air except through the mouth, and then turn the tap of the aspirator. By preventing air from entering the tracheotomy tube from without, the full power of the aspirator is available for extracting whatever substance may be in the trachea; but the suction power must of course be regulated as circumstances require. Although the diphtheritic membrane is rarely carried into the exhausted bottle, it is drawn sufficiently far into the suction tube to allow of its being pulled out of the trachea when the suction tube is withdrawn. I keep in my tracheotomy case a piece of indiarubber tubing already passed through the vulcanite with wash-leather attached, so that the wetting of the leather and slipping one end of the tubing over the suction nozzle of the aspirator, which is all that has to be done to make it ready for use, is the work of only a few moments. In the absence of an aspirator, a large syringe might be used to create the suction power. As all rubber goods when not in constant use are liable to perish quickly, the tubing should be seen to several times a year. Dr. Scott Alison's impermeable lambskin consists of wash-leather covered on one side with a thin layer of indiarubber. It is sold by Messrs. Ewen, 106, Jermyn-street, W.

Mansfield-street, W. T. MARK HOVELL.

ACADEMY OF MEDICINE IN IRELAND.

THE second annual meeting took place at the Royal College of Surgeons in Ireland last week, presided over by the President of the College. The office-bearers for the ensuing year were elected, but few changes taking place in the various sections. The Council had recommended a presentation of £100 to Mr. Thomson for his services as general secretary, but that gentleman very properly refused to accept it. The proposal last year caused a considerable amount of opposition, and it would have been in better taste if the Council had not sent a recommendation of the kind for the sanction of the Fellows. A resolution of Mr. Swanzy's was adopted, to the effect that it be referred to the General Council, with recommendation that the Academy should endeavour to encourage original research by grants or otherwise, and to report on the subject. The proposal that in future the election of Fellows should be made at general meetings of the Academy, and that all Fellows should the right of voting, was lost by four voters.

THE POLLUTION OF THE LEA.—At a well-attended public meeting held at Hackney on the 28th ult., a resolution declaring that nothing was feasible to secure the purity of the Lea short of an intercepting sewer to carry the sewage of Tottenham, Walthamstow, Leyton, and West Ham, after treatment, to the Thames at Barking, and that the Home Secretary be memorialised on the subject, was carried.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 8, 1884.

WITHOUT ceremony of any kind the most successful show which has been seen in this country since 1851 came to an end on the 30th ult. The grand total of visitors had reached 4,167,000, or an average of 27,000 per diem from May to November. The secret of the success was doubtless due to the breadth of the Exhibition, if we may use such a term, and to the fact that the articles displayed and the amusements provided were calculated to suit all tastes and to interest everybody, from the philosopher to the village housewife. If we are to have a continuance of such exhibitions (and this desirable project is entertained), it is of course essential that they should pay financially. Any lasting good which may be derived from an exhibition such as that which is just closed is (in this country, where voluntary effort takes the place of State endowment) contingent on financial success. When the guarantors are called upon to make good a deficit, we shall have seen the last Exhibition. The managers of the Health Exhibition did wisely to spare no effort to make the Exhibition attractive. Illuminated gardens, bands of music, concerts and restaurants, were the attractions which brought the crowd and paid the bill, and if a certain percentage of the visitors never succeeded in dragging themselves away from the sensuous pleasures of the gardens, no possible harm has been done. Some of the writers for the daily press seem to have been of the sensuous order, and because the pleasures of an open-air concert and a cigar have kept them from more serious studies, they seem inclined to pooh-pooh the whole affair, and to ridicule the idea of any permanent good resulting from the Exhibition. We do not share this view, but, on the contrary, believe that very few can have visited the Exhibition without deriving some benefit or instruction therefrom. If the Exhibition had its glittering side, it certainly had its serious side as well: and if no good results or lasting impressions remain, the fault lies with the public and not with the promoters. The fact is that while the many have been amused, the few have been instructed. There will be, we are told, twenty stout volumes as the literary outcome of the Exhibition, and this represents a large amount of serious work, produced at great cost.

The library, containing some 7000 volumes on Health and Education, has been very largely used during the summer, the number of readers showing a steady increase. The readers of THE LANCET do not require to be reminded of the Biological Laboratory, which we have been at great pains to reproduce as graphically as may be in our columns. The scientific lessons taught in this laboratory have been of undoubted value, and have succeeded in drawing public attention to the study of bacteriology, which hitherto has been too much neglected in this country. Of Lectures, Conferences, the Sanitary and Insanitary Houses, and of the various exhibits of scientific interest we say nothing, except that they were all at hand for those who had eyes and ears, and taught not a little when these were accompanied by intelligence.

The questions now arise, What is the surplus, and what is to be done with it? The second question is necessarily dependent on the first, and the destination of the surplus must clearly depend on its amount. That there will be a surplus seems certain, and we hope that it may be substantial, but it must not be forgotten that the expenses of the Exhibition have been enormous, and until the accounts are all rendered it is useless to speculate. The Executive Council is well qualified to advise the Prince of WALES as to the bestowal of the surplus funds. There is a rumour that efforts will be made to found a Central Institution for the Instruction of Sanitarians of all grades—an institution which will gather under its wing the various voluntary efforts made by different societies. Our readers will remember, however, that we recently urged with much earnestness that no use of the profits of this great Exhibition could be more satisfactory than to apply them to the creation and endowment of a biological or a bacteriological laboratory, wherein the nature and properties of germs might be investigated. This country has been lamentably behind other countries in this branch of investigation—notably behind France, Germany, and Italy. The admirable remarks of the Duke of BUCKINGHAM, or rather of the Executive Committee of which he is the spokesman, happily show that this discreditable defect in our State provisions is being realised by public men. After referring to the hygienic laboratories, biological and physical, as a leading feature of the Exhibition, his Grace said:—"The maintenance of the laboratories would ensure a means of sanitary research and teaching for the future which England has not had in the past. In these laboratories studies could be carried on and teaching could be given of a kind similar to that which is afforded by various foreign institutions which have been established in the interest of public health. These studies have a direct bearing on the relation of health problems which not only affect the well-being of communities, but exercise an important influence on agricultural and commercial interests." We cannot doubt that his Royal Highness will heartily adopt the views thus foreshadowed for his approval, which we trust to see enforced in the further report promised by the Committee. The Exhibition has been a success as a show and as a financial undertaking. But it will live much more honourably in history if it is associated with a new and permanent impulse to sanitary science. It may seem monstrous that the happiness and prosperity of great nations should be at the mercy of bacteria, beings which, judged by their weight and size, are quite contemptible; but we have to do with facts, and it looks certainly like a fact that such is the case. At any rate, the truth has to be found out. And if this kingdom, which has done so much in the way of leading sanitary science, is not to sink into a third-rate position amongst enlightened nations, it is high time to be showing some sign. We have competent men. We hold the country in which cholera has its seat and home. We practically hold the gate through which it passes thence to Europe to work such vast destruction and disaster as we have seen this year in France and Italy. On every ground we ought to be foremost in the

Digitized by Google

investigation of great Health questions. The Exhibition itself may have somewhat disappointed those distinguished foreigners who came looking for light on deep questions of sanitation. But if it ends in the establishment of a Hygienic Laboratory, with well-equipped apparatus, and with liberal endowments for those who undertake research, the country of JENNER and CEELY, of PARKES and SNOW, and of SIMON and LISTER will not need to fear comparison or competition with the countries of PASTEUR or of KOCH, or of TOMMASI CRUDELI.

We again venture to express the hope that our great Hospitals, which exist to restore the lost health of the poor, may not be forgotten by the Committee in the distribution of any surplus. These institutions are inexpressibly useful, and at the present time extremely in need of help.

ONE of the most cogent arguments on which the adversaries of the doctrine of the localisation of cerebral function base their opposition is drawn from the difference of symptoms which may be observed between a similar lesion in man and animals. This argument, which possesses no scientific value, has frequently been refuted. Nevertheless, some experimental physiologists weigh in the scales clinical observation against experiments on dogs, rabbits, pigeons, and frogs, and many physicians insufficiently grounded in the question still remain in doubt. To speak plainly there is no contradiction in the evidence. When physicians state that in man certain destructive lesions of the brain always give rise to permanent paralysis of the opposite side of the body, they merely formulate a law which is founded on a considerable number of regular and concordant observations, which cannot be diminished in value by any experimental observation. When, on the other hand, physiologists assert that in the rabbit or pigeon destruction of the cerebral hemisphere does not produce persistent paralysis of the members of the opposite side of the body, and when ocular demonstration is given of the fact, it would be contrary to all scientific logic to contest the statement under the plea that the results were different in man. The field of clinical observation and that of experimental pathology, however much they may lead to the same end, are distinctly separate and ununited. PITRES has contributed an article to the above effect in the *Journal de Médecine de Bordeaux* and has collated the main facts concerning secondary degenerations, which he intends to contribute in full to some forthcoming numbers of the *Archives de Physiologie*. In man the principles which govern the production and topographical distribution of degeneration of the pyramidal tracts as the result of partial destructive lesions of the brain may be stated in the three following propositions. Even very extensive destructive lesions of the "non-motor" regions of the cerebral hemispheres never give rise to secondary degenerations. Destructive lesions of the "motor" region, however limited in area, are always followed by secondary degeneration. The degenerations descend in the lower layer of the cerebral peduncle, in the pons, and into the anterior pyramids of the side opposite to the lesion, a course which accurately corresponds with the well-known path of the pyramidal tracts. In the spinal cord below the decussation of the pyramids the degeneration does not invariably occupy the same regions of the cord. Sometimes the pyramidal bundles pass down only in the opposite lateral column (TÜRCK, CHARCOT, BOUCHARD); sometimes they descend in the opposite lateral column and in the anterior column on the same side as the cerebral lesion; lastly, they may proceed downwards symmetrically in the two lateral columns (PITRES). In all cases the area of degeneration is relatively considerable in extent, and may be estimated at several square millimetres.

In dogs and cats destructive lesions of the occipital lobes do not bring about secondary degenerations of the spinal cord; but similar lesions of the convolutions bounding the crucial sulcus are followed by an appreciable degeneration, which occupies the middle and internal parts of the inferior aspect of the cerebral peduncle, pons, and anterior pyramid of the medulla oblongata on the same side as the cerebral lesion. In the spinal cord the degenerated band is very slender, and generally occupies the lateral column on the side opposite to the cerebral injury. Sometimes PITRES has found symmetrical alterations in the two lateral columns of the cord, but the inner portion of the anterior column has never been altered. In all cases the extent of the area of degeneration in the cord is much less than that of the corresponding area of sclerosis in the cerebral peduncle or pons. Proper allowance being made, the area of degeneration in the spinal cord of these carnivorous animals is relatively and absolutely much less than is found in man.

In rabbits and guinea-pigs destruction of the occipital lobes produces no secondary degeneration. Destruction of the excitable region of the cerebral cortex gives rise, on the contrary, to a descending degeneration, which is easily followed in the peduncle, pons, and anterior pyramid of the same side; but, contrary to what happens in the dog and the cat, the degeneration does not pass beyond the lower part of the medulla oblongata; no sclerosis occurs in the spinal cord.

In pigeons and fowls ablation of the whole of a cerebral hemisphere does not cause any sort of descending degeneration, either in the brain or spinal cord.

A comparison of the above facts leads to the conclusion that the anatomical communications connecting the brain with the spinal cord are not established as a uniform type throughout the vertebrata. In man, a great many of the fibres which start from the motor region of the cerebral cortex are prolonged directly into the spinal cord, consequently the direct cortico-medullary fibres are very numerous. In the dog and cat the greater part of the fibres which start from the excitable convolutions are arrested in the grey nuclei of the pons and medulla oblongata, so that the direct cortico-medullary fibres are relatively less abundant. In rabbits and guinea-pigs all the fibres which begin at the excitable areas cease at the protuberance and bulb; there are no direct cortico-medullary fibres. Finally, in birds the cerebral lobes are not united by distinct bundles to the subjacent parts of the neural axis; these animals have no pyramidal tracts,—or rather this tract, if it does exist, does not begin in the cerebral lobes properly so-called. Bearing these facts in mind confusion seems to pass away when we wish to know how it is that destructive lesions of the brain produce permanent and marked paralysis in man, slight and

Digitized by Google

transitory in the dog, diffuse and fugitive disturbances of motility in the rabbit, and no disorder of motion in birds.

A SOLITARY case of small-pox in Illinois, that of an immigrant arriving in Chicago in the eruptive stage of the disease, in November, 1879, led to a widespread epidemic throughout the State. The greatest intensity of the disease was in the winter of 1881–82, and the outbreak can only now be regarded as at an end. In the fifth annual report for the State an attempt is made to calculate the cost of the epidemic, reports having been sent in with a view to this. All districts did not report, but it is assumed that the cost per case was the same in the localities from which no news came as it was in the others. The actual cost of dealing with an individual case is first taken, and to this is added what are termed the constructive losses, which include losses to common carriers by interruption of travel and traffic, and to businesses of all kinds by panic, quarantine, &c. Taking the entire State except Chicago, it is estimated that the actual cost incurred in connexion with 2040 cases which were reported amounted to over $281,000,000, and that the constructive losses spread over 14,520 days reached over $3,339,000,000. In Chicago itself the same two items amount to nearly $783,000,000, and the expenses to the entire State from January 1st, 1881, to December 31st, 1883, during which period the disease prevailed as an epidemic, amount in all to close upon $4,404,000,000. This total sum does not include expenses for vaccination, which, in Chicago for example, is performed gratuitously; neither does it take account of the value of human life lost, time wasted, and a variety of speculative items often included in such estimates. In the face of such facts it is hardly surprising that prominence is given to the value of the order relating to compulsory vaccination as introduced into the State. It is certainly limited in its application to schools, but it is reported that whereas on the commencement of the epidemic schools were closed in very many instances, yet that they were reopened on the advice from the Board that enforcement of the vaccination was the only safeguard; and later on it appeared that in only two instances out of a total of 12,000 schools in the State was closure resorted to on account of small-pox.

ATTENTION has lately been directed to the fact that the money difficulties in which many hospitals are now involved are partly due to the too indiscriminate relief which has been afforded by them to persons whose social standing is much above the average position of out-patients. It would seem as if the hospital authorities, having their time occupied with the diagnosis and treatment of the sick who apply to them, do not care to weed out the social grades whose true place is outside the sphere of gratuitous practice; so those who apply are taken as they come. Applicants of the kind in question do not necessarily mean to deceive the hospital authorities as to their ability to pay a fee. Doubtless they do sometimes—as when they send their children, as they have been known to do, under the name and care of some poor dependent to benefit by superior professional skill, free of cost, at some public institution. In other cases they attend the hospital practitioner's clinic simply because they are more familiar with his official than with his private time and place of consultation. In either case they and theirs are out of place in the hospital waiting-room. Emergencies of course allow no rule but that of present necessity. After making every fair allowance and deduction, however, there still remains a number of non-indigent applicants for free relief, who should, in justice, be eliminated from the hospital *clientèle*, and advised to seek the services of a practitioner near their own homes, or, if they prefer it, to attach themselves to the ordinary practice of the hospital physician or surgeon.

The records of dispensary work could furnish instances of a similar, though more limited, misuse of public trust. Workmen's clubs, again, are notoriously unscrupulous in stretching their brotherly consideration to cover wide diversities of status and income. Well-to-do shopkeepers, master builders, and the like, swell the number of their *quasi*-artisan constituencies. How long shall medical men continue to countenance and support such needless benevolence? The measure of professional charity is surely full when they have applied themselves to meet the demands in sickness of the really poor. There is a limit to their encouragement of thrift on the part of those who have enough for daily wants and something over, and it must be evident that to carry charity to those who can and should contribute to it is to lessen the supply available for its proper objects.

The remedy for these abuses, we have seen, consists in the direct exclusion of all persons whose income fairly represents a position in the middle rank from the benefits primarily intended for the lower class of mechanics. Who shall apply this remedy? The rule that one should do for himself what he wishes well done applies here. The treatment of this social evil had probably best be left in the hands of the medical practitioner. The other officials of a hospital or dispensary, or the agents of a benevolent society, can render valuable assistance, but the personal earnestness and conscientiousness of members of our profession should chiefly be relied on to decide whether its generosity shall be the boon of the needy or the shrewd investment of some prosperous man of business.

Annotations.

"Ne quid nimis."

MR. GLADSTONE ON THE REPRESENTATION OF MEDICINE IN PARLIAMENT.

MR. GLADSTONE has caused the following answer to be sent to the Committee of the Association of Members of the Royal College of Surgeons who had desired the Parliamentary representation of registered medical practitioners:—

10, Downing-street, Whitehall, Oct. 29th.

SIR,—Mr. Gladstone has had the honour to receive the communication which you have made to him on behalf of the Committee of the Association of Members of the Royal College of Surgeons, urging that provision be made for the representation in Parliament of the medical practitioners of the United Kingdom. In reply, I am directed to say that Mr. Gladstone readily admits the title of the Committee to raise a question of this nature, but he cannot think that their particular proposition would commend itself to the judgment of Parliament. He would gladly welcome the presence of more members of the medical profession in the

Digitized by Google

House of Commons, but in his opinion this can only be secured by the means which are at present open to all other professions. I am to add that Mr. Gladstone is unable to admit the contention in your letter that other learned professions are directly represented in the Legislature.

I am, Sir, your obedient servant,
E. W. HAMILTON.

This reply, though very much what we expected, is not satisfactory. Mr. Gladstone denies the direct representation of the other learned professions in the Legislature. He will scarcely deny that they are both directly represented in the House of Lords. The Lord Chancellor is surely not an accident there; neither are the bishops there by chance or by any indirect system of representation. The Lord Chancellor represents Law, and the bishops represent the Clergy and the National Church. The great profession of Medicine has more to do with the happiness and welfare of the people than that of Law, and nearly as much as that of Divinity. Yet such is the defective nature of our Legislature that it is but slightly represented in the Lower House and not at all in the Upper. It is not congenial to medical men to fight the rough battles of the hustings. The weapons of their warfare are not fitted for that kind of strife. But none the less are they entitled to be recognised in every wise State by an honourable place in its Senate.

PANICS IN PUBLIC ASSEMBLIES.

WE have so repeatedly and at such length, from points of view special as well as general, discussed the subject of panics in public assemblies, that it is difficult to offer any suggestion that can claim notice on the score of newness. There is, however, more than sufficient food for thought in this topic, and, without dwelling on the details of the recent lamentable occurrence at Glasgow, or attempting to determine the exciting cause of the catastrophe, which is, indeed, *sub judice*, it may be worth while to offer a few observations on the matter as a whole. Panics will take place as long as assemblies are held, and without in the least abating anything of the remonstrance we, in common with our contemporaries, have from time to time addressed to local and central authorities against the neglect to *enforce* proper precautions, it must be conceded that, even if the assembly in which a panic occurs consisted of a dense concourse of people in the centre of an open plain, without buildings or rails, or anything whatever to prevent the crowd from dispersing, dire accidents would be sure to befall the innermost of the persons congregated, and deaths would probably ensue either from pressure, suffocation, or trampling. It is therefore useless and misleading to wholly blame the surroundings of a panic-stricken crowd for the commotion which occurs in it, or for the consequences which ensue when silly, or, for the moment, senseless, people rush madly on their own destruction. The real fault is in the average mind; and, unfortunately, the very dwelling upon these "accidents," and the word-picture painting of their horrors in the newspapers, inevitable and necessary as publicity must be deemed, are evils inasmuch as they aggravate the susceptibility to panic which, above all things, it is most desirable to reduce and relieve. If only reason could be retained, and weak-minded and excitable folk would not go stark raving mad the instant some fool or knave cries "Fire" in a public assembly, all would be well. No punishment is too great for the wanton scoundrel who raises a needless terror. He is worse than a murderer. Hanging is too good for such a criminal. No words can adequately express the indignation that must be felt against an offender of this class; but the fatuous and contemptible excitability of the majority of sight-seers is scarcely less abhorrent to common sense and humanity. Is life so very precious, is death—the inevitable—so appalling, that the poor mean fool must lose his wits and forget everything but his miserable lien on existence the moment this right of property seems to be assailed? If half a dozen savage dogs, or a few stalwart men with cart-whips, could be let loose on a panic-stricken assembly, the best possible treatment would be adopted. This is how the shrieking multitude ought to be reduced to order. We begin to think stern reproach should take the place of compassion for the victims of panic. Harm has been done, and is done, by laying too much stress on the need of special precautions. Let crowds be taught to take care of themselves. Let those who go to crowded assemblies of all sorts and conditions clearly understand that they go with their lives in their hands, and at their own sole risk; that they must shift for themselves, and if they behave like idiots they must take the consequences. This is the line of argument which strikes us as not merely politic but proper to the case. There is too much trusting to others, and to the provisions for safety which the managers of public assemblies ought to be compelled to make. It is nonsense, idle and worthless ignorance, to talk of the possibility of emptying a building in so many minutes or seconds. All such calculations are rendered useless and inapplicable the instant a panic occurs. A doorway out of which ten men might walk abreast would not suffice for the safety of even one hundred persons if they all rushed to it at once. The *reductio ad absurdum* is made by almost every "accident." The wider the exit the greater the rush, and the greater the rush the greater the accident, without regard to the structure or the way of exit. If a thousand persons can be quietly got out of any building in two minutes, the whole thousand will be jammed together in trying to get out in half the proper time. It is the madness that causes the calamity, not the limitation of the means of exit, provided always that these are fairly adequate. Something must be done to secure immunity from panics, and still more needs to be done to induce or compel persons to act as sane creatures instead of lunatics in the face of danger. We would urge this subject on the consideration of members of our profession and the public generally. Lectures on the folly of panic might with advantage be delivered from time to time, and it would be well if a serious attempt were made in every city, town, and populous district to discipline crowds and to inculcate the great lesson of safety, which consists in the experience that cowardly craziness in the presence of real or supposed danger is alike discreditable to men, to women, and even to little children, who ought to be taught betimes that all *must* die, and that to run madly away from death is to surrender the claim to live, and to show that the gift of life has been unworthily bestowed, and is unmerited.

PEPTONISATION.

AN important contribution to the physiology of albumens has recently appeared from the pen of Herr Chandelon. It is well known that peroxide of hydrogen is decomposed with the evolution of oxygen in the presence of fibrin and organised tissue as well as of several metals and oxides; and it has generally been stated that this dissociation takes place without the albuminoids or metals undergoing any change. No evolution of oxygen occurs when other organic substances are brought into contact with the peroxide of hydrogen. Herr Chandelon suspected that in this latter case there might be a reaction, though it was not perceptible because the oxygen was used up in oxidising the organic matter. In order to test this suspicion, egg albumen was suspended in water and exposed to the action of nascent peroxide of hydrogen. At first sight there was no result, for neither leucin nor tyrosin was detected. Nevertheless, it was observed that the albumen had undergone some change, in that the volume of the precipitate produced by boiling the mixture gradually diminished, whilst the liquid after

Digitized by Google

separation of the coagulum by filtration gave upon treatment with alcohol a copious precipitate, which, upon being redissolved in water, gave all the reactions of an albuminoid substance. Further investigation left no doubt that the albumen had, partly at least, been converted into peptone; it was therefore of interest to study the reaction more closely, to isolate and identify the intermediate products. Herr Chandelon found that peroxide of hydrogen in the nascent state peptonises egg albumen, and peptonisation may be considered a phenomenon of hydration—an opinion that is supported by the formation of peptone from albumen by reagents capable of fixing water, such as dilute acids, alkalies, &c., and the reconversion of peptone into albumen by a dehydrating material like acetic anhydride. It is suggested that the albumen (anhydride) gives up an atom of oxygen to the peroxide (H_2O_2), just as oxide of silver does, and that the two groups that had been united by the oxygen then combine with two hydroxyls. The conversion takes place by the same process as in digestion with peptic ferments. The author puts forward the hypothesis that the digestive ferments promote digestion by the production of peroxide of hydrogen. These results appear to throw light upon some unexplained phenomena met with by M. Béchamp in his investigation on the constitution of albuminoids, and are in accord with the behaviour of the papaine ferment observed by M. Wurtz. It would be interesting to know if peptones so formed are devoid of the bitterness which is an objection in those formed under the influence of ordinary ferments.

THE LATE DR. RABBETH.

WE are glad to see that a meeting to perpetuate the memory of Dr. Rabbeth has been held at King's College. At King's College School, in the medical department of the college, and in the hospital, Dr. Rabbeth received his education and training; at the University of London he took his degree; and at the Royal Free Hospital he was in charge of the wards when he performed the heroic deed which caused his death. It is only meet, therefore, that the representatives of these various bodies should join his colleagues, fellow-students, and relatives in commemorating the brave manner in which he did his duty—and died. The committee which has been formed, under the presidency of the Archbishop of Canterbury, is so large and comprehensive that no distrust can be entertained as to the thoroughly loyal manner in which any funds entrusted to it will be administered. We feel sure that the profession and the public will not only be glad to subscribe willingly, and thus testify their admiration for so noble a self-sacrifice, but will be also thankful for having the means pointed out by which practical good to the sick poor may be associated with the memory of a lost medical hero.

DEADLY TOYS.

WE have again to call attention to the extremely dangerous nature of many of the playthings put into the hands of children. A boy aged five has recently died at St. Thomas's Hospital from injuries caused by swallowing a "puff-dart." While amusing himself with the toy, the child suddenly drew in his breath and the needle of the "puff-dart" passed into the air passages. The boy died at the end of a month with symptoms of dyspnœa. At the post-mortem examination, the needle, with the worsted attached, was found to be lodged in the lower part of the trachea and firmly wedged in the left bronchus; there was also very intense suppurative lobular pneumonia affecting the lower lobe of the left lung. This case adds one more to the long list of fatal accidents caused by dangerous toys. It is to be hoped that ere long the Legislature may be induced to deal with the subject.

SIR WILLIAM MURE MUIR, K.C.B., M.D.

ON Saturday last the life-size portrait in oils of the above-named lately retired eminent chief of the Army Medical Department was presented to Lady Muir, in the name of the officers of the medical staff serving in all parts of the British Empire. Owing to the much-regretted serious illness of Sir William Muir, it was found necessary to dispense with the deputation which it was intended should formally present the portrait, and the proceedings were therefore strictly private. The portrait, a three-quarter length, by Mr. W. R. Symonds, whose numerous exhibits at the Royal Academy have been so justly admired, is a most striking likeness, and elicited warm commendations as a work of art, not only from the recipient, but also from all who had seen it at Mr. Symonds' studio. The original picture (of which this portrait is a replica) is by the same artist, and adorns the walls of the medical staff mess at Netley, forming there not only a permanent memorial of Sir William Muir, but also a lasting testimony of the high appreciation by the officers of the medical staff of the pre-eminent services rendered by him to the Army Medical Department.

"SUSPECTED POISONING."

WITHIN the last few weeks Dr. Danford Thomas has had to adjourn inquests for the purpose of obtaining further evidence as to the cause of death in three cases of suspected poisoning. In the first of these, a woman named Flagg, aged sixty-six, died whilst under the treatment of Dr. W. H. Day. This gentleman was prepared to give a death certificate, but a sister of the deceased had suspicions, not well grounded as it transpired, that poison might have been administered. At the post-mortem examination the kidneys were found to be granular and wasted. There was double hydrothorax. The heart was greatly hypertrophied and dilated, and the pericardium was adherent to it. The stomach, which was empty, presented no signs of irritation or of corrosion. The persistent vomiting from which the deceased suffered thus received a sufficient explanation. In the second case, Sarah Hickmott, aged twenty-six, died after a few days' illness, and immediately after she had aborted, although there had been no excessive hæmorrhage. Mr. Hunter of Clerkenwell was sent for, and on his arrival found the woman dead. The coroner ordered an inquiry on the information that criminal abortion might have been procured by the administration of some drug. An exhaustive chemical analysis of the contents of the stomach and of some powders and mixtures taken from the house of the deceased was made, but with negative results. The post-mortem evidence was unsatisfactory on account of the advanced state of decomposition of the organs. In fact, it was stated that the features were scarcely recognisable thirty-six hours after death. Unfortunately no urine was obtained, and so the question of albuminuria complicating pregnancy remained unsolved. That this explanation was probably the correct one, however, is supported by the fact that the deceased had frequently complained of severe and persistent headache. It may be noted that the liver and other organs were so soft that poisoning by phosphorus suggested itself. The analysis proved, however, that this was not the case. The difficulty in arriving at a conclusion was increased by the death having taken place without anyone witnessing it. In the third instance, Helen Dickenson, aged thirty, was found in bed quite insensible, and in a dying condition. It was surmised that she might have committed suicide. At the first autopsy certain signs were observed in the stomach and mouth which the medical man who conducted it held to be consistent with irritant poisoning. He also found three dark round bodies in the stomach which in external appear-

Digitized by Google

ance resembled pills, and for which, in fact, he mistook them. A further examination led to the conclusion that the death must have been due to asphyxia; that there were no signs of organic disease of the internal organs sufficient to account for the fatal issue; and, lastly, that the supposed pills were grocer's currants. An analysis of the contents of the stomach showed the absence of cyanide of potassium, the only poison likely to account for death under all the known circumstances. It was elicited that the deceased had been treated for "fainting fits." There seems little reason to doubt that these "fainting fits" were attacks of petit mal, and that death occurred on the accession of the first seizure with clonic spasms.

ANTISEPTIC TREATMENT OF WOUNDS BY DRY AND INFREQUENT DRESSINGS.

DR. FRANCIS J. SHEPHERD has gone far towards reconciling apparently conflicting systems of wound treatment in the title which he has selected for a clinical lecture at the Montreal General Hospital, just reprinted from the *Canada Medical and Surgical Journal*. Rendering full justice to Sir Joseph Lister for having revolutionised wound treatment and rendered operations, once formidable and dangerous, comparatively safe, Dr. Shepherd announces himself a strong advocate for the system of dry and infrequent dressings of wounds advocated by Mr. Sampson Gamgee of Birmingham. The title of his lecture is justified by the use he makes of mercuric bichloride (1 in 1000), carbolic acid (1 in 20), for cleansing sponges, and carbolised catgut for ligatures and sutures. He sprinkles iodoform on his absorbent pads, and immobilises by means of pasteboard splints, made pliable by dipping in hot water. Dr. Shepherd gives an account of seventeen amputations without a death, and of eighty-six other operations with two deaths—one after excision of the tongue, from gangrene of the lung following erysipelas, and one from shock after ovariotomy. "Many of you," remarks the Canadian surgeon to his clinical class, "after you receive your degrees, will practise in country or other places where it will be difficult or impossible to carry out the elaborate ritual of Listerism in all its entirety. In dry dressing, however, you have a method of wound treatment that may be employed with as much success, and the materials for which may be carried in your breast pocket."

"LANCING THE GUMS."

A GREAT surprise gradually made itself apparent on Monday last to the Fellows of the Medical Society of London, when it became clear that the whole of the evening would be devoted to the discussion of so apparently trivial a subject as "lancing the gums." Elsewhere our readers may gather the opinions of the several gentlemen who joined in the debate. The Society was certainly indebted to Mr. Edmund Owen for the opening of so successful a discussion. The subject appears to us to be one eminently fitted for treatment by the logical method. And, first, what are the facts? At the outset it will be seen that we are anything but sure of our ground. No one will question the statement that some infants have ceased to cry and have returned to a quiet state of mind and body after the application of the gum lancet. That proposition is beyond dispute. But who can tell how many infants have continued to suffer after the free use of the lancet to the gums? It was, has been, and no doubt will be, asserted that convulsions, diarrhœa, and bronchitis are at times caused by the irritation of dentition. We do not deny that such may be the case. Of the fact that diarrhœa does occur during the period of the first dentition there is of course no doubt; and the same may be said of many other diseases. Granting the association to be so frequent that it calls for special notice, what views may be held on the connexion? The diarrhœa *may* cause the irritation about the gums and teeth; the irritation of the latter *may* set up the diarrhœa; or both diarrhœa and dental disturbance *may* be dependent upon some cause in the immediate background. Such are the possibilities. All the hypotheses may be right, and any particular instance may be best explained by one or other supposition.

THE SURGICAL STAFF OF THE HUDDERSFIELD INFIRMARY.

CONSIDERABLE dissatisfaction has been expressed by the honorary surgical staff of the Huddersfield Infirmary at the action of the Monthly Board of that institution in deciding, in addition to filling up the vacancy caused by the recent death of Mr. Brewer, upon the election of another full surgeon. Considering that the average number of in-patients during last year was eighty-two, and the total number of out-patients 5494, and that to meet the wants of these patients a staff of two physicians, five surgeons, and three fully qualified house-surgeons exists, we are of opinion that, judging from the facts as they have been represented to us, there is good ground for the dissatisfaction to which we have alluded. It is well known that persons who are fully able to pay the ordinary fee for professional advice are in the habit of procuring gratuitous medical relief at the infirmary, and assuredly an increase in the staff will not tend to check this abuse; again, by lessening the number of cases under each surgeon's care this proposed increase will diminish his chance of gaining experience, and thus tend to impair the ultimate efficiency of the institution. The honorary staff, with a few of the governors, have summoned a formal meeting of the subscribers to consider the action of the Board in thus slighting and ignoring the opinion and wishes of the professional staff, and we trust that as the result of the discussion wiser counsels may prevail.

STRAIGHTENING CROOKED NOSES.

DR. JOHN B. ROBERTS recently showed a patient to the Philadelphia County Medical Society upon whom he had practised a new operation for straightening a deformed nose. In this instance the end of the nose was bent over to the right. Dr. Roberts first passed a scalpel into the right nasal fossa, and divided the cartilaginous septum from above downwards and forwards; he then transfixed the upper segment of the septum with a pin, also passed in from the right nostril, bent it over into the straight line, and fixed its point far back in the left side of the cartilaginous septum. The left lateral cartilage was separated from the bone by subcutaneous section, and pinned over in a similar fashion. The pins were to be left in place for three weeks. Dr. Roberts stated that this operation had yielded him good results, and it had the great advantage of avoiding the use of cumbrous or unsightly apparatus.

DISORDERS MISTAKEN FOR HYDROPHOBIA.

A PAPER which was read before the Medical Society of the State of Pennsylvania during the present year is worthy of notice on at least two good grounds. The author, Dr. Dulles, has succeeded in giving a wide application to the group of symptoms which goes by the name of hydrophobia. It will perhaps be readily conceded that many diseases are characterised by the same symptoms though the mode of arrangement of the symptoms unquestionably varies widely. To recognise in a thorough manner the fact that medicine has its alphabet of symptoms, and that any disease must be constructed of the letters in this alphabet, is more than half the battle on the high road to a scientific understanding of medicine. Let the full extent of these propositions be under-

Digitized by Google

stood, and dogmatism in scientific medicine must vanish. Admit, for example, that a disturbance of a transitory nature in the alimentary canal may give rise to the same and an equal number of symptoms as a cerebral tumour, and we believe that the goal of open-mindedness is reached. We do not assert that a differential diagnosis is impossible in the majority of cases; but that is not the question. What we should like to see more often than is the custom is the discussion of the diagnosis of cases on the basis of their elemental facts. This thorough dissection of symptoms has virtually been performed by Dr. Dulles in regard to hydrophobia. Another point of the paper which is deserving of commendation is the wealth of reference to the literature of rabies. There are, in this essay, no less than 300 apparently accurate references bearing directly on the subject.

A SCANDAL IN BERLIN UNIVERSITY.

PHILOSOPHY not seldom forgets to don the worldly robe of social tact. A neat little specimen of this general truth is now being exhibited to the Berlin University, and indirectly, to the world at large. Everyone familiar with science has heard the name of Du Bois Reymond, and nobody knows Dr. Schweninger. This sentence probably contains the pith and marrow of the pretty little scandal which is going the round of the German press. Dr. Schweninger enjoys the proud distinction of having reduced the corpulence of the Chancellor of Germany; for this merit he was made an Extraordinary Professor in the University of Berlin, where Du Bois Reymond has long lived in fame. The honour done to the reducer of the Chancellor's growing obesity did not greatly please the reducer's new colleagues. It appears that Dr. Schweninger left cards the other day at the residence of the Rector Magnificus, who showed his sense of the compliment thus paid him by returning them to their owner. A challenge was the result. Du Bois Reymond does not fight, and told his would-be opponent so. And thus a welcome subject for tattle has been furnished to the gossips by those who sit in academic furs and purple.

CRIME OR MADNESS.

WE are accustomed to see on the stage spectacles in which the villain of the piece is represented as wrecking a railway train by wilfully placing some obstruction on the rails. It is a serious question whether such scenes, "thrilling" as they may be, ought to be enacted for the public amusement. Certain forms of mental disease are known to be mimetic, and there seems to be reason to suppose that in one case at least a morbid mind has been so influenced as to perpetrate what, if it were not madness, would be an atrocious crime. Ex-captain Charles Newton Biggs is clearly a person who ought to be taken care of for more than one year, though that may prove long enough to develop and demonstrate his insanity. If he was not a lunatic, he would be a criminal of the worst possible class, much too dangerous to be again trusted at large.

FORGED FOREIGN DEGREES.

IT is an unpleasant fact that no less than two instances of an attempt to palm off forged Degrees of medicine of Vienna on the Faculty of Physicians and Surgeons of Glasgow were brought under the notice of the Medical Council at its recent meeting. These cases were referred to the Executive Committee for preparation for the consideration of the Council at its next meeting, and must therefore be considered *sub judice*. It is gratifying to know that in neither case was the culprit a registered medical man, though in one case he was a registered medical student. Henceforth we shall have to be on our guard against forged degrees as well as against bogus ones.

TYPHUS IN MANCHESTER.

AT a meeting of the Board of Guardians of the Chorlton Union attention was drawn to the prevalence of typhus in Manchester, part of the city being within the Chorlton Union. The disease commenced in August last, and since then thirty-four cases have been removed to the workhouse infectious wards, three have been sent to the Monsall Hospital, and five deaths have taken place. The disease still prevails, and a committee has been appointed to deal with the question of providing additional means of isolation. The outbreak has appeard in some of the worst localities in Chorlton-on-Medlock; the property being one which is generally condemned as a hot-bed of disease, and as unfit for human habitation. Indeed, pressure is about to be brought to bear upon the Manchester Corporation to purchase it and to convert it into an open playground, a plan which would afford a breathing space much needed in that portion of the city. It is to be hoped that very stringent measures of isolation, cleansing, and disinfection, will be adopted by the sanitary authority to get rid of the disease at the earliest possible moment, for the appearance of typhus at the onset of the winter in some of the worst portions of such a city as Manchester cannot be regarded without serious apprehension. Fortunately for the city the system of compulsory notification is in force.

IMPORTATION OF RAGS.

THE Local Government Board have extended the order forbidding the importation of rags from France and Italy until the close of the present year. The order forbidding the entrance of rags from Spain has been allowed to lapse. Rag importers are complaining greatly of the unequal working of these orders: for instance, in London the medical officer of health is carrying them out very strictly, no rags having been admitted for some time; while at other ports, notably Southampton, rags are freely admitted. Within the last fortnight no less than five or six consignments have been brought from St. Malo and Havre by the steamers of the London and South-Western Railway. Whatever may be the value of these orders from a public health point of view, it is certainly not right that they should be allowed to encourage trade at one port to the obvious injury of another. Naturally enough, the rag trade is slowly leaving London for Southampton.

PACINI'S MANUSCRIPTS.

THE Italian Education Minister is negotiating with Professor Pacini's heirs for the purchase of that pathologist's numerous and very important manuscripts. These include a diary kept by Pacini during several years of diligent experimental research. In the latter will be found a report, with almost daily entries, of cases during the cholera epidemic in Florence in 1855. The drawings of microbes were made with his own hand, after observations with a powerful microscope expresely constructed for the work.

FLOGGING GARROTERS.

IT would be a false and cruel philanthropy which could complain of the punishment administered by flogging to a man in gaol, on Saturday, for garroting with robbery. Hard labour is for a powerful man like the culprit in question a not excessive use of the strength which he possesses. Prison fare is sufficiently liberal to afford nourishment probably more wholesome, and more regularly obtained, than that which his habits out of gaol allow him to procure. It is somewhat difficult to see, therefore, how either of the latter penalties can act as a deterrent, though for a time it is necessarily a preventive, of

Digitized by Google

crime. The fear which the lash almost invariably awakens in offenders of this class, a fear proportionate to the pain of flogging, but in excess of any after-effects, is in itself a guarantee that we have always at hand at least one simple, effectual, and relatively safe protective against a most cowardly and dangerous form of assault.

"CYCLING."

IN our leader of last week on this question we drew attention to some of the more salient features of the controversy that has lately been carried on in these columns, and attempted to show what in our opinion were the possible and probable drawbacks and advantages of cycling as regards its influence on the maintenance of health in those who availed themselves of this mode of travelling. A letter, dated Oct. 27th, from Dr. Strahan, who strenuously opposes the practice, or rather excessive indulgence in it, deals with some of the facts bearing upon the occurrence and extent of "perineal pressure" and concussion of the spine. We have little to add to what has already been set forth. There can be no manner of doubt that evil consequences may ensue from indiscretion in this as in other pursuits of business and pleasure. Nevertheless, we maintain that it is quite within the reach of mechanical skill to fashion an instrument that shall minimise the danger arising from pressure on the urethra and jolting of the body. Moreover, it behoves us to consider the collective gain of the many while discussing the misfortunes of the few; and we hold that were cycling, even with its present attendant disadvantages, to be altogether discontinued, the public would be robbed of a means of usefulness and enjoyment that it would be difficult to replace.

TYPHOID FEVER IN SOUTH AUSTRALIA.

THE tenth report of the Central Board of Health of South Australia draws attention to the continued prevalence of typhoid fever in various parts of the colony. The cases of this disease appear to be spread over a wide area; and the Board, whilst fully recognising the importance of the discoveries which have been made by our central sanitary authority in England as to the association of this disease with varying, and often obscure, conditions of excremental poisoning, are obliged to admit that it has been impossible hitherto to trace the cases to their origin. It is, however, admitted that the investigations of the sort required cannot be satisfactory except as the result of long and patient work on the part of those employed, and it is clear that no such work has yet been carried out. A system of investigation has, however, now been commenced through the agency of officers of health and others, and it is hoped that important information may be forthcoming. There seems still need for some such skilled supervision of the work as is carried out in this country by the staff of medical inspectors whose reports are evidently valued in the colony.

FIRST "BOWMAN LECTURE."

THE first "Bowman Lecture" will be delivered at the meeting of the Ophthalmological Society on Thursday, the 13th inst., at 11, Chandos-street, at 9 P.M., by Mr. Jonathan Hutchinson, F.R.S. The subject is to be "Diseases of the Eye which appear to be in connexion with Gout."

THE APOTHECARIES' SOCIETY OF LONDON.

THE Court of Assistants of the Society, on the recommendation of, and in conjunction with, the Court of Examiners, has decided that on and after January 8th, 1885, it will not grant its licence to anyone who has not passed an examination in Surgery either at the Hall or else

DEATH OF THE RIGHT HON. HENRY FAWCETT.

THE death is announced of the Right Hon. Henry Fawcett, the Postmaster-General, which took place on the 6th inst., from congestion of the lungs. The right hon. gentleman was in his fifty-first year.

VICTORIA UNIVERSITY.

AT a meeting held on Wednesday, it was resolved that the Court, having considered a report from the Council, accepts the application of University College, Liverpool, to be admitted as a college in the University.

MR. VANDERBILT having recently made a donation of a considerable sum to the College of Physicians and Surgeons of New York, land has been selected on which to build a new home for the College. The site, which is a little over 350 feet in length and 200 feet in width, is in close proximity to the Roosevelt Hospital. Access to the other hospitals in the city is afforded by the West Side Elevated and the Belt Surface Railways. The extent of land now in possession of the College is much more than is needed for immediate building purposes, but it is reasonable to suppose that requirements which are not foreseen to-day will in the course of time arise, and the College will then be able to add new departments or increase the old ones, as may be required.

THE trial of Fleet and others *versus* the Managers of the Metropolitan Asylum District is now in progress, and even in its earliest stages it is evident that some very complicated questions, such as the meaning which properly attaches to the word "convalescent," and the admissiblity of evidence as to the influence of other small-pox hospitals, are certain to arise. It is to be hoped that some authoritative decision will be come to which will place the question of the isolation of small-pox cases on a footing which, whilst satisfactory to the interests of those attacked, will also have regard to those of the surrounding community.

ON the 30th ult. a deputation waited upon the St. Pancras Board of Guardians to protest against the project of the Metropolitan Asylums Board to pull down the various pavilions comprising the present small-pox hospital at Hampstead and the proposal to erect a large and permanent establishment of a similar description. The guardians unanimously adopted a resolution calling upon the members representing the parish at the Asylums Board to use all the influence in their power with the managers to effect the entire removal of the hospital to a more suitable site.

AT the Leeds School of Medicine, during the present winter session, Dr. Clifford Allbutt, Mr. Wheelhouse, and Mr. T. Pridgin Teale will each deliver three clinical lectures. The above-named gentlemen have relinquished active service in the Leeds Medical School and the Leeds Infirmary, but by giving these lectures, at which the attendance of medical practitioners as well as students is invited, they show their continued interest in the school under its new conditions.

AT the last weekly meeting of the London School Board, the discussion on the over-pressure question was resumed, with the object of deciding whether a special committee should be appointed to inquire into the allegations of Dr. Crichton Browne, or whether the matter should be referred to the School Management Committee. No decision was arrived at, and the discussion was again adjourned.

MR. EDWARD STANFORD, of Charing-cross, has just issued an excellent large scale map of the Nile from Dongola to Khartoum.

Digitized by Google

AN inquest was held on the 30th ult. at Guy's Hospital on the body of a man who was locked up by the police at 11 P.M. on the 26th ult. for being drunk and incapable, and who was discovered insensible in the cell at 4 A.M. on the 27th, dying before he could be got to the hospital. Medical evidence showed that death was due to fracture of the skull, and the jury returned a verdict of "accidental death."

WE hear with regret of the death of Mr. H. M. W. Macdonald, L.R.C.P. Edin., on the 3rd inst. It would seem that the deceased gentleman had resolved to inhale chloroform for the purpose of having a carious tooth extracted, and that during the operation the pulse ceased, and death ensued.

THE Professor of Chemistry at University College, Liverpool, reporting on three samples of the Windermere water forwarded to him, states that though hardly fit for drinking, yet there appears to be no reason why it should not be employed for household purposes in general.

A MEETING of the Association of Fellows of the Royal College of Surgeons will be held at the rooms of the Medical Society of London, Chandos-street, Cavendish-square, on Saturday, Nov. 8th, at 4 o'clock.

THE Right Hon. W. E. Forster, M.P. (late Lord Rector of the University), is to preside at the next dinner of the Aberdeen University Club, London, to be held at the Holborn Restaurant, on Wednesday, November 19th.

DR. YELVERTON PEARSON has been appointed by Her Majesty, through the Lord Lieutenant, to the post of Professor of Materia Medica in the Queen's College, Cork.

DR. TOMMASI CRUDELI ON MALARIOUS COUNTRIES, AND THEIR RECLAMATION.

(*Concluded from page 798.*)

ATMOSPHERIC amelioration has also been effected in the new quarter of Rome, where, especially in the Quirinal and Esquiline, formerly subject to malaria, the buildings and the pavements have excluded the soil from contact with the air, which, however, evokes the malaria whenever such exclusion is interrupted by excavation. At best, therefore, this atmospheric amelioration is only suspensive, and possible only on land where building or pasturage or continuous submersion is practicable. Permanent atmospheric amelioration—that is, such modification of the composition of the malarious soil as would render it barren in respect of malaria while conserving its power of useful production—is a result which, as men of science, we must confess ourselves impotent to effect; while as practical hygienists we may admit it as probable that the combination of hydraulic amelioration with culture of the malarious soil has in some cases modified the composition of this latter so as to make it barren in respect of malaria. But we do not know how this has been brought about, nor can we reproduce it at will. The ameliorations effected in antiquity by centuries of drainage and cultivation combined were suspensive merely, because the moment the scene of operation was abandoned it relapsed into its previous malarious condition. The Campagna of Rome seemed reduced to permanent salubrity under the Antonines; but on the fall of the empire the malaria reappeared, just as if centuries of cultivation had never been.

Indeed, no one can say *a priori* whether the cultivation of a malarious soil will render it salubrious or not. There are instances even where such cultivation augments the malaria. At first this always happens; the disturbance of the malarious soil with the plough or the spade throws an increased surface into contact with the air and so the poison develops. Often this first effect of cultivation lessens in time, and sometimes disappears. Not seldom it obstinately persists, cases having even occurred where cultivation has had to be abandoned in despair, and the soil hastily recoated with as compact a meadow covering as possible to make it tolerably inhabitable.

Still, it is well to try, on favourable opportunities, whether it is possible to augment the efficacy of hydraulic or of hydraulico-atmospheric improvement by means of cultivation. A thousand economic reasons counsel the trial though the issue be problematical. Not only courage to face the problem is necessary, however, but some assurance of its solubility, otherwise we are apt to find ourselves in a vicious circle; on the one hand, cultivation cannot be entered upon unless we can secure the uninterrupted presence of cultivators on the spot all the year round; on the other, the cultivators cannot remain on the spot during the hot season and live. There is but one way of escape from this dilemma—to wit, that of augmenting the specific resisting power of the human organism to the attacks of malaria.

Dr. Tommasi Crudeli has devoted assiduous labour in these latter years to find the means of promoting this resisting power. He does not believe that individual acclimatisation, in respect of malaria, is or has ever been possible. The infection is a progressive one, as indefinite in duration as that of syphilis, one attack sometimes sufficing to ruin the constitution for life. An acclimatisation, not individual, but collective—that is, the acclimatisation of a race—was possible in the past, when specific remedies against malarious infection were unknown, and even later, when the application of these remedies was very limited. The acclimatisation of a human race, then, happened by means of a natural selection (*cernita*), wrought by the malaria itself, which, in succeeding generations, carried away well nigh, without impediment, all those whose specific resisting power was weak, while sparing those whose resisting power was strong. The former, according to the Greco-Italian myth, were the human victims destined to pacify the demon who opposed their occupation of the territory in which it had reigned till then as absolute sovereign. The latter became the founders of the colonising race, in which, with every fresh generation, were produced new selections (*cernite*) useful for the social body, so that the collective resisting power of the race rose progressively. In our days such a selection may happen in human savage races (and it happens in the breeds of oxen and horses imported into malarious countries), but it has become impossible in human civilised races. Thanks to the specific remedies at our command, the use of which is so general, we preserve the lives of many whose specific resisting power is feeble, and who, after being cured, beget children who have even less than they; so that after a series of generations there is produced in malarious countries a physical deterioration of the human race instead of that useful selection (*cernita*) which took place in past centuries.

External nature cannot be counted on for augmenting the specific resisting power of human societies to attacks of malaria. Art must be resorted to—the daily exhibition of the salts of quinine, of the alkaline salicylates, of tincture of eucalyptus, having all had their turn. Dr. Tommasi Crudeli has found arsenious acid most efficacious, particularly as preventing recurrence of the fever. In 1880 he first employed it systematically in the Roman Campagna. Among its recommendations are—the longer duration of its antimalarial action, its low price, its beneficial influence on nutrition, and the facility with which it was taken, even by children. In the following year arsenic, in the solid form, was, at his instance, exhibited to a very large *clientèle*, including the tenants of farms and the *employés* of the Roman and South Italian railways, and at the close of 1883 the results have been these:—When the arsenic has been administered some weeks before the malaria season sets in, and when its administration has been continued regularly throughout this season, the human organism best resists the attacks of the fever. In some cases an absolute immunity, in others a relative immunity, from malaria was attained. These latter cases are sometimes attacked by the fever, but even in the worst localities it never becomes pernicious (*pernicious*), and they get over it with a little quinine. Last year, for example, Dr. Ricchi experimented on seventy-eight individuals in the Ferind district where malaria is endemic.

Digitized by Google

He divided them into two sections, one only of which was subjected to the prophylactic treatment by means of arsenic. At the end of the febrile season it was found that while of the half consisting of those who had had no prophylactic treatment many suffered severely from malaria, thirty-six of those who had been under the course of arsenic remained entirely free from it, and the other three had had slight attacks, of which they cured themselves with a little quinine without calling in the physician at all.

These results are all the more encouraging, as the general health of those subjected to the course of arsenic is always greatly improved. Increase of weight and diminution of the anæmia so common in malarious countries are invariably found at the end of it. Prudence, however, prescribes an accurate graduation of the doses, commencing with two milligrammes a day for adults and guarding against taking the arsenic on an empty stomach. On the other hand, the dose may by degrees be augmented to eight, ten, and twelve milligrammes a day for adults when the locality is very malarious, so regulating its administration as not to produce an accumulation of arsenic in the stomach.

The true scourge of malarious countries, however, is not so much the outbreak of the acute fever as the chronic malarious infection; this it is which decimates the family, deteriorates the race, saps the sources of life, and produces a slow and progressive anæmia. This infection resists too often all the known remedies, and is even aggravated by the prolonged use of quinine, which is apt to prove a veritable poison for the vaso-motor system. A most efficacious, and at the same time easily procurable, remedy was announced three years ago by Dr. Maglieri, who had found it in traditional use in some Italian families. It is a decoction of lemon prepared by cutting the fresh fruit, rind included, into thin slices, and boiling these in three tumblers of water, until the volume of the water is reduced to one-third. Then this is passed through a thin cloth (muslin will do), while squeezing powerfully the residue of the lemon. After cooling for some hours, let it be drunk fasting. Among all the popular remedies for malaria fever this, says Dr. Tommasi Crudeli, is the most efficacious, and may be employed with advantage even in acute fevers. It seems, however, to have a specific action of great utility in chronic malaria infections which have resisted all remedies known to medicine. It has been tried on an extended scale, not only by Dr. Tommasi Crudeli, but by Dr. Pietro Cervello of Palermo, by Dr. Oreste Ferraresi of Rome, and by Dr. Giuseppe Mascagni of Arezzo, with the most gratifying results. It costs next to nothing—a very important consideration in Italy; it conquers the most stubborn fevers, and at the same time it restores to the patient his appetite, strengthens the whole nutritive process, and rapidly rehabilitates the system.

In no disease more than in malaria ought we to take account of popular experience. It is this which has rescued us from the "palustral prejudice" of the medical schools, and has taught us to extinguish malaria under our feet instead of wasting time on preventing its imagined importation. Popular experience, moreover, has shown that malaria rises from the soil into the atmosphere vertically only to a very limited altitude, so that by living, or at least sleeping, above this limit we may keep exempt from its influence. In the malarious districts of Greece and in the Pomptine Marshes of Italy the people during the malarial season bivouac at night on platforms propped on poles five or six metres high, and so escape attack. Here and there in the Roman Campagna houses are, with the same object, perched on the top of ancient tombs which have vertical walls. The American-Indians when they pass the night in malarious localities sling their hammocks to the highest trees they can find, and the engineers of the Panama railway built shanties for their workmen, also in trees, and so preserved them from the nocturnal malaria. We ought *a priori* to reject no useful remedy or precaution simply because it originated with the people. In the question of soil reclamation, it is essential to find a means accessible to all cultivators, of whatever age or condition, which is capable of overcoming the chronic infections of malaria, and of removing its grave effects. Science not yet being in a position to guide us to the discovery of such an agent, we are forced to collect with all due care the facts which may conduce to the desired result by another way; and if the means thus indicated appear innocent we must put it zealously to the test, unimpeded by any false conception of the dignity of science.

THE PROGRESS OF CHOLERA.

THE satisfaction experienced by the very complete subsidence of cholera in the south of France, Italy, and in Spain is materially marred by the wider area over which the poison has spread itself during the past fortnight. At Yport, in Normandy, cases still arise; but apart from a rumour that in some village near Rouen a single death has occurred, there has been no diffusion of the disease. Nantes, however, in the adjoining province of Brittany, is now seriously attacked. Since October 24th there have been over thirty deaths there, and fresh cases are still arising. From the fact that the first known case occurred in an hotel, it is assumed that the outbreak was due to a distinct importation from the south. In Algiers cases are still occurring at Oran, and isolated attacks are also reported from the other extremity of the colony. This extension of the epidemic, with the onset of colder weather, by no means augurs favourably for the prospects next season; indeed, it will need an amount of energy which we almost despair of seeing exercised to get rid of all the foci of infection during the coming winter.

In view of this further diffusion of the disease fresh quarantine measures have been put into operation by various States, and the importation of rags into this country is still further prohibited until the end of the year. Amongst the places where stringent quarantine regulations have been freshly established is Gibraltar, and some surprise and indignation are expressed on the Continent that England, which professes to disbelieve in the efficacy of such measures, should countenance the imposition of so rigid a code in one of her own colonies.—

LUNACY IN IRELAND.

THE inspectors of lunatic asylums in Ireland have recently issued their thirty-third annual report. On January 1st, 1884, there were in lunatic asylums, and in workhouses 14,088 inmates, being an increase of 266 as compared with the preceding year. As regards district asylums alone, on the first day of this year there were 9542 insane persons, being an excess over that on a similar date in the preceding year. The discharged cured numbered 1079, relieved 372, unimproved 88, deaths 892, and escapes 2. These contributed a gross total of 2433, including the increase of 271 above referred to. The proportion under treatment in district asylums on the 1st of January last was about 1 to every 540 of the general population, males exceeding females by nearly 18 per cent. The proportion of cures to admissions is about 40 per cent., but the daily average under treatment 11 per cent. The mortality (892) was not beyond the general average. The district asylums during the past year were especially exempt from epidemics and diseases of an acute character, death in the vast majority of cases being referable to advanced age or to a pre-existing debility of constitution. The income amounted to £252,560, which included £4750 from paying patients and £5974 from garden and farm produce, while the expenditure was £209,267. The average outlay per head for the year was £22 16s. 5d. The inspectors, while bearing testimony to the good behaviour of the attendants in public asylums, regard the present remuneration of these subordinates as totally inadequate, considering the duties they have to perform. Practically speaking, the result of inadequate wages is unsatisfactory. Attendants soon become discontented, leave the service, and their places are filled by persons often quite uneducated, and who in turn on acquiring some experience seek a like engagement wherever they can obtain better pay. No doubt a retiring pension is recognised at the end of a certain number of years, but the scale on which it is calculated is so uncertain that few remain to benefit by it. The mentally afflicted in union workhouses amounted to 3726, an increase of fifteen, all being hopeless cases, comprising epileptics, congenital idiots, or persons utterly demented for a considerable period and advanced in years. Occasionally it has become necessary to remove chronic patients from workhouses to district asylums on their becoming violent or evincing dangerous tendencies; but, for the most part, on the subsidence of excitement, they are sent back, otherwise the asylums would speedily become congested, to the exclusion of urgent or curable cases.

FRENCH HEALTH RESORTS.

(From our Paris Correspondent.)

LA BOURBOULE; CLERMONT; VICHY; HAUTERIVE.

LA BOURBOULE being a comparatively new spa, I wished to consult some of the most recent works giving a description of the place before visiting it in person. "La Bourboule actuelle," a small treatise by Dr. Ad. Nicolas, rendered me great assistance, and I was obligingly conducted over the place by this *confrère*, who is one of the physicians of the place. From his book I learned that the origin of the term Bourboule is not, as is generally supposed, owing to the locality being muddy, but it is derived from the ancient word "borbola," which signifies "eau bouillante" or boiling water. From Mont Dore the road to La Bourboule follows the tortuous course of the Dordogne, and the place may be reached on horseback, diligence, or carriage in a little more than an hour. It is about four miles from Mont Dore and is situated in a valley at the foot of a granite rock which completely shelters it from the north and westerly winds. The valley of La Bourboule presents different aspects according as one reaches it from Mont Dore or from the plains. On arriving at the top of the valley from Mont Dore the traveller beholds before him a beautiful landscape. The valley, in the form of a spacious amphitheatre, is bounded on the north and west by mountains, the slopes of which are covered with forests of pine and beech. The town itself does not look very old, as most of the hotels and villas are of recent construction. La Bourboule is a valley compared with the neighbouring mountains, but a plateau of the second order compared with the plains. Its altitude is about 2776 feet, and its climate, compared with Mont Dore, is mild and uniform; so much so that it has been recommended as a safe sanatorium for phthisical patients in July, August, and September, as it has not the inconveniences of the too rarefied air of the mountains nor the damp windy climate of the lower valleys. There are two bathing establishments in the place, and the waters are described as being "hyperthermal" and "athermal." The baths are fitted up with all the modern appliances of hydrotherapy, and may well compare with any similar watering-place in Europe for their swimming-baths, salles d'inhalations, douches oculaires, nasales, auriculaires, pharyngiennes, anales, vaginales, &c. The temperature of the waters varies according to the height or distance of the springs (from 82° to 140° F.), and one may have a warm bath in these establishments without the aid of artificial heat. Besides the salles d'inhalations, which are used in common by a certain number of patients at a time, as at Mont Dore, arrangements have been made for the more fastidious to have their inhalations in their bathing-cabins, and by a rather ingenious process a spray is produced, so that they can have the benefit of the inhalation and bath at the same time. This mode of treatment is not open to the objection referred to in my letter of Sept. 6th, as regards the risks of infection or those resulting from the high temperature to which the patients are exposed at Mont Dore. The waters of La Bourboule are obtained from five different springs. Their composition is nearly all the same, but varying only in the degree of temperature and the proportion of the different elements of which they are composed. According to the latest analyses, they are described as being eminently arsenical, containing as much as 27 milligrammes of arsenic to the litre. They also contain a large proportion of the various chloride and bicarbonate salts, and a certain quantity of carbonic acid gas held in solution. As at most of the spas, the waters here are employed externally as well as internally, and are found useful in all cases in which arsenic and the above salts are indicated, such as general debility, from whatever cause, the various manifestations of scrofula, diseases of the skin and bones, affections of the respiratory organs, asthma, diabetes, intermittent fevers, &c. Rheumatic patients and delicate children are also benefited by these waters, and so are women suffering from chronic affections of the womb. Although the season officially begins in May, it is in July and August that the place is most frequented, and it extends even to the end of September, during which period the weather is most enjoyable. The treatment lasts from fifteen to forty days, according to the nature of the malady, and should be continued for about a month after returning home, and repeated at certain intervals twice or thrice during the year for periods ranging from twenty to thirty-five days each time. This is easily done with these waters, as they keep well in bottles without undergoing any alteration or losing any of their distinctive properties. The dose of the bottled waters is one to two half tumblers a day to begin with, and this should be gradually increased to two tumblers—never more—in the twenty-four hours. The same precautions are necessary during the use of these waters as are required in the administration of the pharmaceutical preparations of arsenic.

Before leaving Auvergne I shall say a few words about Clermont, which, though not usually resorted to as a watering-place, deserves some notice here. This town, which is also called Clermont Ferrand, is the capital of the department of the Puy-de-Dôme, and is situated seventy-eight miles west of Lyons and one mile and a half from Royat. It contains no less than fifteen mineral springs, which, according to the French nomenclature, belong to the class of chloro-bicarbonatées mixtes—that is to say, they contain a much larger proportion of lime and soda salts than the waters designated "chloro-bicarbonatées simples." It would, to my mind, be more intelligible to distinguish them by the affixes "strong" and "weak." These waters not only contain the bicarbonates of soda and of lime, but they also contain a fair proportion of the bicarbonate of iron, on which account they are found useful for anæmic, scrofulous, and rickety subjects; but from a deep-rooted prejudice they are seldom employed, and the medical men of the place have great difficulty in overcoming the objection which arises from the waters of some of the springs being utilised for the petrifaction of different objects for ornamental purposes, which are familiar to travellers, and which constitute a very important part of the industry of the place. I may, however, here observe that the term petrifaction is evidently a misnomer, as the objects in question are simply covered by a layer of calcareous matter, which is effected by allowing the water from certain of these springs to flow over them. It is more properly speaking a process of crystallisation, and the layers thus produced are as white and almost as hard as marble. In fact, the process is similar to what takes place in the manufacture of plaster-of-Paris splints. I have seen bunches of grapes, fish, &c., covered over in this way, and it struck me that the process may be of service in preserving fruit, and almost any other substance. By parity of reasoning, analogous effects are supposed by the vulgar to take place in those who drink the waters, in which case concretions would be formed in the intestines and in the bladder. Moreover, the town being within easy distance of Royat, the Clermontese prefer going to the latter, not only to drink its waters, but also to enjoy an agreeable walk.

Vichy is so well known that a description of the place would seem almost superfluous. It is certainly the most important and the most fashionable spa in France, the average number of visitors to it being about 40,000 a year. Vichy is situated on the right bank of the Allier in a large valley, surrounded by hills covered with a profusion of fruit trees and vineyards. It is 250 miles south-east of Paris, and its altitude is stated to be 880 feet; the air is temperate and pure. It is divided into the old and the new towns, Vichy-la-Ville and Vichy-les-Bains. The old town is picturesque, and it is evident from the Roman road and the ruins of olden times that Vichy was one of the foremost among the "aquæ calidæ" of the Romans. Vichy contains thirteen springs, which are used both for drinking and bathing. Eight of these belong to the State, and the other five are private property. A list of the springs with their composition will be found in a work by Dr. L. Grellety, entitled "Vichy-Cusset et leurs Eaux Minérales," and which is the most recent on the subject; but I may here give the principal: Source Chomel, Grande-Grille, Hôpital, which are thermal; Célestins, Hauterive, Lardy, Dubois, which are athermal. The waters of these springs are alkaline, the bicarbonate of soda and free carbonic acid forming the principal ingredients. They also contain small quantities of the bicarbonate of potash and magnesia with the arseniate of soda, all in varying proportions in the different springs. They are also divided, as has just been seen, into thermal and athermal, the temperature of the water ranging from 131° F. down to 59° F., the Source Chomel representing the former, and that of Dubois the latter. The hot or thermal waters spring naturally from the bowels of the earth, while the cold or athermal springs are produced by artificial boring. The

Digitized by Google

Grande-Grille is the most frequented, particularly by those coming from warm climates, as the waters of this spring are reputed to cure affections of the liver and spleen. Next in popularity is the Hôpital, and then comes the Célestine, the former for derangements of the digestive system, and the latter for those of the urinary organs. They are also specially recommended for gout, diabetes, and albuminuria. But although certain springs are reputed to be more suitable for some cases than others, yet Dr. Grellety, one of the physicians of the place, assured me that his personal experience had shown him that the choice of a spring is frequently a mere arbitrary measure, and the result of routine or fashion, for which the local physicians are somewhat to blame. Without wishing to deny that each spring has its own individuality, and possesses properties peculiar to itself, yet the chemical composition is so similar in them all, varying only in the temperature and in the proportion of the ingredients, that it struck me the distinctive lines of the therapeutic action of the different springs were too finely drawn, and that there was a great tendency to routine and refined systemisation. In this view I was fully borne out by Dr. Grellety, who said that a patient coming to a spa ought to place himself entirely in the hands of a local physician, as he alone can guide him in the choice of the water he is to make use of. The point particularly to be attended to was not so much the composition as the temperature of the water to be drunk; for while a patient could with a certain degree of impunity drink the water from a cold spring, he could not for any length of time tolerate that from a hot one.

Cusset is an old town a little more than two miles from Vichy, and from its proximity is considered a branch of the latter. It is resorted to as a promenade, or when the town of Vichy is overcrowded. The springs are athermal and highly mineralised.

Hauterive is looked upon as another branch of Vichy, though it is about four miles distant. Its waters are also athermal, and, like those of Cusset, may be preserved for a long time in bottles without undergoing any deterioration. The thermal springs, on the other hand, lose by travelling, not only in their chemico-physical composition, but in their therapeutic action. The local physicians are unanimous that for the waters of Vichy to be efficacious they must be drunk at the source itself. On the opposite bank of the Allier is to be seen a spring at Vesse, which goes by the designation of the "Source Intermittente," as the water spouts up only at certain intervals. The water is distinctly sulphurous, but I have never been able to ascertain why it is not utilised for medicinal purposes. It is preserved as a natural curiosity, and shown to visitors for twenty-five centimes each. The spouting takes place about once in the twenty-four hours; and by studying the time it takes for the water to be drawn in, the proprietors can, with the aid of other signs, predict within half an hour when the next spouting will take place, a notice of which is daily posted up at the casino and at the principal bathing establishment at Vichy. Vichy is almost yearly extending its boundaries, and it is expected will soon form one with the establishment at Cusset. It contains upwards of 400 bath-rooms, 56 douches, and 2 swimming baths. 3000 is the average daily number of bathers in the month of July; but, as at all the other health and pleasure resorts of France, the tourists and invalids this year have been almost exclusively natives, owing to the cholera scare. The season lasts from the middle of May to the end of September, and the average duration of the cure is three weeks. The treatment, being principally internal, may be carried out at any time of the year. It should on no account be abruptly stopped, but should be continued at intervals for some time after leaving the spa. The period most unfavourable for drinking the waters is during the greatest heat of the weather (July and August), as then the waters are not so well borne, diarrhœa and congestive phenomena being often induced. Like all the watering-places of France, Vichy claims to have been frequented since the time of the Gauls and Romans, who, besides being great warriors, seemed to attach greater importance to bathing than their descendants, if one may judge from the number of remains of bathing establishments which are to be seen to this day in various parts of the country. Paris itself possesses a very good specimen in the Palais des Thermes, at the Museum of the Hôtel de Cluny.

Paris, Sept. 23rd.

THE late Francis P. Hurd, of Wakefield, Mass., bequeathed $10,000 to the Massachusetts General Hospital.

NOTES FROM ABROAD.

THE first number of a new medical serial, *Boletin de Medicina*, appeared last July at Santiago, Chili.

Professor Pacini's manuscripts have been purchased from his heirs by the Italian Minister of Public Instruction.

The widow of Professor G. B. Ercolani has presented his veterinary library to the municipality of Bologna, his native city. For rare manuscripts and books in the special subject, the collection is said to be unrivalled in the world.

The germ theory of phthisis has attained to such a position in the estimation of foreign physicians, that Professor G. Sée has just published, through Delahaye and Lecrosnier, a volume entitled "De la Phthisie Bacillaire des Poumons."

The police authorities of Berlin have just issued an order requiring all medical practitioners to notify at once to the Sanitary Commission any cases of diphtheria under their care. The ravages from this disease are steadily on the increase in Paris, but compulsory notification is not permitted under the French law.

The official statistics of cholera in Italy bring up the number of cases to October 20th to 21,519, with 11,563 deaths. Genoa is now quite free from the scourge. The first case happened there on August 30th. From that day to October 20th the reported cases were 569, with 416 deaths, nearly 75 per cent. On September 29th no less than 40 of 65 cases proved fatal. At Dronero, in the province of Cuneo, 36 per 1000 inhabitants were attacked with cholera, and just half that number succumbed to it.

Antiseptic dressings, according to the *Progrès Médical*, have recently figured before the German tribunals. A servant having received a wound in the chest last April died from septicæmia under the care of Dr. N., who, despising antiseptic dressings, treated his patient according to ancient methods. The doctor, prosecuted under article 222 of the Penal Code, was condemned, the Correctional Tribunal holding "that every medical practitioner should keep himself informed on the accomplished progress of science, and have an exact knowledge of modern systems of treatment. If these had been employed, the life of Dr. N.'s patient might have been saved." Hence his legal liability for negligence. The judgment was sustained by the Court of Appeal.

THE WILL OF THE LATE SIR ERASMUS WILSON.

PROBATE of the will and codicil of the late Sir William James Erasmus Wilson, Kt., F.R.S., F.R.C.S., was granted on the 17th ult. to Messrs. Henry Palfrey Stephenson, Frederick Lane Linging, and Charles Alfred Swinburne, the executors, the gross value of the personalty being sworn to amount to over £264,000. The testator bequeaths three oil paintings—viz., a Sea Piece, by Salvator Rosa, "Three Sheep," by Sidney Cooper, and a Hurricane in the Bay of Biscay when the ship *Cleopatra* was cast away, by E. W. Cooke—to his wife Dame Charlotte Mary Wilson for life, and after her death to his trustees upon trust to present them to the South Kensington Museum or such other public institution in Great Britain as they may think most desirable in the interests of the public; £500 and all other his pictures, prints, books, plate, wine, furniture, and effects at his dwelling-house, 17, Henrietta-street, Cavendish-square, or any other dwelling-house he may have at the time of his decease, to his wife; an annuity of £500 to his brother George John Marris Wilson, M.D.; and £1000 to each of his executors. All his real and leasehold estates, and all his personal estate savouring of realty, he gives to his wife absolutely. The residue of his personal estate he leaves upon trust to pay the annual income to his wife for life, and at her death £5000 each, free of legacy duty, to the Royal National Hospital or Sea Bathing Infirmary for Scorfula only at Margate, the Royal Medical Benevolent College incorporated by Act of Parliament, the Medical Benevolent Fund, and the Society for the Relief of the Widows and Orphans of Medical Men. The whole of the ultimate residue of his pure personalty he bequeaths to the Royal College of Surgeons of England, the receipt of the President and Vice-Presidents for the time being, or any two of them, to be an effectual discharge for such residuary bequest to the

Digitized by Google

person or persons paying the same. No directions whatever are given as to how the Royal College of Surgeons are to apply these large funds, and the trustees of the will have no voice in the matter, as their duties will end with the paying over of the money.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

Diphtheria and Fever in and about Dartford, by Mr. J. SPEAR.—The neighbourhood of Dartford is acquiring an unfavourable sanitary history. The rural sanitary district was inspected in 1879 by Dr. Thorne Thorne on account of a prevalence of diphtheria; the urban and rural districts were again inspected by Mr. Spear in 1882 on account of diphtheria in the rural and enteric fever in the urban areas, and now again the whole registration subdistrict of Dartford is reinspected by Mr. Spear in 1884. The enteric fever prevalence in the urban district, previously reported on, was found to have ceased; but on the other hand diphtheria had become more general and fatal in the whole subdistrict, and the urban district, which had previously escaped this disease, was found to be implicated. So far as the sanitary circumstances of the urban district are concerned, the re-inspection resulted in ascertaining that a system of sewerage had been laid down, and that some commencement had been made in connecting houses with it, thus doing away with the ash-pits and privy-pits which had abounded there. So also there had been improvement in paving the streets and yards, and in enforcing the building bye-laws; but on the other hand, the extension of the Kent Company's water had been inadequate, and a large number of houses were still found to be dependent on supplies which are characterised as not only defective, but as often dangerous. The state of the rural district remains, in several important respects, most unsatisfactory. Diphtheria is maintained, recurring at intervals; and its reappearance is explained as affecting localities which have been previously invaded, and which still show many grave sanitary faults, such as lie within the power of a sanitary authority to remove. Such a statement, in an official report, throws a very serious responsibility on the authority, but the detailed descriptions which are given fully support the inference which is drawn. Botany Bay attracted attention in 1882 owing to the fatality from diphtheria and fever which it exhibited; during 1883 there occurred amongst its 300 inhabitants 3 deaths from diphtheria, 2 from so-called croup, and three from scarlet fever. In close proximity to the houses the ground is being riddled with cesspools. The original ones remain, and as fast as they fill fresh ones are dug; but they are so dug that the contents may to the utmost possible extent soak away. The soil also contains drains, some of which have been choked for six months, and in the midst of such filthy contrivances are sunk the wells which supply the inhabitants, notwithstanding the fact that the Kent supply is available. The sanitary condition of other localities which have already been previously reported on has also undergone no improvement. In Mr. Spear's last report he pointed out the generally defective character of the administration of the sanitary laws by the guardians, referring specially to their default in the abatement of ordinary nuisances. He also stated that the appointment of a single inspector of nuisances over an area of 35,000 acres and having a population of 20,000 was not calculated to ensure a proper performance of duty, especially as the officer in question was mainly engaged in other duties for the guardians. All remains just as it then did, and the only remedy seems to be for the inhabitants to make formal complaint to the Government under the Public Health Act.

Diphtheria in the Chippenham Rural District, by Dr. BLAXALL.—In this report Dr. Blaxall in the first case gives an account of some cases of diphtheria which were antecedent to those with which this outbreak was concerned. The particulars of the cases given are instructive, as showing how diphtheria may unwittingly be spread, and as indicating also that the infection is capable of being transmitted by persons who are not themselves affected. One other very important point transpires. Certain of the infected families occupied large farms supplying milk and cream to dairy companies, to whom the farmers have bound themselves under a heavy bond to report all cases of infectious disease occurring in or about their premises. But in these cases the actual character of the disease was not suspected, and hence no report could be made. The interests of the dairy customers could not therefore be protected, and the case affords another proof that in the boiling of all milk safety alone can be found. The epidemic more immediately considered took place at Lacock, where out of somewhat over 1100 people no less than 72 attacks and 8 deaths occurred, the outbreak dating from towards the end of November last. Thirty-eight of the cases were primary attacks in households, and of these 32 occurred in pupils of the Lacock school, who were in attendance there up to the dates of their respective attacks. Unwholesome conditions do not appear to have been specially concerned with the causation and spread of the disease, and the origin of the first case could not be precisely determined. But the affection once existing, personal communication between the sick and healthy was ample to account for the spread, and inquiry showed that after the school had been closed, its re-opening, on nearly every occasion, led to a fresh distribution of infection, some four or five children attending each time who were only just recovering from diphtheria. The village of Lacock needs numerous sanitary improvements as regards water-supply, means of closet accommodation, sewerage and drainage, &c. But of all indications to which such an epidemic as this gives prominence, the most urgent is the need for a wider provision of small hospitals, which would enable sanitary authorities at once to isolate first cases of infectious disease, and to keep them under supervision until they were really free from infection and fit to return to their homes and follow their usual avocations, whether these include school attendance or not. Such small hospitals in rural districts would save many lives, and would also prevent our system of compulsory education from acting as an indirect means of spreading disease.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Hull (Urban).—The borough of Hull had, in 1883, a birth-rate of 36·0 and a death-rate of 22·5 per 1000, on an estimated population of 176,296. The infant mortality was high. In the large towns of England the deaths under one year average 156 per 1000 births, but in Hull they reach 183. The great epidemic of scarlet fever from which Hull has suffered since 1881 has now practically subsided; the deaths from this cause during the year having fallen to 74. In dealing with the subject of infantile diarrhœa, Dr. Mason shows from the Hull records during the past fifteen years that the highest mortality occurs in the first or second week of August, the suddenness of the outburst being related to high temperature and low rainfall. In his opinion the origin and pathology of this disease point to a particular germ requiring a certain temperature for its development and propagation, and expending its virulence upon the intestines and lungs. He has not infrequently found amongst children that have died of diarrhœa a pneumonia secondary to the diarrhœa, and his investigations are now being directed in tracing the relationship between the two diseases. The prevalence of cholera in Egypt led to some action towards procuring a hospital for the purposes of the port, but the proceedings have unfortunately fallen through, both as regards the purchase of an old Admiralty vessel and as to acquiring a site on shore.

Taunton Urban District.—In so far as the death-rate is concerned Taunton has improved, although a rate of 21·5 per 1000 is by no means a small one for a borough of less than 17,000 people. The efforts to secure an improved water-supply have temporarily failed, owing to geological difficulties, but renewed efforts are being made in this direction. The system of sewerage remains defective, much more efficient means both of ventilation and of flushing being especially needed. Diphtheria, which has long hung about Taunton and its neighbourhood, was less last year, but the immediate isolation of first attacks and suspicious cases of sore-throat is still needed. Enteric fever was somewhat in excess in 1883, and it was largely dependent on the use of polluted well water, together with conditions favourable to the admission of sewer air into dwellings. The sanitary hospital received 72 patients, and the establishment is reported by Dr. Alford

Digitized by Google

as being more and more appreciated; persons able and willing to pay for their isolation making increasing use of it.

Taunton Rural District.—In the rural portion of the Taunton union the death-rate was 15·2 per 1000 living. Speaking generally, the means for the disposal of sewage is very unsatisfactory, and Dr. Alford warns the authority as to the consequences of leaving large cesspits and imperfect drains prevalent in the district. Diphtheria deaths still take a prominent place amongst the mortality records, and 28 cases of the disease were admitted into the sanitary hospital. The inspector of nuisances made a house-to-house inspection in thirty-eight parishes, and this exceptionally useful sort of work led to no less than 614 houses being dealt with as needing sanitary improvements.

Birmingham Urban District.—In his report for the third quarter of 1884 Dr. Alfred Hill shows that the epidemics of small-pox and scarlet fever, from which the borough had for some time suffered, have subsided. At the time he writes he says that not a single case of small-pox existed to his knowledge, whether in or out of the hospital; and as regards scarlet fever, though this disease never disappears from the borough, yet its epidemic prevalence had passed away. Diarrhœa caused a large fatality; in all, 559 deaths, or 70 per cent., of the gross number due to the seven principal infectious diseases occurred, the death-rate from this one cause amounting to 5·3 per 1000 of the population per annum. This fatality took place in connexion with an exceptionally hot August, the temperature during the month having been 3·6° above the average; indeed, the highest temperature ever registered by Dr. Hill in Birmingham occurred on the 11th of the month. There was also an exceptionally small rainfall; none fell for twenty-five days, and a reasonable average was only maintained by a fall of nearly one inch on the last day of the month.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

During the week ending the 1st inst., 6000 births and 3464 deaths were registered in twenty-eight of the largest English towns. The annual rate of mortality in these towns, which in the two preceding weeks had been 21·1 and 20·9 per 1000, further declined last week to 20·6. During the first five weeks of the current quarter the death-rate in these towns averaged 20·5 per 1000, against 21·0 and 19·7 in the corresponding periods of 1882 and 1883. The lowest rates last week in these towns were 15·0 in Norwich, 16·5 in Nottingham, 17·1 in Brighton, and 17·2 in Birkenhead. The rates in the other towns ranged upwards to 26·3 in Bolton, 26·9 in Blackburn, 27·9 in Cardiff, and 28·8 in Preston. The 379 deaths referred to the principal zymotic diseases in the twenty-eight towns included 84 from diarrhœa, 67 from "fever" (principally enteric), 66 from scarlet fever, 57 from measles, 50 from whooping-cough, 31 from diphtheria, and 24 from small-pox. No death from any of these diseases was recorded last week in Brighton; while they caused the highest death-rates in Cardiff, Hull, and Preston. The largest proportional mortality from "fever" occurred in Derby, Preston, and Halifax; from scarlet fever in Sunderland, Cardiff, and Sheffield; from measles in Sunderland, Cardiff, and Sheffield; and from whooping-cough in Halifax and Hull. The 31 deaths from diphtheria in the twenty-eight towns included 22 in London and 4 in Liverpool. Small-pox caused 21 deaths in London (exclusive of 16 London cases registered outside Registration London), 2 in Birkenhead, and 1 in Hull. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had been 504, 558, and 596 on the three preceding Saturdays, were 580 at the end of last week; the new cases admitted were 104, against 68, 144, and 173 in the three preceding weeks. The Highgate Small-pox Hospital contained 18 patients on Saturday last, 3 new cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which in the six previous weeks had increased from 159 to 274, further rose to 348 last week, but were 38 below the corrected weekly average. The causes of 68, or 2·0 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Brighton, Bristol, Nottingham, and in three other smaller towns. The largest proportions of uncertified deaths were recorded in Leicester, Salford, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 21·3 and 21·4 per 1000 in the two preceding weeks, rose to 22·5 in the week ending the 1st inst., and was 1·9 above the mean rate during the same period in the twenty-eight large English towns. In the Scotch towns the rates last week ranged from 16·0 and 16·8 in Paisley and Perth, to 21·5 in Greenock and 26·7 in Glasgow. The 543 deaths in the Scotch towns included 25 which were referred to scarlet fever, 23 to diarrhœal diseases, 22 to whooping-cough, 20 to diphtheria, 14 to measles, 12 to "fever" (typhus, enteric, and simple or undefined), and not one to small-pox; in all, 116 deaths resulted from the principal zymotic diseases, against 101 and 110 in the two previous weeks. These 116 deaths were equal to an annual rate of 4·8 per 1000, which was more than double the mean rate from the same diseases in the twenty-eight English towns—only 2·3. The 25 fatal cases of scarlet fever showed a further increase upon recent weekly numbers, and included 17 in Glasgow (against 14 and 13 in the two previous weeks), 5 in Greenock, and 2 in Edinburgh. The deaths referred to diarrhœal diseases, which had declined in the five preceding weeks from 52 to 21, were 23 last week, including 5 in Glasgow, 6 in Dundee, and 4 in Aberdeen. The deaths from whooping-cough, which had been 18 and 15 in the two previous weeks, rose to 22 last week; 7 occurred in Glasgow and 6 in Dundee. The 12 deaths referred to "fever," showing a decline of 3 from those in the previous week, included 8 in Glasgow and 3 in Edinburgh. Of the 14 fatal cases of measles, considerably fewer than any recent weekly number, 8 occurred in Glasgow and 6 in Aberdeen. The 112 deaths referred to acute diseases of the respiratory organs in the eight Scotch towns showed an increase of 27 upon the low number in the previous week, but were 10 below the number returned in the corresponding week of last year. The causes of 76, or 14 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 30·2 and 26·8 per 1000 in the two preceding weeks, further declined to 24·7 during the week ending the 1st inst. During the first five weeks of the current quarter the death-rate in the city averaged, however, 27·4 per 1000, the rate for the same period not exceeding 18·6 in London and 17·9 in Edinburgh. The 166 deaths in Dublin last week showed a further decline of 14 from the numbers in the two previous weeks, and included 25 which resulted from the principal zymotic diseases, against 25 and 29 in the two preceding weeks; of these, 10 were referred to scarlet fever, 9 to "fever" (typhus, enteric, or simple), 4 to diarrhœa, 2 to whooping-cough, and not one either to small-pox, measles, or diphtheria. These 25 deaths were equal to an annual rate of 3·7 per 1000, the rate from the same diseases being 2·1 in London and 2·3 in Edinburgh. The fatal cases of scarlet fever, which had been 5 and 12 in the two previous weeks, declined again to 10 last week, and the fatal cases both of diarrhœa and of whooping-cough were less numerous than in the previous week. The deaths referred to "fever," however, which had been 10 and 6 in the two previous weeks, rose again to 9 last week. Six inquest cases and 5 deaths from violence were registered during the week, and 69 of the 166 deaths occurred in public institutions. The deaths both of infants and of elderly persons showed a further decline from recent weekly numbers. The causes of 21, or nearly 13 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.—Surgeon-Major Allan Nesbit Fox, M.B., is granted retired pay, with the honorary rank of Brigade Surgeon.

Sudden orders, it is announced, have been received by the general commanding the Aldershot district to arrange to despatch about 100 men of the Medical Staff Corps to embark at once for conveyance to Egypt. Orders were also received to prepare a strong detachment of the same corps for immediate embarkation for South Africa.

ADMIRALTY.—The following appointments have been made:—Surgeons Edw. W. von Tunzelmann and Edw. B.

Digitized by Google

Townsend, to the *Duke of Wellington*, additional, for Haslar Hospital, reappointed; Surgeon James M. Rogers, to the *Royal Adelaide*, additional, for Plymouth Hospital; Surgeon C. L. Nolan, M.B., to the *Indus*; Surgeon Francis H. Julyan, to the *Pembroke*, for disposal; Surgeon Edward C. Ward, M.D. to the *Repulse*; Surgeons Herbert W. G. Doyne and Thomas Dunlop, M.B., to the *Royal Adelaide*, for disposal; Surgeon Alexander B. Murdock, M.B., to the *Duke of Wellington*, for disposal; Surgeon Samuel Johnson, M.B., to the *Asia*, for disposal; Surgeon H. R. Osborne, to the *Valiant*; Surgeon Alexander G. Wildey, to the *Duke of Wellington*; Harold F. D. Stephen, M.B., to the *Cambridge*; Surgeon Patrick B. Handyside, M.B., to the *Asia*; Surgeon William R. M. Colthurst, M.D., to the *Flora*; Surgeon Percy W. Bassett-Smith, to the *Rambler*.

Correspondence.

"Audi alteram partem."

THE CHOLERA BACILLUS.

To the Editor of THE LANCET.

SIR,—You will, I am sure, excuse my troubling you with another brief communication relative to the cholera bacillus.

You state in your issue of Oct. 18th that Dr. Aurelio Bianchi of Florence has just collected and published some manuscript observations made by his late teacher during the cholera epidemic which prevailed in Florence in 1856, and that "the editor claims that Pacini was the first who instituted microscopic researches with a view to discover the nature of the Asiatic plague, and that he described, with much precision and truth, under the generic name of 'vibrio,' the organisms now known as 'microbes.'" The claim thus set forth cannot be sustained, and is capable of disproof on evidence not to be set aside.

Professor Pacini's observations were made on cases which occurred during the cholera epidemic of 1855, and the first microscopical examination was made on the body of a man who died on February 12th of that year. My investigations were made during the epidemic of 1854, and my three reports—(1) On the Microscopical Examination of different Waters, principally those used in the Metropolis during the Cholera Epidemic of 1854; (2) On the Microscopical Examination of the Blood, and Rice-water and other Excretions of Cholera Patients; (3) Reports stating the Results of the Microscopical Examination of the Skin and Clothes of Cholera Patients—were published in the "Appendix to the Report of the Committee for Scientific Inquiries in relation to the cholera epidemic of 1854, a committee appointed by the Government of that time. The report first named was dated December 21st, 1854; the second report, which contained the description of the results of the microscopical examination of the blood, rice-water evacuations, and other excretions of cholera, bore date January 22nd, 1855; while the third report bore, I believe, the same date. These dates are therefore conclusive.

Stated in the fewest possible words, I showed in these several reports that in the impure waters taken from the river Thames, with which London was then supplied, "vibriones," which would now be called "microbes" and "bacilli," were of frequent occurrence in very notable quantities; that the blood of persons affected with cholera was entirely free from such organisms, as also was the urine, but that the rice-water evacuations of cholera abounded during the life of the patient with myriads of vibriones, some of which, from the description recently given by Koch of his cholera bacillus, were undoubtedly identical with what he has described under that name.

Lastly, that the textures of the skin itself were entirely free from any organisms, but that the clothes worn by cholera patients, by having become stained with the evacuations abounded with vibriones identical with those present in the evacuations.

I am, Sir, your obedient servant,

ARTHUR HILL HASSALL, M.D. Lond.

San Remo, October 26th, 1884.

ENGLISH MEDICAL DEGREES FOR ENGLISH STUDENTS.

To the Editor of THE LANCET.

SIR,—Your able leader of last Saturday on the disastrous effects of the competition of the Scotch universities on London schools will surprise no one. And your account of the hardship to English students wanting medical degrees will be received with gratitude. As a Scotch graduate I cannot, indeed, admit the justice of your contention that Scotch degrees are as easy of attainment as the diploma or licence of English colleges. Such a statement is refuted by the experience of those who have passed both examinations and by the position taken ultimately in the profession by the graduates of the Scottish universities, as well as by reference to the curriculum of the respective bodies. I must admit, however, with grief, that the Scotch universities have chiefly themselves to blame for the persistency with which such disparagement of their examinations is expressed by yourself and by other English authorities. Their recent junction with the Scotch Corporations for the purpose of obstructing or defeating medical legislation justifies the conclusion that they are afraid of an independent board where their work would be tested at the least possible cost to their graduates and with the greatest advantage to their reputation and to the State. I readily admit that graduation on such a scale as that going on in Scotland now may readily become a temptation, and, as a Scotch graduate, I wish to see the Universities of Scotland accept, and even invite, any independent test that a reasonable and friendly Government may suggest. But if they persist in refusing such a test, it will certainly be the duty as well as the wisdom of English teachers, especially those of London, to take some trouble to create a university in London in which medical graduation can be obtained on some such terms as those of Scotland. It would be simply disastrous if the enormous clinical field of London and its unsurpassed staff of capable teachers were to cease to be in demand for the purposes of English medical education. And there is no excuse for the impracticable regulations of the London University, of which no material section even of its own medical graduates, I believe, approves. They are a crying injustice to diligent and capable English students, who may fairly claim to have an English degree within reach.

On one other point, however, Sir, I must beg seriously to differ from you—viz., in your opinion that a "University of Physicians and Surgeons" will suffice to meet this great want. "A University of Physicians and Surgeons!" This is an expression which does not sound well. There is a "shoppy" ring about it. A university, as Dr. Johnson says, is "a school where all the arts and faculties are taught and studied." Only from such a university can degrees proceed, and it is certain that degrees from a "University of mere Physicians and Surgeons" would never be able to compete with universities in the ancient and wider sense. Is it really past hoping for that the University of London will reconsider its duties on the pretext that it would practically disestablish the ancient colleges by co-operating with them? Rather by entering into co-operation with them, in my judgment, would it give these ancient colleges a new status without necessarily disturbing their existing functions. Be this as it may, there ought to be no insuperable difficulty in founding a university in London that will do for English students of medicine what the Scotch universities do for Scotch practitioners, and for so large a proportion of English students, but in doing which they refuse to satisfy English opinion.

I am, Sir, your obedient servant,

Nov. 6th, 1884. A SCOTCH GRADUATE.

THE LATE DR. SAMUEL RABBETH.

To the Editor of THE LANCET.

SIR,—A meeting was held this afternoon at King's College, at which many eminent members of the medical profession and other distinguished persons were present, in honour of the late Dr. Samuel Rabbeth, and I am desired, as one of the secretaries, to ask your assistance in making its purpose known to the profession. A large committee was appointed, including among others the chairman and vice-

Digitized by Google

chairman of King's College and the Royal Free Hospitals, Sir William Bowman, Sir William Gull, Sir Joseph Lister, Dr. Priestley, Professors Johnson and Wood, the Rev. Dr. Stokoe, and Mr. F. J. Gant. His Grace the Archbishop of Canterbury has kindly consented to be honorary president. This committee will take into consideration the best means of commemorating the name and sacrifice of Dr. Rabbeth, at the two hospitals with which he was connected and at the University of London, of which he was a distinguished graduate. The Principal of King's College and R. Ruthven Pym, Esq., have been requested to act as treasurers. Messrs. Coutts and Co., Strand, have kindly consented to receive subscriptions to the fund.

I am, Sir, yours truly,

JOHN CURNOW, M.D.,

King's College, Nov. 5th, 1884. Dean of the Medical Faculty.

P.S.—Sir Wm. Jenner has just written me a letter expressing his sympathy with the movement, desiring that his name may be added to the committee.

SMALL-POX AND BLINDNESS.

To the Editor of THE LANCET.

SIR,—The necessity for and the great value of vaccination and revaccination have been recently brought before us in a very prominent way by the medical press. The facts which I am about to state (which are somewhat akin to those contained in Mr. Tweedy's interesting letter) are of a class not usually mentioned when dealing with this subject and are most convincing proofs of the efficacy of vaccination. The committee appointed by the Ophthalmological Society to report upon the Government scheme for the prevention of blindness from ophthalmia neonatorum, which I had proposed and which was subsequently adopted by the Society, having thought it advisable, inquiries were made to ascertain what percentage of the inmates of the institutions for the blind was due to purulent ophthalmia. With that object I examined the records of the Deaf, Dumb, and Blind Institution at Belfast, and, being strongly impressed by what was there disclosed regarding small-pox, I made the following notes:—Small-pox was the cause of the blindness of 26 of the first 87 recorded blind pupils admitted from 1845 till Oct. 18th, 1859; of two of the next 31 admitted; and of not one of the remaining 98 (up till the present year). I may present the matter in a much more striking light, thus:—Of the first 98 admissions, small-pox caused 27; whilst of the last 98 admissions it did not cause a single one. This certainly does not require comment.

I am, Sir, your obedient servant,

DAVID MCKEOWN, M.D.

St. John-street, Manchester, Oct. 1884.

To the Editor of THE LANCET.

SIR,—In your issue of the 18th inst., Mr. Tweedy narrates a striking instance of loss of sight caused by small-pox after wilful neglect of vaccination. I can supply a similar case. I lately saw at St. Mary's Hospital a young woman who had lost her right eye from variola, and whose face was very deeply pitted and disfigured. I found that she had no vaccination scars. On inquiry, she informed me that her father, having lost a baby soon after vaccination, had refused to allow his three youngest children to be vaccinated. Some years ago the eldest of these three died rapidly of "black fever," and very soon afterwards the youngest (my patient) had a severe attack of small-pox, and lost her eye. The second of the three insisted on being vaccinated, and she entirely escaped the disease. Comment is surely needless.—I am, Sir, yours truly,

DAVID B. LEES, M.D., F.R.C.P.

Thurloe Houses, S.W., October 28th, 1884.

THE LATE PROFESSOR COHNHEIM.

To the Editor of THE LANCET.

SIR,—A committee has been formed in Germany from amongst the friends and pupils of the late Professor Cohnheim, whose premature death a few months ago has been most deeply and widely lamented throughout the medical world, for the purpose of erecting a suitable monument over his grave. To the profession generally Cohnheim was only known for his great scientific attainments, and uncommon originality of research; but to a large circle of friends and pupils, who came to study under him from all parts of the world, he had greatly endeared himself by the charm of his manners and the large and warm-hearted sympathy which he freely gave to all those who were, like him, striving to cultivate the fascinating field of experimental pathology.

I have been requested by Professor Wagner of Leipzig, on the part of the committee, to acquaint, through the medium of your columns, Cohnheim's friends and old pupils in England and the United States with the object of the committee; and I shall be happy to receive and transmit any contributions towards the fund which is now being raised to the treasurer, Professor His of Leipzig. The list will be closed at the end of the year, after which a statement will be forwarded to all subscribers. I am, Sir, your obedient servant,

JULIUS ALTHAUS, M.D.

48, Harley-street, Cavendish-square, W., Nov. 4th, 1884.

PERILS OF CHLOROFORM ADMINISTRATION IN DENTAL OPERATIONS.

To the Editor of THE LANCET.

SIR,—When a student at St. Bartholomew's Hospital I remember Dr. Brunton saying that if a patient were not thoroughly under the influence of chloroform any irritation of the fifth nerve would produce slowing of the heart's action, and finally stoppage through the pneumogastric nerve. He clearly showed us this by an experiment on a rabbit. Surely this may account for the untimely and lamentable death of Mr. Macdonald, a brother medical man, at Nottingham, and many others, from operations on the face and teeth. I have always acted on Dr. Brunton's view, and, if giving chloroform for an operation implicating the fifth pair of nerves, have pushed it until the patient is completely under its influence. I think this is a matter which, if more generally known, might save human lives.

Yours faithfully,

W. E. BUCK,

Leicester, Nov. 4th, 1884. Physician to the Leicester Infirmary.

LIVERPOOL.

(From our own Correspondent.)

HOSPITAL SATURDAY AND SUNDAY.

THE annual meeting in connexion with Hospital Sunday was held on the 3rd inst. in the Town Hall, the Mayor presiding. The Committee reported that the collections for 1884 amounted (together with the contributions on Hospital Saturday) to the sum of £10,076. Although the number of collections showed an increase of twenty-one, the sum realised was £349 less than in 1883. There was also a decline of £11 in the Hospital Saturday boxes, and the total sum realised showed a decrease of £376. The total sum divided amongst the medical charities was £9800, and the expenses amounted to a trifle over 2½ per cent. on the total amount raised. The falling off in the receipts is much less than might have been expected considering the great and long continued depression in trade and commerce, but notwithstanding this a very general feeling prevailed at the meeting that the sum of £2524 raised by the working classes on Hospital Saturday ought to be at least doubled.

THE SCHOOL OF MEDICINE.

The number of students attending the anatomical classes shows a slight increase over that of last year. There is an ample supply of subjects, and the arrangements are so excellent that the mildness of the weather is not so unfavourable to dissection as it might have been. All the lectures are fairly well attended, and clinical lectures are given in rotation by the physicians and surgeons of the Royal Infirmary, and by the surgeons of the Lock Hospital.

MEDICAL CITY COUNCILLORS.

Mr. Robert Hamilton, Senior Surgeon to the Royal Southern Hospital, was re-elected one of the members for North Toxteth Ward by a very large majority. Dr. Cross, Mr. A. M. Bligh, and Mr. N. Marsh, surgeon, are also members of the City Council.

DEATH FROM CARBOLIC ACID POISONING.

Another has been added to the already frightfully large number of deaths from accidental poisoning by carbolic acid. On Sunday last a corporation scavenger was offered by a companion a bottle supposed to contain rum, but which unfortunately contained carbolic acid. Before the error had been detected he had swallowed the poison, and died soon afterwards. At the inquest an open verdict was returned.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

NEWCASTLE HOSPITAL SUNDAY.

MR. R. H. HOLMES, the hon. secretary, and one of the pioneers of the Hospital Sunday movement in the North, writes to our papers pointing out the very encouraging fact that notwithstanding the depression in trade the first published list of the late collection shows little or no falling off in amount as regards workshops, and when compared with the corresponding collection of last year. He further points out that a collection of one penny per week at the shops would yield a more satisfactory result at the end of the year than a single collection, while a penny a week would be scarcely felt by men in regular employment.

CHEAP FOOD AND CHEAP COOKING.

Mr. Walter Scott, of Paternoster-square and Newcastle, has brought out in a penny pamphlet form, well illustrated by coloured diagrams and tables, the lecture of the Rev. Moore Ede, rector of Gateshead, on the subject of penny dinners for school children. The publication appears at a time when much attention is being given to food economics. Mr. Ede acknowledges having received his inspiration on the subject from reading the article in the *Pall Mall Gazette* of April 3rd, 1884, entitled "My Social Revolution by the ex-Brandy King of Sweden," which was an account of some social movements inaugurated by Mr. L. O. Smith of Stockholm, who was at one time head of the brandy trade in Sweden. He also acknowledges the assistance he received in his work by valuable receipts from Mr. and Mrs. Burgess, of the now celebrated Rounden School; nevertheless, the Rev. Mr. Ede must be regarded as the pioneer of the cheap dinner movement in our Northern counties, and he has spared neither trouble nor expense in its development. I saw at Messrs. Walker and Emley's factory, Newcastle, the other day, a penny dinner cooker in process of manufacture; it is circular in form, and very portable and light; the diameter varies according to the required capacity; the outer case is made of galvanised, and the inner one of tinned, sheet-iron, the space between the two being filled by a special non-conducting material. By means of this nearly all the heat from the patent gas-burners, which are fixed below, is utilised; a small expenditure of gas is sufficient to boil the water and cook the food efficiently. Soups and some other foods are cooked in a loose inner pan, which almost fills the internal space of the cooker, leaving only a margin for the surrounding boiling water. As the Rev. Mr. Ede points out, the adoption of suitable apparatus for cooking is essential to the success of the system, and he believes that Messrs. Walker and Emley have solved the problem by the introduction of their penny dinner cooker.

At Gateshead Drs. Mearns and Purdie have received testimonials from the ambulance classes which have been under their instruction.

Sir Wm. Armstrong has, with his usual munificence, sent a donation of £500 towards the building fund of the Newcastle Eye Infirmary. The late bazaar at Darlington of the hospital and dispensary has yielded the handsome amount of £2600.

Newcastle-on-Tyne, Nov. 3rd.

DR. LOUIS ALEXANDER DUGAS has recently died at his home in Augusta, Ga., in the seventy-eighth year of his age. Dr. Dugas served several times as President of the Medical Association of Georgia, and from 1851 to 1858 he acted as editor of the *Southern Medical and Surgical Journal*.

GLASGOW.

(From our own Correspondent.)

THE ROYAL INFIRMARY.

MUCH dissatisfaction has existed for some time among the students at the Royal Infirmary School on account of the fact that so few of the appointments on the resident staff have fallen to their share, Glasgow University students and graduates from Edinburgh being accepted to the almost entire exclusion of those educated at the Royal Infirmary itself. This shows bad policy on the part of the infirmary directors, and will tend much to render the school unpopular; it conveys, moreover, an unjust reflection on their own students, who have reason for expecting to be fairly represented on the staff.

CHANCELLORSHIP OF THE UNIVERSITY.

It seems now certain that this office will fall to the Earl of Stair, as his only opponent, the Marquis of Bute, has withdrawn from the threatened contest. The Marquis, in connexion with his withdrawal, has addressed to the Principal of the University a letter marked throughout by singular grace and elevation of tone.

MEDICAL BURSARIES.

Mrs. Monteath, Greenbank, Dowan-hill-gardens, Glasgow, has placed in trust the sum of £1000 for the establishment of two bursaries to be awarded to students of Glasgow University who gain the highest number of marks in the subjects of anatomy and physiology at the professional examinations on these subjects held during the year. A bursary of the value of about £20 will be awarded annually in November, and will be tenable for two years. Mrs. Monteath has founded these bursaries in memory of her husband, the late Mr. John Monteath, and she directs that it be represented to the holders that they should feel themselves in honour bound after graduation to render professional assistance to the poor as much as may lie in their power.

PANIC ACCIDENT IN A MUSIC HALL.

Another of these shocking accidents has occurred in Glasgow, happily on a smaller scale than in Sunderland last year. An audience of about 1300 rushed in a panic from a music hall in which a false alarm of fire had been raised. Fourteen persons were killed outright, and over twenty injured. The injuries, with the exception of two fractures (one of the arm and the other of the clavicle) consisted mainly of severe nervous shock.

RECTORIAL ELECTION, ABERDEEN UNIVERSITY.

Dr. Bain is put up by the Liberals for re-election to this important office. He is recommended on educational grounds solely and on no political grounds whatever. His opponent is Lord Randolph Churchill, who has accepted nomination.

PARIS.

(From our own Correspondent.)

THE CHOLERA.

SINCE my report of last week there have been nine fresh cases of cholera at Ypost, and three deaths. The disease has broken out at Nantes, and from the 24th of October to the 4th of November 72 cases occurred, but the number of deaths have not been reported. The affected provinces are becoming less in number. The following are the districts where cholera is now prevailing: Bouches-du-Rhône, Gard, Pyrénées-Orientales, Var, Oran, Seine Inférieure. The total number of deaths from the disease were 31 from the 11th to the 17th of October, and 19 for the week ending the 24th of October. In Algiers the mortality from 11th to the 17th October was 52, from the 18th to the 24th October it was seven. No reports are now published from Toulon and Marseilles, as these places have been for some time free from cholera.

ILLNESS OF M. FAUVEL.

At the meeting of the Academy of Medicine yesterday the President announced that M. Fauvel, the eminent epidemiologist, and Vice-President of the Academy, is dangerously ill, being laid up with double pneumonia.

Paris, Nov. 5th, 1884.

MEDICAL NOTES IN PARLIAMENT.

Thames Valley Drainage.

ON Monday, in the House of Commons, in reply to a question by Mr. Giles, Mr. C. Russell stated that the Local Government Board have been in communication with the several local authorities with a view of determining whether the pending inquiry into the Thames Valley drainage shall be limited to the dissolution of the Lower Thames Valley main sewerage, or the question of the separation from the district of certain constituent authorities. The constituent authorities who have expressed themselves as desirous of being separated from the joint district are the urban sanitary authorities of Kingston, Richmond, Heston and Isleworth, New Malden, and East Moulsey, and the rural sanitary authority of the Kingston Union.

Chlorine Poisoning at Runcorn.

On Tuesday, in reply to Mr. Warburton, Mr. G. Russell stated that no information as to the alleged deaths of two children from suffocation by chlorine gas from alkali works at Runcorn had as yet been received, but that inquiry would be made on the subject.

Indian Medical Service.

On Thursday, Mr. J. K. Cross, in answer to Mr. Gibson, who inquired whether any, and if so what, steps had been taken by the Indian Government to lessen or remove the grievances of the Indian Medical Service, said the measures taken for reducing the number of unemployed medical officers in India had been efficacious. The Government of India had telegraphed that there are now only two unemployed officers in Bengal, and they have promised to communicate the number still unemployed in Madras and Bombay. It has been decided to place all surgeons of the Indian Service not holding executive charge on precisely the same footing in respect to pay as surgeons of the Army or British Medical Department similarly situated. The lower rate of pay hitherto called "unemployed pay" will for the future be called grade pay, and will only be given when the officer is in receipt of staff salary in addition to his pay.

Over-pressure in Board Schools.

Mr. Stanley Leighton inquired of the Vice-President of the Committee of Council whether, in view of the statements contained in a report made at his request, by Dr. Crichton Browne, he would take steps to procure the appointment of a commission of medical men unconnected officially with the Education Department to inquire whether the present method of applying the Elementary Education Act injuriously affected the health of the children and teachers.—Mr. Mundella replied that, as an efficient and impartial inquiry had already been undertaken, he did not see the necessity for a second inquiry. The most careful precautions had been taken to guard against over-pressure, and the operation of the revised regulations under the new code were being carefully watched. The public discussion of this question had resulted in the establishment in the metropolis of voluntary associations with the object of supplying food and clothing to necessitous children attending schools, and that with the co-operation of three or four members of the House he had been able to offer considerable help to those committees.

Examination of Surgeons-Major.

Sir Henry Fletcher inquired of the Secretary of State for War, with reference to the regulations in regard to the examination of surgeons-major for promotion to the rank of brigade surgeon, as laid down in the Army Circular, dated Nov. 1st, 1884, whether there was any precedent for examining officers ranking as lieutenant-colonel of six years' standing, and was it proposed to extend these examinations to the other scientific branches of the army; was it a fact that several of the senior surgeons-major are over fifty years of age; and was it the case that H.R.H. the Field Marshal Commanding-in-Chief, when giving evidence before Lord Morley's Committee, expressed an opinion against subjecting such old officers to examination; and by whose recommendation were these examinations instituted.—The Marquis of Hartington, in reply, stated there were several surgeons-major over fifty years of age who before being promoted to the rank of brigade surgeon would be required to undergo examination. It was the case that H.R.H. the Field-Marshal Commanding-in-Chief, in his evidence before Lord Morley's Committee, expressed an opinion adverse to the examination of officers so advanced in life; but after full consideration of the difficulty of selecting officers for the rank of brigade surgeon, the examination was determined upon at the suggestion of the Director-General. There was probably no precedent for the examination of similar rank and service; but there was probably no case in which the grounds of selection for promotion were so difficult to arrive at. There was no intention to propose an extension of the system of examination to the corresponding combatant ranks.

Obituary.

GEORGE LUMGAIR, M.D., F.R.C.S.E.

ON the 1st inst. the death occurred of Dr. George Lumgair, one of the best known and most highly respected practitioners in Fife. Born at Arbroath, Dr. Lumgair received his medical education at the University and College of Surgeons, Edinburgh, and in 1837 commenced the active practice of his profession at Largo, Fifeshire, where he continued at work for forty-seven years. Although greatly troubled by bronchial asthma, he worked perseveringly, and is only known during this long period to have taken three holidays. Two years ago he was appointed Justice of the Peace, and he was unanimously elected first President of the Fifeshire Medical Association when that body was constituted two years ago. At the time of his death Dr. Lumgair was in the sixty-seventh year of his age.

T. F. WATTS, M.B., C.M.

WE have to record the death, at the early age of thirty-two, of Thomas Fowle Watts, M.B., C.M., Medical Officer H.M. Convict Prison, Dartmoor, which occurred after a short illness on October 23rd. Mr. Watts was appointed assistant surgeon at the above prison, November 26th, 1880. On July 27th, 1881, he left Dartmoor for Liverpool, and on August 25th, 1882, returned as medical officer to Dartmoor. The funeral took place on October 28th, and the respect in which the deceased gentleman was held was shown by the presence, in addition to that of his own immediate relatives, of all the principal prison authorities and warders, and also of the greater part of the villagers and of many friends who had come from a distance.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentlemen were admitted Members of the College on Oct. 30th:—

Cullimore, Daniel Henry, M.D. Brussels, Welbeck-street.
Daly, Edward Owen, M.B. Oxford, Hull.
Maudsley, Henry, M.D. Lond., University Hospital.
Oliver, James, M.B. Edinburgh, Montague-street.
Wilkinson, William Camac, M.B. Lond., Manchester-street.

On the same day the following gentlemen were admitted Licentiates of the College:—

Anderson, Daniel Elie, Endsleigh-gardens.
Baillie, Robert Alexander, Radnor House, Blackheath-park.
Bidwell, Herbert, St. Thomas's Hospital.
Blight, William Lyne, Pendavey, Sladesbridge.
Bond, Charles Knox, Lupus-street.
Byrne, George, Withington, Manchester.
Cann, Ralph Thomas, Lambeth-palace-road.
Chapman, Harry Cecil, St. Mary's-terrace.
Crocker, John Hedley, Lyncham Lodge, Lee-road.
Davies, Jenkin, Larkhall-lane.
Des Vœux, Harold Antoine, St. George's Hospital.
D'Monte, Dominick Anaclete, Melville-terrace, Edinburgh.
Ellis, Charles Cartwright, Clarendon-road.
Fox, Herbert, Brambletye, Park-hill, Croydon.
Gray, Thomas Underwood, Essex-road.
Griffiths, Charles Thomas, Cathcart-road.
Habgood, Henry, Chewton Mendip, Bath.
Hall, Alfred Richard, Straarear-place.
Harlock, Harry, Buckfastleigh.
Hughes, Edgar Alfred, Onslow-gardens.
Humphreys, Charles Style, Chichester-street.
Jones, Isaiah Henry, Maida-vale.
Kerby, Robert John, Warltersville-road, Crouch-hill.
Koettlitz, Maurice, Bootle, Liverpool.

Digitized by Google

Laslett, Thomas George, Grosvenor-terrace, Liverpool.
Livermore, William Leppingwell, Queen's-road, Finsbury-park.
Low, Charles William, Vicarage-park, Plumstead.
Marten, Robert Humphrey, Granby-street.
Miles, George Edward, Northumberland House, Finsbury-park.
Morgan, George, Market Drayton.
Santi, Philip Robert William, Doughty-street.
Stevens, Percy Richard, Oakley-square.
Thomas, Benjamin Wilfred, Heathcote-street.
Voisin, Alexander Bishop, St. Heller's, Jersey.
Weakley, Alfred James, Ramsay-road, Leytonstone.

The following gentlemen passed the Primary Examination for the licence of the College on the 4th inst:—

G. W. Adams, O. W. Andrews, E. C. Arnold, J. Bamfylde, G. R. S. Banbury, J. B. H. Booth, R. F. Bowie, H. W. Branson, A. A. Brockat, F. A. Brooks, R. P. Brooks, C. H. Buckley, K. T. Buée, J. T. Calvert, D. M. L. Campbell, P. T. Carpenter, J. S. Caskey, C. W. M. Castle, F. E. Cave, R. H. Chapman, A. D. Chapple, G. L. Cheatle, J. W. Cockerill, F. G. Connolly, F. Corner, J. H. Cox, W. C. Croxford, A. E. Deane, S. B. C. De Butts, A. L. Devenish-Meares, F. J. Dewes, W. F. Dewsnap, C. J. Deyns, H. M. Doyle, C. A. Ducket, E. H. Ellison, E. W. Emtage, F. G. Failes, J. H. Fardon, F. J. Fletcher, T. W. Francis, H. S. Fremlin, C. Fryer, F. E Gibbens, J. W. Gill, H. E. Gough, C. Greene, R. P. Griffin, W. G. Gyton, C. D. Hamilton, F. A. Harger, G. J. Harris, R. Hedley, Habeeb Jabboor, Hanna Jabboor, C. L. S. James, W. C. Jarvis, J. G. Johnson, E. E. King, F. J. Knowles, R. Lake, A. P. Lange, G. S. Leggatt, R. Leigh, P. G. Lewis, C. W. Lockyer, W. W. L. McLean, W. Marris, F. G. C. Martin, J. P. Martin, R. Martyn, S. C. H. Moberly, F. P. Moles, J. C. Morgan, E. Nason, P. L. Nettleship, E. J. Nixon, F. J. Oxley, E. B. Parfitt, R. H. Penton, J. Pietersen, C. F. Pridham, H. Rhodes, N. B. Robinson, J. P. Roughton, A. B. Roxburgh, D. N. Ruck, W. J. Rugg, H. A. Sansom, T. F. Shackleton, J. S. Sharman, C. W. Smeeton, L. M. Snow, P. B. T. Stubbs, A. M. Sully, W. R. Thomas, G. Thorpe, H. B. Trist, J. F. Vincent, S. G. Vinter, L. Vintras, J. P. Wagstaff, C. G. Wallis, J. J. Weaver, J. Wigg, T. H. Williams, C. J. Wills, H. E. Winter, C. F. Wright.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Oct. 30th:—

Parker, W. Turnour, Lillie-road, Fulham.
Sansom, Charles Lane, Devonshire House, Anerley.
Sugden, Edgar Brewitt, Adamson-road.

ON the 4th inst., medallions were presented by Lady Brassey to certificated pupils of the Woolwich Centre of the St. John Ambulance Association.

A MEDICAL CENTENARIAN.—The "New York Medical Journal" says that Dr. C. C. Graham, of Louisville, completed the age of one hundred years on the 10th inst.

ROYAL INSTITUTION OF GREAT BRITAIN.—William Miller Ord, M.D., has been elected a manager, in the room of the late Right Hon. Lord Claud Hamilton.

THE Swansea Choral Society's bazaar has resulted in an addition to the funds of the Swansea Hospital of £500.

THE Ocean Steam Yachting Company propose to despatch their Steam Yacht *Ceylon* for a cruise of sixty-five days to the West Indies, in December next, provided that a limited number of passengers are secured.

UNIVERSITY OF CAMBRIDGE.—The third examination for the degree of Bachelor of Medicine, part 2, will begin on Wednesday, December 10th. Mr. Walter Heape has been appointed Demonstrator in Animal Morphology.

AN evening fête is to be held on Wednesday, the 26th inst., at the Bread Reform Exhibition, Humphrey's Hall, Knightsbridge, to establish a fund to provide penny breakfasts and dinners to poor London school children.

SUPERANNUATION.—Mr. Robert Jones, M.R.C.S., L.S.A.L., late Medical Officer of the Conway District and Workhouse of the Conway Union, has been awarded a superannuation allowance of £40 a year.

IN view of the difficulty of enforcing the Vaccination Acts in Leicester, the board of guardians have decided to lay the whole circumstances before the Local Government Board and to solicit their advice.

BEQUESTS.—By the will of the late Dr. Alex. Gibb, late Inspector General of Hospitals, who died at Edinburgh on the 21st ult., the following bequests are left:—£100 to the Edinburgh Infirmary; and the balance, after the payment of certain other legacies, to be equally divided among the Royal Infirmary (for the Building Fund), the Convalescent Hospital, the General Dispensary, the Hospital for Incurables, and Sheriff Watson's Industrial School, all in Aberdeen. The share of each institution participating in the residue, after payment of all the legacy duties, &c., will amount to upwards of £200.

ALCOHOL IN RELATION TO HEALTH.—Under the auspices of the Women's Union, C.E.I.S., four lectures to ladies upon the Medical Aspect of Alcohol in Relation to Health will be given on Nov. 8th, 15th, 22nd, and 29th, at 3.30 P.M. The first two by Dr. E. Symes Thompson, at 83, Lancaster Gate, W. The last two by Dr. Oliver Leeson, at the Vestry Hall, Kensington High-street.

THE DENTISTS ACT.—The Sheriff of Edinburgh has imposed a fine of £5 on a person charged with having, though not a registered dentist, during January last issued a circular in which he used words implying that he was registered under the Dentists Act, and having, during part of last year, a brass plate on his front door bearing the word "dentist"; and also by an advertisement implying that he was registered.

DUBLIN HOSPITAL SUNDAY.—The eleventh annual collection in aid of the Dublin Hospitals will take place on next Sunday, the 9th inst. The movement commenced in 1874 when a sum of £3306 was obtained, and during the ten years that it has been in operation the money contributed has amounted to £40,060, or an average of about £4000 a year. Of this sum £37,559 has been distributed among the various participating hospitals, showing that the cost of utilising the sums obtained causes an expenditure of about £200 a year, or five per cent. on the total.

THE PARKES MUSEUM.—The new session of the Parkes Museum will commence on November 13th, when Mr. G. J. Symons, F.R.S., will give a discourse on "The Relations between Meteorology and Hygiene," which will be illustrated by the instruments in use in a meteorological observatory. On November 27th Dr. Alfred Carpenter will read a paper "On the Advantages of Co-operation in the Progress of Hygiene," and on December 11th Mr. W. Eassie, C.E., will give a lecture "On Systems of Domestic Hot-water Supply." The meeting will commence on each evening at 8 P.M.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION.—At the quarterly meeting of this Association, held at Bethlem Hospital on Wednesday, Nov. 5th, under the presidency of Dr. Rayner, Dr. Julius Mickle exhibited cases of aneurysm and Dr. Savage a case of localised brain disease. A paper by Mr. Bonville Fox, on "Exaltation in Chronic Alcoholism," adjourned from a previous meeting, was then taken and discussed in connexion with the kindred questions of insanity arising from the use of opium and Indian hemp. Dr. Savage read a paper on "Delirium Tremens Passing to Mania."

RADCLIFFE INFIRMARY, OXFORD.—At the quarterly court of the governors of this institution, held on the 29th ult., a report was presented from the Building Committee recommending extensive alterations and additions to the infirmary, the present wards being found deficient in size, light, and air. The architect's estimate of the cost was £5000, but it was advised that £7000 should be raised before the work was begun. The sum of £2500 will be received from the trustees of the fund raised for perpetuating the memory of the late Duke of Marlborough, and a munificent donor, whose name was not then divulged, has promised to pay half of the remaining cost. It was eventually agreed to refer the matter back to the Building Committee, to reconsider at what part of the infirmary buildings it would be most desirable to add a new block to contain forty beds, and the cost of such a block on two floors, and to report to a Special Court in November.

THE ORDER OF ST. JOHN OF JERUSALEM (ENGLISH LANGUAGE).—The annual report of this order, just published, gives a record of the general proceedings of the chapter during the past twelve months, and of the various special departments of the work, such as the St. John Ambulance Association; the award of medals for deeds of gallantry in saving life on land; the issue of diets to poor convalescents of hospitals in London and elsewhere, and the British Ophthalmic Hospital at Jerusalem, where the number of attendances for the year ending December last amounted to 11,343. There are also papers on the transport of the sick and injured, and on the ambulance arrangements of the metropolis on the outbreak of epidemics, read at the International Health Exhibition by Mr. John Furley and Mr. Barrington Kennett respectively, and a lecture by Baron Dr. Mundy, on the Necessity for Making Surgical Provision for Railway Accidents. The report of the St. John Ambulance

Digitized by Google

Association states that twenty-five new centres and numerous detached classes have been opened during the past year at home and abroad. During the year, 10,053 certificates of proficiency have been awarded—viz, 5621 to men and 4432 to women, making a grand total of about 82,000 certificates granted to date. Three courses of lectures have been held at six of the metropolitan police stations, and numerous meetings to aid the movement have been held. Instances are quoted in which medical men have testified to life having been saved and "first aid" otherwise efficiently rendered by certificated pupils, and the report concludes with details of the progress of the recently developed ambulance corps for the transport of the sick and injured, and an interesting narrative by Lady Brassey of Ambulance Work in the West Indies.

ACADEMY OF MEDICINE IN IRELAND.—The following office-bearers have been elected for the ensuing year:—President: J. T. Banks. General Treasurer: R. McDonnell. General Secretary: W. Thomson. Medical Section—President: F. R. Cruise. Council: J. H. Benson, G. F. Duffey, J. Magee Finny, T. W. Grimshaw, R. A. Hayes, Henry Kennedy, J. W. Moore, W. G. Smith, H. C. Tweedy. Secretary: Alexander Nixon Montgomery. Surgical Section—President: E. H. Bennett. Council: Wm. Colles, C. Coppinger, E. Hamilton, E. Dillon Mapother, E. Stamer O'Grady, W. T. Stoker, P. J. Hayes, H. R. Swanzy, Kendal Franks. Secretary: William Stokes. Obstetrical Section—President: Lombe Atthill. Council: J. A. Byrne, Professor Dill, A. J. Horne, J. R. Kirkpatrick, George H. Kidd, Arthur Macan, T. M. Madden, R. D. Purefoy, William J. Smyly. Secretary: William Cox Neville. Pathological Section—President: A. Foot. Council: P. S. Abraham, J. W. Beatty, A. H. Corley, Samuel Gordon, J. V. Lentaigne, T. E. Little, J. M. Parser, F. B. Quinlan, W. Stoker, J. B. Storey.

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the October meeting of the Faculty, the following list of office-bearers for the year was declared:—President: Dr. Andrew Fergus. Visitor: Dr. Henry Muirhead. Councillors: The President, *ex officio*; the Visitor, *ex officio*; the Treasurer, *ex officio*; Dr. R. Scott Orr, Dr. T. Lapraik, Dr. Jas. Christie, Dr. R. Perry, and Dr. J. Morton. Treasurer: Dr. J. D. Maclaren. Honorary Librarian: Dr. James Finlayson. Vaccinator: Dr. Hugh Thomson. Board of Examiners: Dr. A. Lindsay, Chemistry; Dr. Hugh Miller, Midwifery; Mr. H. E. Clark, Anatomy; Dr. James Stirton, Midwifery; Dr. J. Wallace Anderson, Medicine and Materia Medica; Dr. P. A. Simpson, Medical Jurisprudence; Dr. James Dunlop, Surgery and Surgical Anatomy; Mr. David C. M'Vail, Physiology; Dr. Alex. M. Buchanan, Anatomy; Dr. H. C. Cameron, Surgery and Surgical Anatomy; Dr. William J. Fleming, Physiology; Dr. William Macewen, Surgery and Surgical Anatomy; Dr. Robert Perry, Chemistry; Dr. Samson Gemmell, Medicine and Materia Medica; Dr. Eben Duncan, Medical Jurisprudence and Hygiene.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

ALLRIGHT, FRED. WILLIAM, L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer and Public Vaccinator for the Wooburn District of the High Wycombe Union, vice Warren.

BLACKER, ERNEST, L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer to the Workhouse, Clutton Union, vice Perrin, resigned.

COLLIER, M. P. MAYO, M.B.Lond., F.R.C.S.Eng., has been appointed Assistant-Surgeon to the North-West London Hospital.

COLTART, WILLIAM WILSON, L.R.C.P.Lond., M.R.C.S., has been reappointed Medical Officer and Public Vaccinator for the Headley District of the Epsom Union.

COX, WILLIAM ALFRED, M.R.C.S., L.S.A.Lond., has been reappointed Medical Officer for the Banstead District of the Epsom Union.

DURHAM, FREDERIC, M.B.Lond., F.R.C.S.Eng., has been appointed Senior Surgeon to the North-West London Hospital.

DWYER, F. CONWAY, M.D., B.Ch.Dub., has been appointed House-Surgeon to the Mater Misericordiæ Hospital, Dublin, vice Cruise, resigned.

GORDON, JAMES, M.D., L.R.C.S.Ed., has been appointed Parochial Medical Officer for Aberdeen, vice McCrombie, deceased.

HALL, W. WINSLOW, M.B., C.M.Ed., has been appointed Resident Medical Officer to the Kilburn, St. John's-wood, and Maida-vale General Dispensary.

HAYDEN, W. C., L.R.C.P.Lond., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer to the Bishopstone District of the Wilton Union, vice Jones, resigned.

HEWITT, FREDERIC W., M.B.Cantab., M.R.C.S., has been appointed Administrator of Anæsthetics to Charing-cross Hospital.

HOOD, DONALD WILLIAM CHARLES, M.D.Cantab., M.R.C.P.Lond., has been appointed Senior Physician to the North-West London Hospital.

JENNINGS, CHARLES EGERTON, F.R.C.S.Eng., has been appointed Assistant-Surgeon to the North-West London Hospital.

KOCH, W. V. M., M.B., C.M.Ed., has been appointed Assistant Medical Officer to the Hull Borough Asylum.

MACKINTOSH, GEORGE DOUGLAS, L.K.Q.C.P.I., has been appointed Medical Officer for the Sixth District of the Market Harborough Union, vice Macaulay.

MARTIN, THEODORE, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Camley District of the Clutton Union, vice Perrin, resigned.

MENZIES, J. HERBERT, M.R.C.S., L.S.A.Lond., has been appointed House-Surgeon to the West London Hospital.

PEDLEY, FREDK. NEWLAND, M.R.C.S., L.D.S., has been appointed Dental Surgeon to the North-West London Hospital.

SHAW, JOHN, M.D.Lond., M.R.C.P.Lond., has been appointed Senior Assistant-Physician to the North-West London Hospital.

STEELE, RICHARD, L.R.C.P.Ed., M.R.C.S., has been appointed Visiting Medical Officer for the Cottage Homes for Children, Leicester Union.

TAYLOR, ALFRED EVERLEY, L.R.C.P.Ed., L.R.C.S.Ed., L.S.A.Lond., has been appointed Second Assistant Medical Officer to the County Asylum, Stafford, vice W. E. Ranson, M.R.C.S., L.S.A.Lond., resigned.

TREVES, EDWARD, M.R.C.S., has been appointed additional Honorary Surgeon to the Throat and Ear Dispensary, Brighton.

Births, Marriages, and Deaths.

BIRTHS.

EXHAM.—On the 13th ult., at Lucknow, the wife of Surgeon-Major R. Exham, Medical Staff, of a son.

HALEY.—On the 27th ult., at Claremont House, Market-street, Wakefield, the wife of W. H. Haley, L.R.C.P. &c., of a daughter.

HICKLING.—On the 24th ult., at Malta, the wife of T. Hickling, Surgeon, Q.G.S., of a son.

KINCH.—On the 28th ult., at Ash, Sandwich, the wife of G. H. Kinch, M.R.C.S., L.R.C.P.Ed., of a daughter, stillborn.

LACY.—At The Cottage, Sunninghill, Ascot, the wife of A. Gairdner Lacy, L.R.C.P.Lond., M.R.C.S., of a son.

MEYERS.—On the 27th ult., at Richmond Villa, Lordship-lane, Wood-green, the wife of Herbert H. Meyers, L.R.C.P., M.R.C.S., of a daughter.

PAYNE.—On the 31st ult., at Wimpole-street, Cavendish-square, the wife of Joseph Frank Payne, M.D., of a daughter.

TEW.—On the 27th ult., at Bulwell, Nottingham, the wife of James Scott Tew, Surgeon, of a son.

WILLIAMSON.—On the 1st inst., at Settle, Yorks, the wife of Richard Ernest Williamson, M.B., of a daughter.

MARRIAGES.

BLOUNT—PLEYDELL.—On the 4th inst., at All Saints', Margaret-street, by the Rev. John D. Bally, Arthur Blount Blount, M.R.C.S., L.R.C.P., L.S.A.Lond., elder son of James William Blount, of the Priory, Penge, to Isabel Constance, only daughter of John Cleeve Pleydell, of Holford-square, London.

LANE—BRISCOE.—On the 26th ult., at Christ Church, Wanstead, William Arbuthnot Lane, M.S., F.R.C.S., of St. Thomas's-street, S.E., eldest son of Brigade-Surgeon B. Lane, to Charlotte Jane (Lottie), youngest daughter of the late John Briscoe, Esq.

MAXWELL—SUCKLING.—On the 29th ult., at the Parish Church, Edgbaston, Warwickshire, by the Rev. G. F. B. Cross, assisted by the Rev. J. Canning, Patrick William Maxwell, M.B., M.R.C.S., of 10, Lower Mount-street, Dublin, to Elizabeth Catherine, daughter of Cornelius Benson Suckling, M.D.

OSBORN—BOYD.—On the 30th ult., at St. George's, Hanover-square, Sam Osborn, F.R.C.S., of Datchet, and Maddox-street, W., to Elizabeth, youngest daughter of the late Robt. Boyd, F.R.C.P., of Southall-park, Middlesex, and Bolton-row, Mayfair.

TAYLOR—MANBY.—On the 31st ult., at the Parish Church, East Rudham, Norfolk, Fredk. Taylor, M.D., F.R.C.P., of St. Thomas's-street, Southwark, eldest surviving son of David Taylor, M.R.C.S., to Helen Mary, younger daughter of Frederic Manby, M.R.C.S., of East Rudham.

DEATHS.

BROWN.—On the 23rd ult., at Rochester, John Dan Brown, M.D.Ed., aged 66.

BURTONSHAW.—On the 21st ult., at De Beauvoir-road, N., Thomas Burtonshaw, M.R.C.S., aged 32.

KAY.—On the 21st ult., drowned while bathing at Mablethorpe, Alfred Kay, L.R.C.P.Ed., L.R.C.S.Ed., of South Lincolnshire, aged 34.

LUMGAIR.—On the 1st inst., at Largo Cottage, George Lumgair, M.D., L.R.C.S.E., J.P. for Fifeshire.

RANSOM.—On the 4th inst., Peter Parker Ransom, for thirty-eight years Surgeon, at North Elmham, Norfolk, after a few days' illness, aged 64.

RIMELL.—On the 3rd inst., at Eardley-crescent, South Kensington, Thomas William Rimell, L.R.C.P.Ed., M.R.C.S., late R.N., aged 64.

ROGERS.—On the 27th ult., at The Strand, Exmouth, Nathaniel Rogers, M.D., in his 77th year.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, November 10.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations 10½ A.M. each day, and at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M
MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. de Havilland Hall: A Case of Surgical Scarlet Fever (postponed).—Mr. Rogers Harrison: A Case of Spontaneous Amputation.—Dr. Carrick: The Manufacture and Uses of Koumiss in Russia.

Tuesday, November 11.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 P.M., and Thursdays at 2 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ANTHROPOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND.—8 P.M. Mr. Francis Galton, F.R.S.: The Anthropometric Laboratory at the late Health Exhibition.—Mr. H. O. Forbes, F.Z.S.: Ethnological Notes on the People of the Island of Buru.
ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Dr. Champneys: Expiratory Emphysema—that is, Emphysema of the Neck, occurring during Labour and during Violent Expiratory Efforts; an Experimental Inquiry.

Wednesday, November 12.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.—Ophthalmic Operations on Tuesdays and Thursdays, at 1.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1½ P.M.—Skin Department: 2.30 A.M., on Tuesdays and Fridays.
ST. THOMAS'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.
LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.
GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations 2½ P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour.—Skin Department: 1.45 P.M., and on Saturday at 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M.
HUNTERIAN SOCIETY.—7.30 P.M. Council.—8 P.M. Dr. Collis: Observations on the Diagnosis of Small-pox.—Dr. Turner: A Case of Suppuration of Simple Fracture of Rib, with Remarks on the Etiology of Inflammation.
ROYAL MICROSCOPICAL SOCIETY.—8 P.M. Mr. G. Massee: Life History of Millowia Nives.—Professor F. Jeffrey Bell: Structural Characters of Spines of Echinoidea. I. Cidaridæ.—Mr. T. B. Rosseter: The Gizzard of Larva of Corethra Plumicornis.—Dr. J. D. Cox: Structure of the Diatom Valve.—Mr. Lewis Wright: New Lantern Microscope.
EPIDEMIOLOGICAL SOCIETY OF LONDON.—8 P.M. Inaugural Address by the President (Dr. Norman Chevers): Certain Rare Epidemics and Endemics.

Thursday, November 13.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M
ST. BARTHOLOMEW'S HOSPITAL.—1½ P.M. Surgical Consultations.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M
CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.
NORTH-WEST LONDON HOSPITAL.—Operations, 2½ P.M.
OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—9 P.M. Mr. Jonathan Hutchinson, F.R.S.: The Relation of Gout to Eye Disease (Bowman Lecture).

Friday, November 14.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1½ P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 2 P.M.
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.
CLINICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Stephen Mackenzie: Cases of Dysentery treated by Voluminous Injections of Nitrate of Silver.—Mr. Morrant Baker: Three Cases of Joint Disease in connexion with Locomotor Ataxy.—Dr. H. B. Donkin: A Case of Muscular Atrophy and Joint Disease.—Dr. Hale White: A Case of Tumour of the Frontal Lobe with very few symptoms.—Living Specimens: A Case of Favus, by Mr. Malcolm Morris. Cases of Joint Disease illustrating Mr. Baker's and Dr. Donkin's papers will be present, and perhaps others.

Saturday, November 15.

KING'S COLLEGE HOSPITAL.—Operations, 1 P.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

TO OUR CONTRIBUTORS.

WE do not propose to publish this year a list of intending contributors to our volumes for 1885. The response to our annual circular has in the past been so liberal that we have with difficulty been able to keep pace with the supply of papers and communications with which we have been favoured. We shall be glad, however, to receive, for private record, the names of medical officers of public institutions, as well as of physicians and surgeons in private and general practice, who are desirous of furnishing us with clinical lectures and reports of cases of interest for our forthcoming volumes.

ANÆSTHETICS IN DENTAL PRACTICE.

A Junior.—Nitrous oxide gas has been proved beyond all doubt to be the safest of anæsthetics in the hands of skilful administrators. The only drawbacks to its use are the shortness of its effect and the costliness of the necessary apparatus; but for anæsthesia during tooth extraction nothing can be simpler or better. Complete instructions as to its use for this purpose will be found in Coleman's Manual of Dental Surgery; but a few visits to a hospital where it is frequently given would be the best means of learning to administer it safely.

A Young Practitioner.—The case should be treated by dilating, and then, if necessary, curetting the whole of the inner surface of the uterine cavity.

Spes.—See Bellamy's Surgical Anatomy.

Enquirer.—Our correspondent should put Mr. So-and-So, appending his titles.

STRANGE MIGRATION OF A NEEDLE.

To the Editor of THE LANCET.

SIR,—About the end of November, 1883, a lady called upon me, stating that the greater portion of an ordinary sewing-needle had broken in the first joint of her left thumb. I remember having felt the needle point, and, after ineffectual attempts at its extraction, having advised my patient to let it alone, lest the attempt to remove it might result in greater injury to the joint. A few days ago the patient called upon me to inform me that a day or two previously she felt a pricking sensation in the right forefinger, and, having broken the skin, she without difficulty removed the greater portion of the lost needle from the point of the finger. The point of it was quite clear, the remaining portion rusty. Of all the strange journeyings of needles in the flesh this is the strangest which has fallen under my observation.—Yours truly,

Glasgow, Nov. 3rd, 1884. D. CAMPBELL BLACK.

Mr. Leonard.—Compliance with the request would, we fear, lay us open to too many applications of a similar kind.

Dr. Golaub Sing.—The pamphlet has been received.

M.B. EXAMINATION, UNIVERSITY OF LONDON.

To the Editor of THE LANCET.

SIR,—The following question is one of six in Midwifery and Diseases of Women submitted to the pass candidates at the examination which is now being held at Burlington-gardens:—"Give the anatomy and treatment of a case of unilateral hæmatokolpos (retention of menses)." May I be allowed to ask you, Sir, if this condition, "unilateral hæmatokolpos," is so frequently met with that every pass M.B. candidate should be supposed to have met with it, and to know all about it? Or is it merely an ingenious crux that has been set by a dyspeptic examiner?

I am, Sir, yours faithfully,

Nov. 5th, 1884. IGNORAMUS.

THE KING OF ITALY'S CHOLERA TOUR.

THE following inscription, from the pen of Professor Domenico Gnoli, will be inscribed on the tablet about to be placed in the Capitol in commemoration of King Humbert's visit to cholera-stricken Naples :—

S. P. Q. R.
A RICORDARE AI POSTERI
CHE RE UMBERTO I
NEL SETTEMBRE DEL 1884
ACCORREVA A NAPOLI
AFFLITTA DA EPIDEMIA COLERICA
RECANDO NEGLI OSPEDALI E NE' TUGURI
CORAGGIO, CONSOLAZIONE, SOCCORSO
E VI RESTAVA FINCHÈ IL MORBO NON DECLINASSE
FRA LE BENEDIZIONI DI TUTTA ITALIA
PER LUI TREPIDANTE,
ROMA
LIETA DI RISALUTARLO INCOLUME,
SUPERBA DEL SUO RE,
INTERPRETE DELLA RICONOSCENZA UNIVERSALE
POSE.

(*Translation.*)

THE ROMAN SENATE AND PEOPLE.
TO RECORD TO POSTERITY
THAT KING HUMBERT I.
IN THE SEPTEMBER OF 1884
HASTENED TO NAPLES,
IN HER AFFLICTION FROM EPIDEMIC CHOLERA,
BRINGING INTO HER HOSPITALS AND HOVELS
COURAGE, CONSOLATION, RELIEF,
AND, UNTIL THE SCOURGE ABATED, REMAINED THERE
AMID THE BLESSINGS OF ALL ITALY
TREMBLING FOR HIM.
ROME,
REJOICING TO SALUTE HIS SAFE RETURN,
PROUD OF HER KING,
INTERPRETING THE UNIVERSAL GRATITUDE,
PLACED THIS TABLET.

Truth.—The amended circular on the subject of examination previous to promotion having removed what appears to us to have been the principal objection to that measure, we do not think it necessary to publish our correspondent's letter. We would refer him to the annotation on the subject in our last number.

Octavius has not enclosed his card.

M. D.—How can a person rightly add "M.D." to his name when he does not possess that degree?

OPENING THE TRACHEA.

To the Editor of THE LANCET.

SIR,—Such sad occurrences as the deaths of Drs. Foulis and Rabbeth must force upon the medical profession the question of right and wrong in the treatment of diphtheria by tracheotomy. It is a very grave question whether the stimulus to heroism given by so brilliant an example is worth the sacrifice of so much cultured energy. I have not yet heard of a child's life having been saved, but I have heard of several good men having sacrificed themselves. Even the performance of the operation is often a question of doubt, and a painful question for a surgeon to decide. In those cases which have come under my notice I have explained the case as fairly as I could to the parents, and I only urged an operation strongly in one case. It has appeared to me that when there are signs of bronchial, and more especially pulmonary, mischief (and very often there are), opening the trachea would be merely palliative treatment, and would only prolong a consciousness which deficient oxygen and blood-poisoning had almost abolished. Out of six cases which I saw during an epidemic in this place only one appeared to me to be a fair case for tracheotomy, there being slow development of the disease, which seemed purely laryngeal for days. In that case the parents refused the operation. A suction syringe to fit a tracheotomy tube might easily be a part of a tracheotomy case; but in many cases would it not be better to use no tube at all, simply dilating the tracheal opening? A freer vent would apparently be thus given to false membranes. Mr. Eddowes performed tracheotomy in one of my cases, and we had great difficulty in keeping the tube clear from the very tenacious secretion. Boiling water only would remove it. The whole question is full of difficulties, and every case must be modified by individuality and surrounding circumstances; but a discussion of the matter in your columns might do much to instruct and assist.—Yours truly,

Loughboro, Oct. 24th, 1884. J. B. PIKE, F.R.C.P.E., M.R.C.S.E.

To the Editor of THE LANCET.

SIR,—In the performance of tracheotomy for diphtheria, would it not be well to have at hand a twenty- to thirty-ounce bottle, exhausted as for aspiration, fitted with a rubber cork, the free extremity of the attached tube having something twisted round it to make it fit tightly the lumen of the tracheotomy tube—a piece of rubber tubing, for instance? The turning of the proper stopcock would answer in place of the hazardous suction which has already cost our profession so dear. Should this not clear the tube it would at least bring the obstructing membrane within reach of forceps.—I am, Sir, yours faithfully,

Oct. 27th, 1884. A. D. M.

AREA AND POPULATION OF NEW SOUTH WALES CONTRASTED.

FROM information issued from the Immigration Office, New South Wales, it appears that, giving a square yard as standing-room to one individual, the whole population of the Colony could be placed on a little over 156 acres, or less than a quarter of a square mile, and the area of the Colony is 316,320 square miles in extent. The density of the population of England is nearly 400 to the square mile, giving only about an acre and a half to each individual; while there are nearly 270 acres to every man, woman, and child in New South Wales, which, if as densely populated as England, would have a population of about 135 millions.

W. B. T.—We are unable to give our correspondent a definite answer to his question, or the reference which he desires. But it has long been a popular, though probably groundless, belief that the wearing of ear-rings is beneficial to the eyesight.

Mr. Mercer (Bath).—The paper has been received.

Medicus (Dublin).—On our second page of contents will be found a reference to the vacant appointments advertised in our columns.

"THE VENTILATION OF DRAINS AND SEWERS BY SHAFTS."

To the Editor of THE LANCET.

SIR,—I read with some interest, in your issue of Oct. 11th, an article under the above heading. On many points I agree with the opinions therein expressed; but I cannot admit that the evils which undoubtedly obtain are chiefly owing to the line adopted by "engineers" and "other professional men." The folly referred to, when practised "for the sake of a little economy," emanates almost invariably from the "owner or authority," who does not properly appreciate the money value of proper precautions in sanitary matters, and is not brought about by the engineer, who can have no possible interest in undue or false economy.

Having reference to the ventilation of public sewers, it is well understood that where sewers are properly designed and adequately supplied with means of flushing, very little effluvium, and less, if any, poisonous gas, will exude from the surface ventilators. Some engineers are to blame for being too easily satisfied with sewer velocities inadequate to ensure the rapid passing away of the foul matters before putrefaction sets in and gas is generated. To proper falls in the sewers must be added a plentiful supply of water to work them, or stagnation of sewage, the prime origin of the evils complained of, will result. Water in proper quantities not only ensures a sufficient flow to obtain in practice the theoretical velocity due to the particular size and gradient of the sewer, but, by lowering the temperature of the sewage and of the air in the sewer, it checks or delays the progress of putrefaction.

Admitting all this, however, it is to be feared that in practice sewers will continue to be so laid and dealt with as to produce noisome odours, if nothing worse; and it has long been apparent that something better than simple unaided ventilation at surface level should be adopted. The increased safety afforded by high ventilators over surface ventilators may be taken as unquestioned by engineers, but in attempting anything like a general introduction of the system they are brought face to face with a considerable difficulty. Engineers abreast of the age recommend ample surface ventilation, supplemented where practicable by high-level outlet ventilators; but the real bar to the wider adoption of a safer and better system of ventilating public sewers is the absence of statutory power to enable local authorities to place such shafts on private property, and the objection evinced by house owners to ventilating-shafts being attached to their buildings.

It is not easy to suggest a sufficient remedy without risk of interference with private rights; but if the powerful influence of THE LANCET were successfully exerted to obtain such an amendment of the Public Health Acts as to vest in sanitary authorities the necessary powers to render high-level ventilation practicable, sanitary science and the resources of engineers would, I venture to say, be found equal to the rest. The most thorough system of ventilation for sewers would be effected by forming them of a trough open up to the surface level. The introduction of this system has hitherto been precluded by considerations of expense. It is, however, possible to arrange a design of this nature at a cost not altogether beyond the range of possibility, and a material saving in many items of construction would be effected. There is undoubtedly far greater danger in sewer gas reaching the inside of houses than can obtain from gas dispersed in the open air of the streets; and, moreover, air or gas forced into a house in consequence of insufficient ventilation is obviously far more noxious than that emanating from a sewer freely ventilated. Public sewers must be ventilated to no less a degree than by the systems now in vogue, and if high shafts are to be entirely substituted for surface ventilators, they must be of such adequacy as to ensure no more pressure being exercised than at present upon the main intercepting trap between the public sewer and houses, and no less frequent change of air being in the sewer. To enable this to be done, the public must either submit to the somewhat novel, though unobjectionable, shaft being placed on their property, or pay the extra cost entailed by putting up shafts otherwise sustained. While, however, we are waiting for necessary powers, the most should be made of present circumstances. With proper care sewers may be so designed as to render the nuisance arising from surface ventilators very slight, and any actual danger remote.

I am, Sir, your obedient servant,

URBAN SMITH, A.M.I.C.E.

Westminster-chambers, S.W., Oct. 27th, 1884.

VACCINATION IN TENNESSEE.

WE are much obliged to Dr. O. C. Tite (?) of the Hermitage Club, Nashville, Tenn., for his admirable letter on the question of vaccination, as presented to his mind in the epidemics of Tennessee. It entirely coincides with the experience of all sensible men in all communities, and, indeed, is a repetition of what is monotonously found everywhere. The letter should be published broadcast, but would be superfluous to the readers of THE LANCET. It shows that even if there were no Compulsory Vaccination Act, there is another force to drive men to the vaccination station more imperious still—viz., the terrible disease of small-pox, from which it is the only protection, perfect or imperfect, according as it is done perfectly or imperfectly.

Dr. Jas. Wilson.—1 and 2. The idea entertained by hairdressers is that the hair is a hollow structure, and the cutting of the ends causes them to "bleed" nutriment, and that singeing stops this and "heals" the ends.—3. The operation is founded on an entirely mistaken idea of the structure of the hair.—4. It is of modern introduction, and originated outside the profession.

Mr. E. Chesshire.—The notice appeared in THE LANCET of Oct. 25th, page 758.

THE LATE DR. RABBETH.

To the Editor of THE LANCET.

SIR,—Sir Wm. Gull, in commenting on the heroism and subsequent sad fate of the late Dr. Rabbeth, suggested that a memento of his devotion should be perpetuated by annually presenting a medal to some distinguished Bachelor in Medicine of London University.

May I suggest that those who are known to have previously performed an exactly similar act of bravery and humanity, and without thought of recompense or recognition, should at least be also considered worthy recipients of such an honour? A case occurs to my recollection, very similar, except in the subsequent results, to that which was performed by Dr. Rabbeth. It was about the year 1868. I had to perform tracheotomy in a very urgent case of laryngeal diphtheria. While dividing the rings of the trachea a small vessel from the edge of the wound began to bleed rather freely, blocking up the windpipe, and threatening immediate suffocation. Mr. Arthur H. Sandiland, then a student at St. Bartholomew's Hospital, who was assisting myself and partner, Dr. F. H. Daly, in the operation, with a promptitude and coolness which elicited the admiration of all present at the time, at once seized a tube or pipette, and cleared the windpipe by suction, so that the tube could be inserted, thus probably prolonging the life of the little patient in apparent comfort for several days. My late partner and myself have often since referred to the cool courage and unselfish heroism of Mr. Sandiland, conduct which will be regarded by those who know him as quite characteristic of the man.—I am, Sir, yours truly,

Kingston, Nov. 4th, 1884. GEORGE MUNDIE.

A MEDICAL HERO.—DR. RABBETH.

In trying to save a patient's life he lost his own.

No nobler gift at heaven's gate
Could mortal ever give;
Angels, approving, whispered,—
"He died that she might live!"
And though our hopes are broken,
And mothers weep full sore,
We pray that both are happy—
Not lost, but gone before.

Cley-next-Sea, Norfolk, Nov. 4th, 1884. W. SUMPTER, M.D.

M.R.C.S.E., J.P., &c.—A reference to our issue of Aug. 9th last will show that the name mentioned has been removed from the roll of the Royal College of Surgeons of England.

Mr. R. L. Albert.—We cannot find space for the continuation of the discussion.

SANITARY CONDITION OF CANNES.

To the Editor of THE LANCET.

SIR,—My early arrival at Cannes has enabled me during the last week to visit the whole of this health resort, and it is with pleasure and satisfaction that I am able to give you a favourable account of the sanitary condition of this locality. The streets, squares, and quais are perfectly clean, being constantly swept and watered. The street gulleys are most of them trapped, and the openings are painted with a thick coating of chloride of lime. The narrow streets I have also visited, and find that many of the houses are being whitewashed and painted. The hotels and villas are for the most part cleaned, and prepared to receive visitors, while some of the former are still in the hands of the painters and whitewashers. The gardens are being weeded and made tidy. On visiting the hotels the first subject mentioned, and spoken of with much pride, was the new arrangements for drainage; and I was glad to see the stamp of English manufacturers on the sanitary appliances, which were in perfect working order. The change for the better since my visit to Cannes four years ago is very great. No doubt the typhoid scare of three years ago has done a vast amount of good to Cannes and its inhabitants, and, what is still better, they all recognise it. The weather is very fine; bright sun, blue sky, with the thermometer steady at 68° F. A few good showers of rain are required, to wash the dust from the trees and brighten up the general aspect.

I am, Sir, yours truly,

Cannes, Oct. 20th, 1884. G. H. BRANDT, M.D.

Gorgius.—Sect. 29 of the Births and Deaths' Registration Act, 1874 (37 and 38 Vict., Cap. 88), enacts: "In case of the death of any person who has been attended during his last illness by a registered medical practitioner, that practitioner shall sign and give to some person required by this Act to give information concerning the death a certificate stating to the best of his knowledge and belief the cause of death." In the face of this enactment it must be clearly illegal to charge a fee for supplying a certificate which the Act declares shall be furnished. Moreover, it may be presumed that such a fee would only be paid by those who are unaware that the Act entitles them to have the certificate, for the purpose of the Registration Act, without the payment of fee or reward.

Dr. Jas. Russell (Glasgow).—The publication of the correspondence forwarded to us would probably bring about a controversy for which we have not space.

Mr. Molony (Slingsby).—Yes.

Mr. J. Barnes.—Cassell's Domestic Medicine; Wood's Household Practice of Medicine.

Mr. Henry Crosse.—We regret we cannot afford the desired information.

WASHING OUT THE BLADDER.

To the Editor of THE LANCET.

SIR,—Mr. G. B. Browne suggests, in your issue of the 18th ult., a means of washing out the bladder by the use of an ordinary indiarubber pump. I beg to mention a method first adopted by myself in a case of malignant disease, and found very convenient—viz., an indiarubber tube, such as is used for infants' feeding-bottles, only about eight feet long. One end may be attached to the plug, A B, described by Mr. Browne, and the other end passed over a small tube fixed in a leaden weight of two or three ounces. This weight may be placed in a small pail containing the medicated solution hanging by a cord passed through a hook in the ceiling. By means of a cord the reservoir may be raised or lowered, thereby increasing or diminishing the force of the stream. The patient is free to move about within certain limits, and the hands are more free; in a sensitive organ there is less danger of causing pain from movement of the instrument; the flow may be arrested by simply pressing the indiarubber. The stream, after the weight and reservoir are in position, may be readily caused to flow by rolling a bottle over a few inches of the tube towards the opening of exit. There is nothing startling in the above method; and although I have never seen it used but by myself, I do not claim any great originality in it. A trial of this cheap apparatus with a "double tube" catheter will prove its efficiency.

I am, Sir, yours truly,

Oct. 27th, 1884. BEAVER.

A RARE CASE.

To the Editor of THE LANCET.

SIR,—There is at present in this asylum a male patient who is mentally the subject of chronic mania, and physically suffering from phthisis (left lung). For several months past there has been a persistent, distressing cough, and the daily amount of expectoration has been enormous. About a week ago a small abscess appeared between the sixth and seventh ribs, just external to the nipple-line, the contents of which had very soon a free outlet without the aid of a bistoury. It was evident it had a direct communication with the pleural cavity, and over a pint and a half of grumous material escaped from the pleural space when the abscess opened, and small quantities continue to ooze from the sinus when the dressing is changed. There is now no cough or expectoration, and the patient has gained strength.

I shall be pleased to know if any of your readers have met with a similar case. I am, Sir, yours truly,

Dorset County Asylum, Oct. 28th, 1884. P. W. MACDONALD, M.B.

Mr. J. W. Sheppard and *Subscriber.*—The treasurer is Dr. Claye Shaw, Bansted Heath Asylum.

Mrs. C. E. Field.—We cannot interfere in the case.

"AN APPEAL TO PUBLIC VACCINATORS."

To the Editor of THE LANCET.

SIR,—Dr. Scoresby-Jackson does not seem to be aware that there has been an official declaration of the area of scar to be produced by primary vaccination, and that this may be obtained by any number of insertions the vaccinator may deem sufficient. The Board inspectors require an area of half a square inch, which is about the size of a sixpence. In practice I have found three free insertions sufficient; and as I received two grants for successful results while I was a public vaccinator in a country district some years ago, I conclude that my method was sufficiently effectual to satisfy the experienced eye of the inspector. I may add that I have never seen an attack of small-pox in any case in which I had performed primary vaccination with such results as above given. I am, Sir, yours truly,

Nov. 3rd, 1884. JAMES THOMPSON, M.D.

OBJECTIVES.

To the Editor of THE LANCET.

SIR,—In opticians' list of objectives there are often several of the same power, but at different prices, some being even twice as much as others. May I ask your correspondent, Dr. Griffin, who seems to have gone into the subject closely, whether the value of an objective to a practical worker is in mere proportion to the price; or which class would be most serviceable for histological work?—Yours obediently,

Oct. 28th, 1884. A STUDENT.

Dr. Ormsby.—As we did not give currency to any of the statements of which our correspondent complains, we do not feel called upon to insert his long explanatory letter. If he has been misrepresented, he should address his disclaimer to the journal in which the previous letter and the commentaries upon it appeared.

Mr. Gem.—The report will appear in our next.

Mr. Pike (Loughborough).—Yes.

THE PRELIMINARY EXAMINATION.

To the Editor of THE LANCET.

SIR,—I hope the medical profession as a body will condemn Dr. Haughton's scheme for the Medical Preliminary Examination, which has made a ridiculously easy examination more easy still. The idea of being able to pass an examination with so simple and few subjects bit by bit is absurd. As it was, at the College of Preceptors many boys of twelve could have passed it with ease. Last year I knew men who, knowing no Latin before, and with very little other education, passed it with a few weeks' cramming. Now our examination will be easier than that of the F.P.S.Glasgow or the Edinburgh Preliminary, for they do insist on having two books of geometry. I knew a man go up to Scotland and pass in English only. The next time he crammed up and passed in Euclid, the next time in algebra and arithmetic, the fourth time in Latin, and the fifth time in chemistry. Thus, counting mathematics as one subject, he went up five times for four subjects; and this is what London is imitating. Alas, to what depths will the medical profession sink! I am, Sir, yours obediently,

Brixton, Oct. 29th, 1884. B.A.

THE M.D. DEGREE.

To the Editor of THE LANCET.

SIR,—I am in receipt of a letter from W. K. Hilton, Esq., M.A., of the University of Durham, informing me that at present that university is not desirous of any change in its regulations for the admission of practitioners to examination for its M.D. degree without residence. I am sure this decision will be received with regret by a large number of your readers. We can only hope that this may not be the final result.

I am, Sir, your obedient servant,

Leigh, Nov. 1st, 1884. B. JONES.

An Inaugural Address
ON THE
REVIVAL OF OVARIOTOMY,
AND ITS
INFLUENCE ON MODERN SURGERY.

Delivered at the Midland Medical Society, Birmingham, November 5th, 1884,

BY SIR SPENCER WELLS, BART.,
LATE PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

(*Concluded from p. 813.*)

BY careful consideration of all the sources of danger, and by successive improvements in practical details, the mortality of ovariotomy became less excessive; and it was soon felt that the mortality, after other surgical operations, both in London and provincial hospitals, as well as in private practice, was excessive, and ought to be diminished. It was some years after Southwood Smith, Edwin Chadwick, and William Farr had begun their attempt to impress the importance of a knowledge of sanitary science upon the people of England that its influence was much felt either in hospital practice or in domestic life; and I doubt whether the attention of surgeons was ever fully awakened to the possibility of reducing the mortality of great operations before Sir James Paget, at the meeting of the British Medical Association in London in 1862, delivered his memorable address upon the study of the large group of diseases confounded under the name of "pyæmia."

Two years afterwards, at Cambridge, I addressed the Association upon the same subject; and, after alluding to many sanitary measures, called attention to the bearing of the then recent researches of Davaine and Pasteur, and to the value of Polli's experiments upon the use of sulphurous acid and the alkaline and earthy sulphites in the prevention and treatment of many of the infectious and contagious causes of excessive mortality after operations. We were on the dawn of that phase of modern surgery when the so-called laws of sanitary science were tested in the laboratory by physiological chemistry and experimental pathology, and were afterwards acted on by Lister and his followers.

During this time of reaction and activity in abdominal surgery there was a corresponding development of the literature of the subject. It appeared in all shapes and came from all quarters. The names of men who have since become celebrated were ushered in with their first contributions. Essays and records of cases abounded in periodicals. Pamphlets fell thick upon the public and books were published which, though more or less incomplete, showed how fast material was accumulating for the future composition of elaborate treatises.

A review of all this matter poured out by the press, both English and foreign, on the question of ovariotomy, a few years before and after the date of 1865, enables us in a measure to gauge the extent of the interest the operation had excited, the change of opinion in reference to it, the success that had attended it, and to trace the indications which the reports contained of the spreading eagerness of the profession to seize every opportunity of giving to humanity the benefits which the practice was capable of conferring. But that which most forcibly strikes the attention in reading this literature is the contrast furnished by its tone and tendency with that which preceded and made way for the revival. Previously all that had been written was sceptical, doubting, speculative, or even prohibitory. Wavering expectation was modest in its demands, timid in its forecastings. There was more of fear than hope for the future. That future came, and with it the revival. Then, instead of the vague prophetic inspirations of the Hunters, the moving exhortations of Bell, the qualified and cautious encouragements of Blundell, the passive admissions of Astley Cooper that ovariotomy might be done, the conscientious shrinking, in an exalted reverence for the sanctity of human life, from the realisation of what seemed so desirable and within the compass of daring power, the pathetic wailings over sufferings unrelieved and deaths unresisted, and the despondency of professional inaction, we had reports of accomplishment which proved, by the wideness of their sources, their numerical importance, and the character of their authors, that the revival was assured. The question now changed from one of possibility to one of improvement, and reports of cases merged into discussions of practical details of operative and therapeutical interest. These, from their precautionary or conservative bearing, gave good augury of the vast ameliorations which we have seen within the last twenty years, and have brought us at the present time to nearly certain success when a careful surgeon operates in a favourable case. One may truly affirm that in all these outpourings of the revival period there was nothing vainglorious, boasting, presumptuous. As contributions to science they were serious, candid, plain, aiding further progress, informing to the profession, and useful to mankind. They bore upon them the signs of a wise resolution to advance circumspectly upon the path now open; and if tinged with a glow of the personal satisfaction which flows from a sense of duty in part fulfilled, and brightened with a gleam of the complacency reflected from the visible evidence, now so constantly before the public in the living, healthy survivors of the operation, that the profession as a corporate fraternity was equalling in its philanthropic energy that which had made the reputation and had been the pride and solace of its older "men of renown"—I can only say, not that it was excusable or admissible, but that this gratulation was no more than the circumstances prompted, or than may justly be felt by all who join in working, with a right mind and to a good issue, for the welfare of their kind.

And here with 1865 I may end this retrospect of the revival of ovariotomy, of a rapid revolution in opinion and practice in less than ten years. Before 1858 the operation, like all good things, had been of slow growth. One hundred years ago it was but a germ that might be described in a lecture by John Hunter. Ten years later it was seed that fell from the hand of Bell. In little more than another decade it germinated as a living vitalising reality in Kentucky. Sixty years ago it was transplanted to the land of its philosophical conception. In twenty years more we find it a sapling on English soil, growing slowly at first, and up to 1858 looking as if it might prove no more than a withering gourd. But by 1865 its root had struck firm, its stem stood erect, its branches were wide and strong, known and sought as a refuge by the sick and dying. That it was no withering gourd has been proved by all that the world has since seen. Thousands of perishing women have been rescued from death; many more thousands of years of human life, health, enjoyment and usefulness have been given to the race; and to all future victims of a malady before inevitable in its fatality, it gives consolation, hope, and almost certainty of cure.

And passing over another twenty years—advancing from 1865 to 1884—we can rejoice that in all our metropolitan and most of our provincial hospitals, and from the best teachers on both sides of the Atlantic, medical students of to-day may hear of the good already done—may see for themselves how success is attained, and possibly, by the establishment of some new fact, or the discovery of some new device, they may increase our power over disease, and carry on the work to our successors.

I must leave it to others to speak of our great hospitals and important schools. But I cannot close this part of my address without one word of hearty congratulation to my successors at the small hospital where, with seldom more than six or eight beds at my disposal, in twenty years I completed 408 cases of ovariotomy, the deaths having diminished in successive periods of five years from one in three to one in four or five, and in the last two years to one in ten. In seven years, 1878–83, my three successors among them had 496 cases—some ninety more than I did alone in twenty years,—the deaths falling from one in five in 1878 to one in eighteen in 1883. And the recent publication of my colleague Doran adds to the satisfaction I feel in seeing my operative work so efficiently continued, the pleasure of noting how happily he is supplementing the opening of his career as an operator by the intellectually higher distinction of being acknowledged as a penetrating investigator and clear expositor of the obscure subject of ovarian pathology, to which he is devoting his philosophical earnestness. On this centenary of Hunter's lecture we may truly claim that his example is followed, his foresight verified, and our exertions rewarded.

In asking you to consider the influence which the revi

Digitized by Google

of ovariotomy has had upon modern surgery, I think we may not only assume the revival as complete by the year 1865, but that, in the words of Paget, "the influence for good was not limited by the increased success of ovariotomy, but extended to every department of operative surgery, and will always continue to be felt in the whole practice of surgery." And the rapidity with which the success of ovariotomy led, again using Paget's words, to "an extension of the whole domain of peritoneal surgery," is not less remarkable than the rapidity with which ovariotomy had advanced in professional opinion between 1858 and 1865. The first extension naturally enough was to the removal of uterine tumours.

At first this was only done after a mistaken diagnosis; but before many years had passed it was done designedly. At first only in cases of pedunculated subperitoneal outgrowths; but latterly, under conditions most unfavourable, success has been obtained in a proportion of cases very surprising even to those who in their long experience have many times been astonished at their own success. Nothing in the whole history of surgery can be at the same time so gratifying and so astounding as the records of Keith's later cases of the removal of uterine tumours, collected and published by his son. Taken alone, they would almost justify a general law to the effect that no woman should be allowed to die of any innocent uterine growth without attempting to save her life by operation being made. When the earlier cases of Kœberlé were criticised in the French Academy by Boinet, Richet cautioned the audience against summary condemnation of an operation not dreaded more than ovariotomy was not long before. The question since that day has been decided by experience, and if a word of caution is now needed, it is only to warn surgeons of the future that they cannot hope for success unless they prepare themselves for operation upon the living body, by taking every available opportunity of practising upon the dead body, and by a conscientious determination to study rather the true welfare of the patient than, on the one hand, how to avoid responsibility, or, on the other hand, how to advance their own renown.

It is fortunate that in some of these cases of uterine tumour an alternative proposal ought to be considered. Both ovaries may be removed with the knowledge that this proceeding has been followed by atrophy of the uterine growth. This, on the part of Hegar, was the legitimate application of a principle, and the practice has often proved successful. In cases where removal of the tumour would have been impossible or exceedingly dangerous, removal of the ovaries and Fallopian tubes has led, with far less risk, to cessation of bleeding and more or less diminution of the morbid growth. But we must have further experience before we can arrive at a fair estimate of the relative value of the two courses of action. We have learned, however, that if the ovaries are not completely cleared away, if, having been adherent, they have been twisted or scraped away from their connexions, and some small portions left, menstruation may afterwards recur quite regularly, even though both Fallopian tubes have been totally removed. I have more than once warned the profession against the capricious extirpation of the ovaries, because they are supposed to be the source of all womanly ills, and I repeat my caution, seeing to what wide-spreading evils its neglect may lead. I think it a charity to lay a checking hand on an erring judgment before it has gone too far, and I would fain save our profession from the public odium which must sooner or later be the penalty suffered by all, if a few indiscreet members of our body act without general sanction, or disregard general disapproval.

I have not time to enter upon the very important question of the excision of the entire uterus, either by the vagina or by abdominal section, nor of that substitute for the Cæsarean section known as Porro's operation, nor on the operative treatment of extra-uterine fœtation; and can only say a very few words about the next kind of abdominal tumour, the removal of which followed the ovarian and uterine—the enlarged spleen. I did not meet with a case which I thought justified the operation until 1865, although I had long before that been determined to do it in any suitable case. My second case was performed in this town, and I have only met with one since. I need not tell you that the example has been frequently followed by other surgeons, and there is every reason to hope that increased experience may be followed by diminished mortality.

And so with renal and peri-renal tumours. Nephrotomy, nephro-lithotomy, pyelo-lithotomy, and nephrectomy, terms hardly entering into surgical literature twenty years ago, define operations which are now performed in increasing numbers, and, especially to the physiologist, with a wonderful success. My colleague, Knowsley Thornton, can boast of ten nephrectomies, all by abdominal section, as well as four nephrotomies, and three nephro-lithotomies, the whole seventeen cases successful. These cases, and seven successful cases of pyelo-lithotomy out of eight, as lately recorded by Anderson, can only be the effect of rigidly abiding by the observance of what we now know to be the rule and criterion of good work. So also with a variety of solid and semi-solid abdominal tumours, originating in the pelvic cellular tissue, or in the peri-renal fat, or in the mesentery, the appendices epiploicæ, the omentum, or the abdominal wall, extirpation is effected with a loss of life so small as would have been almost incredible a few years ago.

Already in several cases tumours formed by peritoneal hydatids have been successfully removed. I have not time to do more than barely allude to opening of the gall-bladder and the removal of gall-stones, the opening and draining of hepatic abscesses, of hydatid cysts of the liver, of pelvic abscesses, and of hæmatocele, to removal of the pylorus, gastrostomy, and opening of the stomach and removing a large mass of hair. In one remarkable case Mr. Thornton removed a mass of hair weighing two pounds, which was moulded into the shape of the stomach. The incision across the greater curvature was five inches long, and fifteen deep and fifteen peritoneal sutures were required to close it. The abdomen was closed, and the patient is perfectly well. Ten years ago such an account would hardly have been believed. With the exception of this and one successful case by Schönborn, in all other reported cases such masses of hair in the human stomach have only been found after death. But no one who has watched the progress of these operations, has considered the causes of death in fatal cases, and the details of the operative proceedings in successful cases, can come to any other conclusion than that one important element in the attainment of success is the scrupulous observance of the principles laid down as necessary to success in ovariotomy; not only as regards the hyglenic precautions never omitted in modern surgery, but especially as to the importance of a very accurate and exact union, not only of the edges, but of the surfaces of the peritoneal surface of the viscera and of the abdominal wall. In gastrostomy, for instance, it is found that when the stomach is attached to the abdominal wall by a single ring of sutures, the weak attachment may give way, and risk of extravasation into the peritoneal cavity may be great. But when, after dividing the abdominal wall, the parietal peritoneum is sewn to the skin all round the opening, a broad surface of visceral and parietal peritoneum may afterwards be maintained in contact by a circle of sutures, forming loops, passed through the peritoneal coat of the protruding portion of stomach, and through the whole thickness of the abdominal wall, about half an inch from the edge of the incision. Smaller fine sutures being inserted between the larger ones, a very close and secure attachment of the stomach to the peritoneal lined opening in the abdominal wall, and complete occlusion of the peritoneal cavity, are guaranteed. This done, we have an example of the carrying out in its integrity of one of the fundamental rules of practice in the operation of ovariotomy as regards the peritoneum—surface to surface, not edge to edge merely,—and it is a fact not to be overlooked that in gastrostomy the result of the operation seems to depend upon it; the rule being that the cases in which it has been neglected fail, while those in which it is observed end satisfactorily. Thus the lessons learnt at an early stage of our experience in one operation have been the means of leading directly to the successful performance of the other.

This tracking of Paget's extension of the "domain of peritoneal surgery" has carried us a long way, and perhaps those who have entered upon their career at a late stage of the successive annexations may find it not easy to understand the fascination which the subject has for their precursors, who remember its dawning, who were pioneers in realising possibility, and who now live and are still pressing forward to the ever-receding horizon before us. Far as we have come on the way, and much as we have done, there is more to do and more to gain. If formerly we plumed ourselves on our triumphs over the peritoneum—or rather, as it really was, over our fears of the peritoneum—upon our ovarian, uterine, renal, and splenic victories, and put up trophies of all those organs in our museums, we now see our way to new conquests. In proof of this, it is a satisfaction to refer to a series of cases and papers in some of the very latest English and

Digitized by Google

foreign medical journals, showing how much more frequently than heretofore obstruction of the intestines is now successfully treated by operation, and that excision of the pylorus, and of parts of the intestines, is already a subject of careful experiment. This is directly traceable to ovariotomy, for one of the very earliest cases was my own union of the upper and lower ends after removing about three inches of small intestine invaded by cancer from an ovarian tumour. In Treves's paper on Excision of Intestine, you will see how firmly an operator of to-day is taking his stand on the true principles of abdominal surgery which we have watched emerging from their obscurity. He does not ignore the teachings from experiments upon animals. He supports himself by the nine successful resections of lengths of the intestines of animals made by Madelung. He traces the failures in many operations of the same kind on the human subject to faults in the details, such as want of perfect adaptation and insufficiency of sutures. And he lays down as rules for his own action that he must separate the peritoneum from the other tissues, introduce abundance of sutures after Lembert's method, bringing the two serous surfaces together, and avoiding the mucous membrane with the needle. A recent paper by Reichel informs us that already 121 cases of resection of intestine have been collected, the conclusion being that the two ends of the bowel should *not* be united at the time of the resection, but that an artificial anus should be established. This can be closed by a subsequent operation. You will probably soon see a report of a case, not yet published, where Mr. Jessop of Leeds cured a *fæcal* fistula by separating the injured intestine from the abdominal wall, and uniting the upper and lower parts of the gut by suture. What I said with regard to practice on the dead body before operating on living women afflicted by uterine tumours is equally applicable to the resection of intestine. But here practice on the dead is not sufficient, and if we are not allowed to experiment on living animals in this country, we must either go abroad or practise on men and women. At my request a young surgeon, Mr. Jennings, from whom I hope and expect great things in the future, has recently cut away portions of the intestines of dogs, uniting the upper and lower parts so as to maintain the continuity of the canal. Some of the preparations may be seen in our College Museum, and they strongly confirm the conclusion that success depends upon complete union of the apposed serous surfaces.

If I were reviewing modern surgery in general, and not limiting myself to the influence upon it of the revival of ovariotomy, I should speak hopefully of pulmonary surgery, of the draining of cavities in the lung, of incising gangrenous lung, of resection of portions of ribs to obtain contraction and closure of the pleural cavity, and of excision of parts of the lungs, or of an entire lung, even of the surgical treatment of purulent pericarditis. But these are subjects to which I can barely allude as proofs that we do not yet know how far we may go with rational surgery, or what may be in store hereafter for surgical enterprise.

But while we modern surgeons congratulate our science on its liberation from the trammels of tradition, upon its working in an atmosphere cleared of the mist of superstition, upon the changing of its mode of action from a blind grappling with the phantom entities of disease to a study and manipulation of over-nourished or degenerating tissues, upon its having laws which can be understood, and rules of practice which can be followed, we ought not to overlook one fact, which perhaps is more evident to outsiders than to ourselves, standing as we do in the dust and turmoil of the arena of our work. I mean that that work, good and useful as it is, has too much the character of what is technically called "salvaging," is too much in correlation with what is done by the lifeboat service. Is it there that we ought to stop? I know that we are gradually drawing on beyond that point, and that our investigations are turning in the direction of sources, causes, means of prevention, and outlets for avoidance. But before we can reach the same level of achievement in preventive medicine that we have arrived at in operative surgery, before we can arrest the formation of ovarian cysts instead of excising them, we must know and understand what we have to deal with; we must master the problems presented to us by the erratic developments and mortal decadences of the tissues and organs which we are now content to clear away. And we ought to have the means of accomplishing this task on a scale commensurate with the importance of the subject of pathology, the professional desire for original research, and the dignity of the College of which we are members.

Most of the University cities on the Continent have made provision for this necessity, with a liberality and such a profusion of accommodation that the prosecutors of these studies are there at a great advantage. I have visited some of these establishments, and have been able to make comparisons which cause me to regret that so little of the like kind has been done here, and that we have been content to leave a matter which really touches the honour of the profession, and is of national concern, to almost unaided personal zeal and efforts. In England the jesting phrase that "science does not pay" is so common that we scarcely feel the reproach. The history of medical science gives us many instances of unfairly remunerated men (W. Farr, for example), and of the appropriation of the profits of their applied work, and it would be well if the authorities of our profession took the lead in forming an organisation which should aid the modest labourers of its foundations, protect their interests, and reward their industry. I have long desired to see this done by our College, and the munificent bequest of Erasmus Wilson, a man who estimated the value of money by the good that it could be made to do, now puts it in the power of the College of Surgeons to outrival all other corporations, by setting up round the nucleus which Hunter left the most elaborate combination of all the means and appliances for physiological and pathological research, by concentrating the intellectual power which now runs to waste or is diverted to personal interests, and by guiding and directing all that can be done to the advancement of the purely scientific progress of medicine and science.

Last winter I was away from London for about six weeks. While staying at Würzburg and Munich, I could note in the most recently erected pathological laboratories how far our German brethren are in advance of anything which I, at least, have seen in this country. At Rome again, and at Naples, I was both pleased and surprised to find how much our Italian brethren were doing. And during the meeting of the Medical Congress at Copenhagen, I was shown arrangements for the study and cultivation of micro-organisms quite as complete as those which many of you may have inspected at the temporary rooms at the Health Exhibition in London, under the able and instructive guidance of Mr. Watson Cheyne. Now, one may fairly ask why provision cannot be made to ensure the continuance of this work, and its extension, in a better and permanent abode? Something of the kind I hope to see in Lincoln's-inn-fields. I concur completely in the project to make such additions to our noble building as our Council have long felt to be an absolute necessity, and for which they have already considered plans prepared by the eminent architect Mr. Waterhouse. These constructions are intended to furnish better and more convenient arrangements for the examinations for our diplomas, to guarantee the uninterrupted use of the library, and to give us further facilities for the promulgation of the higher truths of surgical science. Unquestionably this will be in some degree a credit to our College and to British surgery. But I hope I shall not be misunderstood. I have no wish whatever to add to the duties of our College as a teaching institution. We are an examining body, acting for the protection of the public by testing the success of the teaching in the schools and hospitals, and vouching for the competence of our candidates for their calling, after proving to us that they have gone through the course of study we prescribe and possess the average skill and knowledge necessary to meet all the usual demands of practice. Perhaps, hereafter, we may take the higher position of sitting simply as a court of judgment upon the qualifications of those who present themselves for our diploma, irrespective of the mode and time and place in which their knowledge has been acquired, putting aside all interference with the routine and details of the course of study.

But I aspire to something more than success in securing the requisite skill in practical surgery in those who dispense themselves among the people as practitioners under our warrant and authority. I trust that we may go further, and, no longer trammelled by State interference and sensational clamour, that we may accomplish that which such men as are on our Council would probably have done long ago, had it not been for the restrictions placed upon them by financial considerations. Now the funds at their command give ample means for the carrying out of any schemes which the most enthusiastic devotee of original research could, in

Digitized by Google

his most sanguine dreams, imagine. My ambition is that we should not merely be the source of honour to students, and the directors and approvers of schools and teachers, but that we should become the centre of medical research, the mainspring of all the developments of medical science. And now that we can do it, why should we not do it? Why should we not have buildings and accessories, imposing in their grandeur and adequate in their accommodation; laboratories, complete in their fittings, instruments, and materials, rooms for conferences, and proper places for the storing of records and results? Why should not our Fellows and Members who are moved with the desire to advance medicine and surgery by inquiry and experiment be presented with as great facilities as are to be found in any continental city or university, such as are so profitably enjoyed by Pasteur, Ranvier, Brown-Séquard, and their colleagues and assistants, advantages hitherto unapproached on this side of the Channel, but which our Transatlantic brethren are not slow to emulate? I feel that to support the honour of our profession, to fulfil our duties as the representatives of surgical science, justly to carry out the intentions of our late president and benefactor, we ought to be magnificent in architectural and constructive outlay, active in personal work, and liberal in the encouragement and help we proffer to those who come to make use of the opportunities which our College will give, and promote the object for which we are all so deeply concerned and so heavily responsible.

I am encouraged to augur the completion of such a scheme as this for rendering original investigation in the future infinitely more easy, precise, and valuable than the surgeons of the past ever hoped for, and to believe in the accomplishment of its designs, when I think that the will of such meetings as this must be obeyed, and feel the conviction that the men of Birmingham will be among the first to avail themselves of it.

I have spoken to you of the past and the present. The future is in your hands; and I appeal to you as men typical of the thought and action of the profession, actuated by the highest moral sentiments, seeking and mutually guarding your honour as a body—chasing out, with instinctive repugnance, that which, ignominious in principle or practice, has accidentally intruded itself among you, and conscious that—by assuming the highest functions of your calling, in the investigation of national interests, in the promotion of public good by giving counsel to princes and legislators, by such a devotion of your energies, by such a sacrifice of personal consideration as is involved in bettering the condition of the people, in shielding them from disease, and in the prolongation of their healthy lives—you will add lustre and dignity to the private confidence, gratitude, and sympathy which the profession has already gained by its power over actual suffering and sickness, and by the skill, conscientious vigilance, and humane tenderness with which you make that power manifest. "I speak as unto wise men, judge ye what I say."

ON THE

NERVOUS OR MUSCULAR ORIGIN OF CERTAIN SPASTIC CONDITIONS OF THE VOLUNTARY MUSCLES.

By SYDNEY RINGER, M.D.,
PROFESSOR OF MEDICINE AT UNIVERSITY COLLEGE, LONDON,
AND
HARRINGTON SAINSBURY, M.D., M.R.C.P.,
ASSISTANT PHYSICIAN TO THE ROYAL FREE HOSPITAL.

(*Concluded from p. 816.*)

THIS peculiar form of rigidity, then, we have observed as one effect of sodium phosphate; as another effect we have recorded fibrillary contractions. What is the nature of these effects? Are they peripheral or central? To answer this question, the hind-limb of a frog, which, by hypodermic injections, had been first brought under the influence of sodium phosphate, was severed from the body, and then the sciatic nerve was faradised momentarily. The result was rigid extension, *which extension persisted some seconds or sometimes some minutes after the discontinuance of the stimulus.*[1] This extension was demonstrable by holding the leg vertically with the foot uppermost, the extension being maintained against the force of gravity for the period mentioned, after which the leg would slowly subside. On performing this same experiment with the muscles of an unpoisoned frog, the contrast was very marked in the sudden collapse of the limb after cessation of the stimulus. In addition to this spastic condition, marked fibrillary action was observed in the poisoned muscles of the severed limb on faradising the sciatic nerve. Clearly, then, the effect is peripheral, not central.

Before analysing further this peripheral effect we may ask, Are we dealing with manifestations purely toxic, or may we observe in unpoisoned muscle anything of a similar character? The answer is that in unpoisoned muscle we may observe both the spastic state and the fibrillation. But observe the requisites: to bring out the spastic state the faradisation must be both *powerful and prolonged*—i.e., *relatively*,—and even then it will be not nearly so persistent as that induced in the poisoned muscles. In like manner, to produce the fibrillary twitchings in unpoisoned muscle, the induction shock must be *powerful*. We observe, therefore, that the effects brought out by the sodium phosphate are not new in kind, but only very much exaggerated in degree. These several points are very strikingly illustrated by means of myographic tracings, but for these reference must be made to the before-mentioned paper in the *British Medical Journal*.

During these investigations certain other facts came out. Thus, it was found that *cold* favoured the production of the spastic state; *further, that repetition of the excitation caused both the spastic contractions and the fibrillary contractions to diminish*; they would, so to speak, wear off.

To proceed with the analysis. The effect we have seen is peripheral. But this includes both nervous and muscular elements; which are the ones concerned here? To answer this, hypodermic injections of sodium phosphate[2] were practised as usual; but, in addition, curare was also injected. The limb was then severed and the sciatic faradised; this yielding no contraction, it was concluded that the motor nerve fibres were paralysed. With such curarised limb a myographic tracing from the gastrocnemius muscle was taken, and it was found that, though fibrillation could still be brought out by the strongest induction shocks, it was greatly diminished, but not so for the prolongation of relaxation; this was even more marked for the curarised than for the non-curarised muscle. This result is extremely well seen in Fig. 4 of the tracings.[3] Observe, then, that with the elimination of the nerve element fibrillary contractions have been much lessened, but the tonic spasm has, if anything, been augmented.

Admitting the efficiency of curare to eliminate the nervous element, the conclusion is inevitable that the tonic spasm is of muscular origin. Nor is this conclusion surprising, for to muscular tissue we unhesitatingly attribute the quality of contractility, but to nervous tissue the quality of conveying the necessary stimulus to call this contractility into action. If now we survey the animal kingdom we note great variation in the mode in which contractility is manifested—i.e., as to rapidity of contraction; and it is most probable that a continuous scale could be established which, according to Marey's statements, would place at the beginning the cross-striped muscles of insects with extreme rapidity of contraction; on this would follow in order the striped skeletal muscles of birds, fishes, mammals, frogs, lowest among striped muscles being those of the tortoise and of the hibernating marmot; then the muscles of the heart would follow, these occupying a mid-way position between striped and unstriped muscular fibre; finally would come plain muscular fibre, whose contraction curve is, so to speak, macroscopic.[4] In addition to this scale we meet with some curious instances of two kinds of striped muscles in the same animal. Thus, in the rabbit we have, as before mentioned, slow and rapidly contracting muscles, these corresponding to the red and the white muscles respectively. But this very slow contraction which we here record may be otherwise described as of the nature of tonic spasm, and accordingly we witness tonic spasm as a normal manifestation in the scale of animal life, and this manifestation we admit to be of muscular origin. Hence analogy comes to the aid of direct experiment, and favours the view that the tonic spasm of drug action is muscular in its nature. But

[1] Loc. cit.

[2] Or sodium carbonate; this salt appears, if anything, more active than the sodium phosphate.

[3] Loc. cit.

[4] Hermann: Lehrb. de Physiologie, Bd. i., p. 38, quotation nearly verbatim.

Digitized by Google

we have seen that the tonic spasm of drug action presents the most striking similarity to the tonic spasm of Thomsen's disease. The inference is immediate, both on the grounds of analogy and experiment, that in this disease also the spastic state is muscular in its nature.

There yet remains for consideration the nature of the change, assuming it to be muscular. Is it to be classed under the heading *morbid*, or under that of *developmental error*? The distinction is an important one. A condition which is *morbid* implies a definite tendency away from the normal, and the divergence once started is a gradually increasing one. Disease implies movement. *Developmental error*, on the other hand, involves no such tendency away from the normal; it is compatible with rest, the degree of divergence from the normal remains a constant quantity. The distinction between the two may also be seen in the relation of the part at fault to the rest of the organism. The diseased structure reacts far more powerfully on the organism generally; it necessitates more or less deviation from the normal in the other tissues of the body; in fact, local disease always signifies to some extent general disease. This can scarcely be said to be the case for developmental error; there is admittedly a flaw in some part of the organism and admittedly a flaw in the working of the organism, in part and as a whole. This must arise from faulty construction, but it can hardly be maintained that the tissues generally take on an unhealthy action in consequence of the local structural error, rather the reverse, their tendency is to adapt themselves to the abnormal state, to compensate for it. It is clear, therefore, that the distinction is an essential one to establish.

To us it appears that the reading of the facts at present is somewhat difficult; for it is undoubted that many of the characteristics of Thomsen's disease are those of a developmental error. Thus, for the most part, the disease appears to be congenital; it shows no definite tendency either to increase or decrease; there is no evidence of general failure either subjectively (to the patient) or objectively (to the physician); the processes of assimilation and of elimination are well performed. Nor if the investigation is made more detailed can any evidence of disease, as we are familiar with it, be detected either in the structures actually at fault, or in those closely associated in function—as, for instance, the nervous structures. (The latter investigation included examination electrically and by means of the microscope.) In other words, search the organism through and in no one part can we find definite evidence of disease; for even in the muscles the peculiarity we note is not associated with evidence, electrical or microscopic, of disease. However, in spite of all this, what are we to do with the fact that the muscular rigidity wears off with repetition of the act of contraction? How, on the view that the muscles of our patient have been arrested at an early stage of development, are we to explain this phenomenon? The evolution would indeed be a rapid one, which in the course of a few contractions would have completed the task of differentiation, and have transformed the slowly acting muscle into a rapidly acting one; not to mention the fact that each such process is followed by a relapse of the muscle to its former state during an interval of rest. This to us appears a serious objection to Bernhardt's view. But even more serious is the fact that we can by means of drugs, sodium phosphate, sodium, bicarbonate, &c., actually establish a condition the facsimile almost of Thomsen's disease, for here we noted not only muscular rigidity in association with contractions voluntarily or artificially excited, but we saw that this stiffness wore off with repetition of the contractions, voluntarily or artificially excited. Other resemblances there were also, these we need not repeat; but the point on which we must lay stress is that this artificial Thomsen's disease is pathological. In the picture of the sodium phosphate rigidity we had to record fibrillary contractions of the muscles. These are not present in Thomsen's disease,[5] but by means of curare it was possible to eliminate nearly completely this fibrillation; hence we must consider the rigidity as independent of this muscular quivering, which would appear to be a nervous effect.[6]

Thus much in respect of an affection in which muscular rigidity appears unassociated with nervous lesions; but rigidity is also found in connexion with nerve-centre lesions; how are we to regard this rigidity? We cannot help thinking that we must regard this still as a muscle effect, and as a result of a change in the muscular fibre; this change may be simultaneous with, or may be consequent on, the nerve-centre change, but that the twofold change is present appears to us most probable. If it be said none will doubt that the spastic state is a muscular effect, since to muscle alone belongs the quality of contractility, it may be replied, clearly not; but many may doubt that a muscular textural alteration is present, and this indeed is the view we find Seppilli[7] advancing, according to whom Thomsen's disease consists in a heightened muscle tonus, *the result of an increased excitability of the innervation centres in the cord*. On this, however, we cannot further dwell now, for it is in the foregoing—namely, in the reading of the experimental facts, and also of the facts concerning Thomsen's disease, both of which show rigidity apart from nerve-centre lesion—that we think the argument for the myopathic theory of muscular rigidity in general is to be found. As a last word of caution, we must insist that the muscular rigidity of which we here speak is quite different from that rigidity to which we give the name tetanus. In this latter we have the muscles maintained in a contracted state because a continuous inflow of stimuli into the muscle is obtaining; so soon as the inflow stops, so soon does the contraction cease; but here it is precisely with the cessation of the stimulus that the effect comes out—the muscle is thrown into contraction, and then *when you wish to relax it* you cannot.

In conclusion, we may remark that further reference on the literature of the subject may be found in Virchow and Hirsch's *Jahresbericht* for 1884,[8] but the facts there found are almost all included in the previous records we have quoted from, with the exception that two of the cases there recorded by Engel[9] and Schönfeld[10] gave a history of sudden onset. These will class themselves along with the one recorded by Seeligmüller, and are on the side of the pathological view of the disease.

CHOLERA.

BY MAX VON PETTENKOFER, M.D.,
OF MUNICH.

(*Continued from page 819.*)

HAVING now discussed the relations in time and space which predispose to cholera, I shall pass on to consider those relations in regard to the freedom from cholera which they may enjoin. Places which enjoy an immunity from cholera are more numerous than was formerly supposed, but have been less studied from a point of view of epidemiology, just as relations in time have been but little investigated. The eye of the investigator has only fixed itself on the places where, and at the time when, cholera has reigned. We ought likewise to investigate the matter when and where cholera does not exist. Ordinarily a physician only bestirs himself when he is called to see a case. It has, however, not been so with me. Impressed with these notions, I went in 1868 to the place in Southern France which had enjoyed the greatest and most renowned immunity from cholera. Through the kindness of M. Fauvel I was introduced to M. Luuyt of Lyons. Although Lyons was in frequent communication with Marseilles and Paris when epidemics of cholera raged, yet the disease never showed itself in an epidemic form at Lyons. In 1849, for instance, Lyons was besieged, conquered, and invested by troops suffering from cholera. Then the town escaped, whilst the soldiers suffered severely. This immunity was certainly not due to greater cleanliness of that quarter of the town known as Croix Rousse; nor was it due to the social misery or to the wants of the working classes; neither had the drainage or water-supply, which prior to 1858 was as bad as it could be, anything to do in the matter. So that the immunity was probably the result of natural conditions. The Lyonese had often congratulated themselves on this excellent gift of nature, but it is probable that the constant movement of air

[5] One of Seeligmüller's patients was an exception to this statement.
[6] This observation is suggestive of the view that the fibrillary contractions so frequently witnessed in certain nervous diseases—progressive muscular atrophy, labio-glosso-laryngeal palsy—are a nervous and not a muscular fibre effect.

which the combined flow of two great rivers (the Rhône and the Saône) originate is the cause of the immunity, although the mistral (*Mistralstürme*) which scours Languedoc and Marseilles had never been able to drive the cholera away. The situation of Lyons is far different; the bed of the two rivers is composed of compact granite, which on the right bank of the Rhône and on both banks of the Saône rises high, being in places coated with lias, molasse, and thick mud strata. On the heights lie the parts of the town called Croix Rousse, Fourvière, and St. Juste; other quarters lie low—Perroche on a tongue of land between the two rivers, Lyon Vaise on the right bank of the Saône, and Brotteaux and Guillotière on the alluvial soil of the left bank of the Rhône. The lower parts of Lyons are frequently and deeply flooded over, and yet the cholera never comes!

Just as the disposition to cholera in time and place may be due to two causes, so may the immunity from cholera be dependent either on the physical nature of the soil, as is the case in parts of Traunstein and Kienberg, or on the condition of the soil as regards moisture, as happened in the low-lying parts of Munich during the summer epidemic of 1873, or at Augsburg during the summer and winter of 1873, or at Munich in 1866. Such a degree of wetness as prevailed on those occasions may be a constant condition in some places, to this latter group the low-lying districts of Lyons belong. Indeed, both factors are at work in Lyons. In the high-lying parts the granite comes to the surface in many parts, and so a very efficient and natural drainage is secured. These districts may always be said to be free from cholera. The soil of the low-lying parts, situate on the banks of the Rhône, Brotteaux, Guillotière, and Perroche, has always a certain degree of humidity, which cholera when imported has to encounter. This moisture of the soil of parts of Lyons is dependent not only on rain, but also on the river Rhône. The impermeable bottom of its bed is of solid granite, to which fact I could bear personal testimony. This stratum of granite stretches from the left bank of the Rhône far inwards, so that Lyons is built upon it; all the springs lie below the level of the surface of the waters of the Rhône, and so rise and fall with the river. In Paris, in Munich, and in Berlin the conditions are otherwise. Here the level of the subsoil water is above that of the level of the waters of the Seine, Isar, and Spree respectively; this relation is the most general, so that Lyons is exceptional. In Lyons it may be said that a part of the Rhône runs subterraneously, so that the soil receives water from the river; whereas in Paris, Munich, and Berlin the direction of the water is constantly from the soil to the river. When the water rises in the beds of the Seine, Isar, and Spree there is no penetration of the water into the porous soil, but rather a damming and stagnation in the discharge of the subsoil water. The granite of the Rhône, chiefly composed of large blocks of quartz, contains also much fine sand, which is able to suck up water to a considerable height in its capillary spaces, possibly as high as the zone of evaporation. I investigated the hardness and moisture of this quartz by actual digging. This part of Lyons is only at times free from cholera, and would be susceptible of an epidemic were some of its water taken away. That Lyons may be fatally visited was shown in the year of cholera, 1854. As I was studying the conditions of cholera in Lyons, I found that in 1854 no less than 500 deaths occurred from the disease; whilst at other times the town escaped with a dozen deaths. It also transpired that nearly three-fourths of the deaths happened in Guillotière, and I must say, therefore, that in the year 1854 at least a part of Lyons suffered from an epidemic of cholera. The Lyonese were not pleased with this assertion, because they had always boasted of their immunity from cholera; they replied, "What are 500 deaths out of a population of 400,000 It is absurd to call that an epidemic." Of course it would not be right to speak of an epidemic of all Lyons, but most assuredly there existed an epidemic in a part of it. The higher lying districts had enjoyed their usual immunity in 1854. In the times of cholera which followed 1854 Lyons preserved its freedom. In what respect did 1854 differ from all other years? In nothing but in the fact of its greater dryness. I availed myself of the observations of the meteorological station, and found that in this year the amount of evaporation was greater than the rainfall. Observations on the subsoil water were not to be obtained, but there was the register of the condition of Rhône dating as far back as 1828. From 1826 to 1854 there was no lower register so lasting as that of the last year. These facts were sufficient to lead me to understand how the lower lying parts of Lyons could be brought into a condition susceptible of an epidemic of cholera by the partial or total removal of the influence of the Rhône.

That too much as well as too little water in the soil is unfavourable to cholera is vouched for by a large mass of facts. As I watched the cholera in Bavaria during 1854 I was surprised to find that the marshy districts, where, as a rule, the poorest dwelt, were exempt from epidemics. The great Donau bog, which lies between Neuburg and Ingolstadt, was surrounded by the epidemic, but the disease did not enter the villages on the fen. On the Freisinger moors an epidemic occurred at Halbergmoos. On going thither the affected houses were found to stand on a tongue of land composed of quartz, which tongue reached inwards on the moor. Reinhard had proved the same thing for Saxony. The northern part of Saxony, which lies on the Spree, is a highly malarious district. For the eleventh time that cholera visited Saxony it shunned this region of fever. I will not say that cholera cannot be epidemic on a fen, but I do believe that when such an occurrence takes place we ought to ask ourselves what relation it may have with the state of moisture of the soil. The theory of the soil and subsoil water requires that a knowledge should be obtained of what takes place in and over the soil on the outbreak, and on the cessation of cholera. It requires, as Port has said, a continuous record of facts. That cholera should very seldom be met with in the neighbourhood of and on mountains is also in harmony with the disposition of cholera in respect of time; so that as the frequency of cholera in these regions diminishes the rainfall increases; the weather and cholera are equally capricious. Towns amongst mountains which are refuges for the fugitives from cholera are but seldom situate on a soil which in and of itself would exclude cholera. Salzburg and Innsbrück have, for example, never yet been visited by cholera. Further, in 1866, these towns escaped although a considerable influx took place from the seat of war where cholera raged. Salzburg, but still more Innsbrück, stands on the alluvial soil of the Salzbach and the Inn, as Munich stands on the Isar; but the first-named towns have about 50 per cent. more rainfall than Munich. I can only imagine that the necessary degree of dryness for the development of cholera would be attained but very rarely in Salzburg and Innsbrück, just as occurred partially at Lyons in 1854, and in June, 1859, at Bombay, where cholera prevailed during the monsoons, which, as a rule, drives the cholera away.

The disposition of cholera in regard to time is also evidenced in the fact that cholera is so different in one and the same place at different times, or at like times in one and the same place, if different parts of the place have different kinds of soil. For instance, in Munich the houses situate on the clay ridge of the suburb of Haidhausen are never affected, but this exemption is certainly not due to the supposed prevention which clay soil in and of itself exerts against the development of the germs of cholera, but because the behaviour of rain on clay and rocky soils is very different if the rain be equally distributed over the two kinds of soil. When the rocky soil at Munich was ready for cholera the clay soil was not.

I shall now leave the arguments for the localists, and pass on to consider the circumstances which are favourable to the views of the contagionists.

That an epidemic of cholera does not permanently last in one place, but after a longer or shorter time ceases, is explained by the contagionists as due to the saturation of the population, whereby each individual acquires a protective influence against cholera similar to that acquired after vaccination as against small-pox and other like instances. This hypothesis does not explain why an epidemic is sometimes rapid and sometimes slow in its course, why it is sometimes vast in its ravages and at other times slight in its effects, whilst the condition of mankind remains practically the same. With as much reason might the localists assert that the germs of cholera find at different times the local conditions to be favourable or unfavourable with the natural consequences of growth or death. Now, in districts where cholera is endemic, as in the soil of Lower Bengal, it is easy to suppose that at one time the conditions for the multiplication of the germs are present, whilst at another time the opposite state prevails. The dormant condition of the germs must, for a limited time, frequently exist in districts outside India. This supposition will not explain the occurrence in the low-lying parts of Munich of the severe winter epidemic of 1873–74, after the summer epidemic in the higher parts of the town had ceased.

Digitized by Google

It follows that we must suppose that the germs which give rise to an epidemic may arrive at a place and there exist for some time (in Munich for three months) without showing any manifestations. And that, indeed, the germs may die before the necessary local conditions for their growth and multiplication are present. So that one might seek in vain to trace the connexion between cases of cholera coming from without and the first cases of illness occurring in a place, as happened in 1883 at Damietta in Egypt, and in 1884 at Toulon in France. The germs may have arrived six months before without finding the necessary material for their growth, and consequently may die out before giving any signs of their existence.

How long the germs of cholera may remain latent in a place we have no evidence to show. There are cases in which we might say that a whole year elapses, but instead of that I think it can be shown that in Europe the germs die out. Since cholera has lasted for many years in Russia, some epidemiologists have supposed that in Russia in the North, just as in Lower Bengal in the South, cholera is endemic. The history of cholera, however, in two islands of the Mediterranean, Malta and Gozo, supplies an example to the effect that the germs of cholera may die out in the space of a few years, and that the germs must be again imported before fresh cases of Asiatic cholera can appear. The islands of Malta and Gozo lie near one another and are by nature so similar that it might be imagined that a single homogeneous rock had been split into two parts, a greater and a smaller, which lie as near together as possible in the water without touching one another. It is thus that the two islands project from the sea. Each has the same kind of soil, enjoys the same winds, the same sunshine and rain, the same population of Arabic origin, with like manners, customs, and daily intercourse. Vegetables, fruit, and cattle for slaughter pass daily from Gozo to Malta. The two islands differ in that Gozo has no direct intercourse with the world at large, whilst Malta is famous for its natural harbour. Both islands have experienced epidemics of cholera, but Malta was always invaded some weeks before Gozo. Finally both islands show themselves equally susceptible to cholera. In 1865 in Malta 12 per 1000 of the population, and in Gozo 10 per 1000, died of cholera. The first case of cholera occurred in 1837 on May 26th in Malta, and on July 5th in Gozo; in 1850 it was June 9th and Aug. 28th respectively. In 1854 and 1856, during the Crimean War, cases of cholera appeared in Malta and Gozo, but not in an epidemic form; nevertheless, sporadic cases first showed themselves in Malta. In the epidemic of 1865 the first case occurred in Malta on June 28th, and in Gozo on July 21st. This interval of time between Malta and Gozo makes me suspicious of the current doctrine that cholera can occur in places two days after the arrival of the infecting cases; for it has not been proved that cases might have arrived still earlier. The instance of Malta and Gozo clearly proves that cholera may have no long duration, that it is not autochthonic, that it is not brought by the wind, but that for its passage intercourse is necessary.

The facts of the influence of locality the contagionists cannot deny; indeed, they accept the facts but explain them in another way. Attempts are made to show by the localists and contagionists, how the germs of cholera spread by means of human intercourse may act in harmony with the conditions of soil and subsoil water. This is unfortunately still the darkest chapter in the book, and will probably remain so; but it is not darker than the explanation of the nature of another infectious disease which is equally dependent on conditions of soil and water—namely, malarial fever. We are firmly convinced of its telluric and climatic origin, and yet a study of von Hirsch's "Handbook on Historio-geographical Pathology" shows how little we know. Whether the infective material gets to man from the air, or water, or food, or the sting of a gnat, and so forth, we know not; and if we examine the tables showing the appearance of ague in the different months of the year in Leipzig, Vienna, &c., we come to see that the tables are not so very different from those drawn up by Brauser on cholera. In malarial fevers it is doubted whether infection is conveyed by the drinking water, whereas contagionists believe that cholera is propagated through this source. The drinking water theory played a great part in the causation of epidemics in the Middle Ages; it was believed that wicked men, either Jews or Christians, had poisoned the springs from which death was drunk. For good health, pure water is as necessary as pure air, good food, comfortable quarters, and so forth. I myself am an enthusiast in the matter of drinking water, but not from fear of cholera or typhoid fever, but simply from a pure love for the good. For me water is not only a necessary article of food, but a real pleasure, which I prefer, and believe, to be more healthful than good wine or good beer. When water fails, man may suffer not only from cholera, but from all possible diseases. In places where cholera prevails the water may always be indicted, for the water-supply is always a part of the locality, and the doctrine will frequently hold good, because the part may be mistaken for the whole. Where the influence of the water is held up to the exclusion of all other local factors error is liable to creep in. In England, where the drinking water theory is fully believed in, two like influences, in which every other local factor was excluded, were observed in the cholera epidemic of 1854. In one case, in a street in London which was supplied by two water companies, the Lambeth with pure water, and the Vauxhall with impure water, it was found that the cholera was practically limited to the houses supplied by the Vauxhall Company. I was so much impressed by this fact that I endeavoured to see whether the epidemic of 1854 in Munich could not be explained on a similar hypothesis. But my researches led me to a negative result. Without doubting the facts observed in London, I am of opinion that the impure water of the Vauxhall Company did not spread the germs of cholera, for the propagation of cholera was not effected by this means in Munich, but that the water increased either the personal predisposition to cholera or perhaps the local predisposition, since the water would be employed in the houses and about the soil. Later on, in 1866, Letheby doubted the accuracy of the drinking water theory, and proved that there had been considerable confusion; so that a house which was registered on the Lambeth Company really drew its water-supply from the main of the Vauxhall Company, and *vice versâ*. The cholera epidemic of 1866 was essentially limited to East London. The East London Water Company supplied this district with water filtered from the river Lea. Letheby brought forward a series of facts to prove that we might with equal justice accuse the East London Gas Company, since the first case of cholera broke out at the gas factory. A second instance in London was that with which the name of Dr. Snow is associated. Golden-square, a part of London with very deficient drainage, was the scene of a severe epidemic of cholera in 1854. The epidemic concentrated itself in Broad-street. There must have been some reason for this, and the reason must be discovered. Where Golden-square and Broad-street stood was formerly a place of burial for individuals dead of the plague. This pest-blast of a former century could walk rom its grave in A.D. 1854 like the Ghost in Hamlet. But a narrower inspection proved that the old pest field and the new cholera field were not exactly coextensive. Now, however, another fact was brought to light, which led to the substitution of the drinking water as the cause. In the middle of Broad-street there stood a pump of which the water was much esteemed on account of its freshness. At the end of August, whilst the cholera was raging, it was found out that many sufferers had drunk of the pump water, but the fact was not sufficiently decisive, and so a pathological experiment was required. In Broad-street there was a percussion cap factory belonging to Mr. Eley. The persons of this establishment suffered from cholera, and many of them died. Mr. Eley remained well, but he did not live at the factory, though he went there daily and returned home to Hampstead after business, and there lived with his mother and a niece. His mother, who formerly lived in Broad-street, had a great liking for the water of the pump-well, which was shown in the fact that her son daily took home the water for his mother and niece. In Hampstead there had been no case of cholera until the mother and daughter fell ill and died of cholera without having any other communication with Broad-street than through the means mentioned. What more is wanted? Who can doubt any longer? An experiment on two human beings with a disease which animals are not susceptible to! A sad privilege! Never before had facts received a more frivolous interpretation. Suppose, for a moment, that Mr. Eley had gone to and from Hampstead to Broad-street without having taken the water to his mother and niece; and, further, that they had become ill of the cholera without having drunk the pump water, would it have been imagined that the cholera had been carried by the son, who remained in good health? The contagionists would probably reply that Mr. Eley may

Digitized by Google

have had the cholera in a mild form. The localists would say that a poison locally originated might be passed on by healthy people without giving signs of illness in them. In 1854, for example, a young lawyer went from Munich to Darmstadt, where his father resided. Up to that time the father had never lived out of Darmstadt, and Darmstadt was as free from cholera as Hampstead, and the distance from Munich was much greater than Hampstead from Broad-street. The lawyer was as well in health as Mr. Eley had been, but the lawyer's father fell ill and died of cholera. There was no other factor in the case than the return of the son from Munich. Darmstadt enjoyed an immunity from cholera as great as that of Lyons, Versailles, Stuttgardt, and many other large cities. In 1854 a workman went home from the Exhibition of Munich to Darmstadt, where he fell ill and died of cholera without the disease being spread to any other house, and no means for disinfection or isolation had been adopted. In 1866 Prussian troops were quartered in Darmstadt, and brought the cholera with them. About thirty of the soldiers became ill with cholera, and many of them succumbed; again, none of the inhabitants of Darmstadt had the disease. It must be admitted that Mrs. Eley might have been infected through the intercommunication of her son, just as the lawyer's father had been without the intervention of drinking water. The argument in favour of the drinking water theory rests on the fact that the cholera ceased when the supply of water was cut off; but no notice was taken of the great majority of cases in which the water springs were not closed and the supply of water not cut off, and yet the epidemics came to an end. Again, in Broad-street the pump handle was not taken off till Sept. 8th. Now, an examination of the facts will show that the cholera was already subsiding. In Broad-street, on August 31st, there were 31 cases of cholera; on Sept. 1st, 131 cases; on the 2nd, 125; on the 3rd, 58; on the 4th, 52; on the 5th, 26; on the 6th, 28; on the 7th, 22; and on the 8th, 14. Just as occurs in India and elsewhere, a violent epidemic generally subsides rapidly.

(To be continued.)

DILATATION OF THE CALIBRE OF SMALL ARTERIES.

IS IT A FACT IN NATURE, DISCLOSED BY "EXPERIMENTAL RESEARCH," THAT DILATATION OF THE CALIBRE OF SMALL ARTERIES IS *PRIMARY* AND OWING TO AN *ACTIVE* EXPANSION OF THEIR WALLS UNDER THE INFLUENCE OF SPECIAL VASO-DILATOR NERVES?

An Inquiry addressed to Physiological Authors, Professors, and Occasional Orators.

By T. WHARTON JONES, F.R.C.S., F.R.S., &c.

In the web of the frog's foot or bat's wing spread out under the microscope, we may sometimes see small arteries with their calibre constricted to such a degree that the stream of blood in them is for the time wholly interrupted. When, in such a case, the blood begins to flow in them again, this is observed to take place by a corpuscle or two, at first, and then more and more, forcing, under the influence of *vis a tergo*, a passage, until the calibre of the vessel becomes enlarged by distension with a full and rapid stream of blood. In this case the capillaries and venous radicles are also dilated by distension, with the increased quantity of blood thereby delivered into them. They do not of themselves become actively dilated. This dilatation of small constricted arteries is evidently owing to the distension of their calibre with blood, when, in consequence of relaxation of the circular muscular fibres, their walls yield to the distending force from within of the full stream. There is nothing observable in the phenomenon of the re-establishment of the flow of blood, in a constricted artery, to indicate that dilatation of its calibre precedes the entrance of the stream, and is owing to a primary active expansion of its wall. No intrinsic muscular mechanism of the arterial wall is known to exist by the agency of which a primary active dilatation of calibre could be produced. Is it not, therefore, quite unwarranted to assume the existence of vaso-dilator nerves for the government of a *nonentity*? There is not in the small arteries under notice an indication of even anything like the operation of elasticity of wall such as is presented by larger arteries. In the case of the rhythmically contractile veins of the bat's wing, the diastole which succeeds the systole is produced by an elastic recoil, as will be explained in another communication.

The only active mechanism inherent in the walls of the small arteries that can be discovered consists of the circular muscular fibres, by the contraction of which the calibre of these vessels is constricted, and the only vaso-motor nerves indicated by direct experiment are those under the influence of which the said circular muscular fibres contract, and probably nerves exerting an inhibitory influence on the action of these constrictor nerves. Constriction of the calibre of an artery by contraction of its circular muscular fibres, as we can see in the web of the frog's foot or bat's wing under microscopical examination, is propagated for some distance backwards in the direction of the trunk, as well as forwards, whereby the blood is not only arrested in its course, but is actually regurgitated. This phenomenon, with the attendant exsanguine state of the part, we can also see with the naked eye in the case of the large artery of the rabbit's ear, as well as perceive, by the touch, the consequent fall of temperature. Small arteries remain constricted, though their muscular coat has become relaxed, until distended by the full stream of blood entering them under the influence of *vis a tergo*. There is, as above observed, no elastic dilating reaction of the walls of small arteries like that of the walls of a caoutchouc tube, such as is presented by larger arteries. In the undistended state of the small arteries (the lumen remaining passively constricted) their wall is seen under the microscope to retain the thickness which we see it acquire when the muscular coat becomes contracted. This condition of the arterial wall persists, more or less, in the dead state, and has been erroneously described as hypertrophy. I have seen preparations of such exhibited as examples of "arteries with hypertrophied walls." In this case the accompanying constriction of the calibre of the vessel seems not to have been taken into account; for surely an hypertrophied artery ought to present an enlarged calibre as well as a thickened muscular coat.[1]

The fact that the calibre of arteries is constricted by contraction of their walls proved that the circularly disposed fusiform nucleated cell fibres composing their middle coat are muscular; the contractility of the arterial wall having been known before, the demonstration of the existence of fusiform fibres was not the proof of it, as has been illogically asserted; the nucleated cell fibres composing the middle coat of arteries, being unlike common muscular fibres, were not recognised in dissection as muscular until the structure into the composition of which they enter was observed to contract in the living state. Contraction of the muscular walls of the extreme arteries with constriction of their calibre on the one hand, and relaxation of the muscular walls of these arteries with dilatation of their calibre by distension with blood on the other, are facts which constitute the key to an explanation of the emptiness or fulness of the capillaries and venous radicles of a part. The emptiness and fulness of the vessels which we can see with the naked eye in the rabbit's ear alternating at certain intervals, though not rhythmically, are thus explained, as are also the alternating pallor and redness in blushing.

It has been erroneously alleged that by the constriction of the artery of the rabbit's ear, recurring at short intervals, the blood is accelerated in its onward course; whereas it is an easily observable fact that in consequence of the propagation of the constriction of the artery trunkwards, the flow of blood is not only arrested, but is actually squeezed back, so that the ear becomes exsanguine and cold, as before mentioned. And how could it be otherwise, seeing that there are no valves within the artery to prevent regurgitation?

This gross blunder first arose from a mistaken comparison with the phenomenon of rhythmical contraction and dilatation—the systole and diastole—presented by the veins of the bat's wing, which are furnished with valves. By the rhythmical contractions of the veins of the bat's wing, supported by the valves, the onward course of the blood to the

[1] Are not the enlarged communicating arteries, through which the circulation is carried on in a limb when the main artery is obliterated, entitled to the designation of hypertrophied arteries? Communicating arteries, it is here to be remembered, are *not* capillary arteries, as they were designated by the orator on the occasion of the inauguration of Harvey's memorial at Folkestone, in making a claim for John Hunter to be placed, in idea at least, on the pedestal side by side with the hero of the day!

Digitized by Google

heart is promoted; whereas by the occasional tonic contractions of the artery of the rabbit's ear, which endure for a short though an indefinite time, the onward course of the blood is not only arrested, but the stream is made to regurgitate. The ensuing enlargement of the artery by distension of its calibre with blood when its wall relaxes is erroneously assumed to be an active and primary dilatation. This blundering is professed in books and lectures on physiology in a more disgracefully stupid manner even than is here represented. Thus, in one book it is stated that "the rhythmical contractility of vessels *may* appear under two forms: (1) rhythmical contractions which have been observed in the rabbit's ear (?) *or* in a bat's wing; (2) persistent contractions under the influence of the nervous system, which play an important part in the distribution of the blood." Wherein consists that important part is, however, not explained, nor is any reference made to the special effect on the flow of the blood produced by the alleged two forms of *rhythmical contractility of vessels*. In another book, it is said that "small arteries often contract rhythmically," and that "in certain (?) animals veins contract rhythmically." With what effect on the flow of blood is not mentioned, and as little the difference between rhythmical contraction and pulsation. In a third book, rhythmical movements are erroneously alleged to be manifested by the caudal vein of the eel, while no mention is made of the lymphatic heart and the rhythmical propulsion of lymph by it into the vein, though without causing any pulsation of that vessel.

When the walls of the artery of the rabbit's ear relax, we see that the blood, again entering the vessel, dilates its calibre by distension, and flows into the capillaries in full streams. Again, in blushing, arteries, capillaries, and venous radicles are said all to dilate actively, and that the supervening paleness of face is owing to active constriction of these vessels. This, however, betrays an utter misunderstanding of the mechanism of the circulation in the extreme vessels. If, as I have above maintained, there is no provision for an active dilatation of the small arteries, still less is there a provision for an active dilatation of the capillaries and venous radicles. Their dilatation is owing to distension by the increased afflux of blood into them from the relaxed arteries giving passage to fuller streams. As to constriction of capillaries and venous radicles, I never saw capillaries become constricted to closure, and have no doubt that the vessels alleged to have been capillaries becoming constricted to this degree were extreme arterial ramifications, which in the ordinary state of the capillary circulation in the frog present a narrower calibre than the capillaries themselves, as may be seen represented in Plate 4 of my essay on "The State of the Blood and the Bloodvessels," in Guy's Hospital Reports for October, 1850. I long ago pointed out that the small vessels in the mesentery of the frog described by the late Professor Th. Schwann as capillaries with thick muscular walls are, in reality, small arteries opening directly into the side of venous trunks, there being no capillaries in the frog's mesentery nor venous radicles. When vascular fulness becomes diminished in consequence of the walls of the relaxed and distended arteries resuming the ordinary medium degree of contraction and constriction, the capillaries resume their ordinary width by elastic reaction of their walls, but do not close in; whilst the venous radicles become so far constricted by the tonic contraction of their muscular coat, that their calibre is accommodated to the diminished influx of blood.

Notwithstanding that the mechanism of the circulation in the extreme vessels is such as I have here described, experimenters talk indiscriminately about an action of "all the vessels," capillaries and veins as well as arteries. In the first edition of my work on Ophthalmic Medicine and Surgery, published in 1847, as also in the two subsequent editions, I remarked that the increased vascular fulness of the eye, observed by Pourfour Du Petit in 1727 as an effect of his experiment of dividing the sympathetic nerve in the cervical region of a dog, was to be attributed to paralysis of the muscular wall of the arteries of the organ, induced by loss of the nervous influence governing them and to the increased afflux of blood permitted by the arterial relaxation. This point I specially elucidated in my essay in Guy's Hospital Reports for October, 1850, and at the same time retracted an erroneous view I had previously expressed as to the direct effect on the blood produced by the suspension of nervous influence. I there showed by microscopical demonstration that the increased vascularity of the leg and web of a frog, which takes place after section of the trunk of the ischiatic nerve in the thigh, is owing to fuller streams of blood in the small arteries (permitted by the relaxation of their muscular walls, resulting from the section of the ischiatic nerve), and consequently fuller streams in the capillaries and venous radicles. The elucidation of the state of the blood and the bloodvessels on which the phenomena of increased vascular fulness depend, after section of the nerve fibrils in the ischiatic trunk which govern the contractions of the walls of the small arteries, obtained from these experiments on the frog, is of a more exact character than can be gained from section of the nerve fibrils in the ischiatic of the dog, which govern the small arteries of the leg and paw. The reason is that we can examine the frog's web under the microscope, and observe in it the fuller flow of blood to the capillaries and venous radicles from the arteries dilated by distension of their paralytically relaxed walls, whereas it is impossible in the experiment of dividing the ischiatic in dogs to make any microscopical examination of leg and paw in order to ascertain the exact state respectively of the small arteries, the capillary network to which they lead, and the radicles of the veins which arise from that network, together with the state of the blood in the injected parts. The inferences as to the point drawn from the increased temperature are of insufficient validity. What I have here said of the insufficiency of the experiment of dividing the ischiatic in the dog is applicable to the experiment of dividing the cervical sympathetic.

Subsequently to the publication of my essay on the state of the blood and bloodvessels in inflammation in Guy's Hospital Reports for October, 1850, Du Petit's experiment of dividing the sympathetic nerve in the region of the neck in dogs, performed more than a hundred years before, came to be repeated on cats, rabbits, &c., by the late Claude Bernard, Brown-Séquard, and many other physiologists. Whatever light these experiments may have thrown on the centres of the nerves operated on they did not, and could not, add anything to the elucidation of the action of the vessels concerned in the extreme circulation. From his experiments the late Claude Bernard deduced nothing more in regard to the mechanism of the circulation in the extreme vessels than what I had pointed out as deducible from the experiment of Pourfour Du Petit; and certainly nothing so precise and detailed in regard to the mechanism of the circulation in the extreme vessels as that which I had previously shown to be observable in the frog's foot after section of the ischiatic nerve. Notwithstanding this, M. Paul Bert, who is as imperfectly informed on the subject of the mechanism of the circulation in the extreme vessels as his friend Bernard was, has laid claim for him that by the repetition of Du Petit's experiment he has presented the problem of the circulation "under an absolutely new aspect."

By this assertion M. Bert seems to imply that Claude Bernard elucidated the mechanism of the circulation in the extreme vessels in a more complete and correct manner than had been done before. It does not appear, however, wherein such elucidation consists. M. Bert does not seem to have made himself acquainted with the aspect under which the mechanism of the circulation in the extreme vessels is presented in my essay published in 1850, nor with the explanation given by Brown-Séquard as to the cause of the heat—viz., that it is the afflux of blood to the parts, and not the loss of an unknown influence exerted by the sympathetic, as Bernard supposed. Notwithstanding this, I find M. Paul Bert's parable taken up in a late Harveian Oration at the Royal College of Physicians as a standard outcome of "experimental research."

In the experiment of dividing the ischiatic nerve of a frog, the relaxation of the muscular coat of the arteries, on which the dilatation of their calibre by distension with blood depends, appears to be an effect of section of special vaso-constrictors, derived from the sympathetic, bound up in the ischiatic trunk, and not of fibrils derived from the spinal cord. Thus, I showed, in a paper on the State of the Blood and the Bloodvessels in Inflammation, in the Medico-Chirurgical Transactions, vol. xxxv.,[2] that if we lay open the lower part of the vertebral canal of a frog, and remove the roots of the ischiatic nerves with the corresponding portion of the spinal cord, so that all sensation, voluntary motion, and spinal reflex action in the posterior extremities are abolished, the walls of the arteries are, nevertheless,

[2] The paper was given in to the Royal Medical and Chirurgical Society in May, 1858.

Digitized by Google

seen, on examination of the webs under the microscope, to retain their contractility; nay, they appear even more disposed to become contracted so as to keep up greater than ordinary constriction of the calibre of these vessels.

When now the trunk itself of the ischiatic nerve in the thigh—which comprises not only the spinal fibrils, sensitive and motor, the roots of which were with the corresponding portion of the spinal cord destroyed, but also fibrils from the sympathetic nerve in the pelvis as yet uninjured—was divided on one side, the skin of the extremity subjected to this part of the experiment was seen by the naked eye to become redder from general vascular fulness than that of the opposite extremity, and on microscopical examination of the web, the arteries were observed to be relaxed and dilated by distension with full and rapid streams of blood injecting the capillaries and venous radicles. In the web of the opposite extremity, in which the trunk of the ischiatic nerve in the thigh was left uninjured, the arteries were, on the contrary, seen much constricted, some even to closure. This remarkable fact would appear to indicate something like the operation of inhibitory nervous influence having been arrested by the destruction of the spinal roots of the ischiatic nerve and the corresponding portion of the spinal cord whence they originate, leaving the vaso-constrictors derived from the sympathetic in uncontrolled action.

Still holding firmly in view the fact that there is no primary active dilatation of the small arteries, that there is no vaso-dilator organ, and consequently no vaso-dilator nerves to excite an organ which does not exist, we may from this experiment admit inhibitory nerve fibrils in the spinal roots of the ischiatic nerve which control and suspend the action of the vaso-constrictor nerve fibrils derived from the sympathetic, and so permit relaxation of the muscular coat of the small arteries, whereby they are brought into a condition to become dilated by distension with the blood now more freely entering them. In the converse experiment of the late Claude Bernard, nervous inhibition was directly indicated by irritating the chorda tympani. When this nerve was excited by electricity, the walls of the small arteries of the submaxillary gland became relaxed, so that the blood flowed more freely through them into the vein, whence blood issued in larger quantity. This experiment certainly did not prove the existence of vaso-dilator nerves; and, it might be said, not even inhibitory nervous action. The relaxation of the walls of the arteries by the electrical irritation of the chorda tympani may have been merely owing to transient paralysis from over-excitement of the vaso-constrictors. In the web of the frog's foot under the microscope we see as the effect of the application of a drop of some irritating liquid, such as spirit: (1) constriction of the small arteries and impeded flow of blood; and (2) dilatation of the small arteries by distension with blood now flowing in full streams. The constriction in the first instance was owing to primary contraction of the muscular walls of the small arteries from excitement, direct or reflex, of the vaso-constrictor nerves of the spot; whilst the distension with blood in the second instance was permitted by relaxation of the muscular walls, arising, no doubt, from the supervening exhaustion of vaso-constrictors occasioned by the over-excitement.

In whatever way brought about, however, it still remains a fact that relaxation of the muscular coat of small arteries is the condition for dilatation of their calibre by distension with blood. Primary active vaso-dilatation is a mere assumption. The experiments on living animals which have been performed in order to prove the existence of vaso-dilator nerves and a mechanism on which they exert their excito-motor influence are utterly inconclusive, little better than gambling in vivisection with the expectation of eliciting something by chance, and betray on the part of the experimenters a want of fundamental acquaintance with the mechanism of the circulation in the extreme vessels and with the different parts played therein by the small arteries, capillaries, and venous radicles. Thus it is that experiments are sometimes performed on living animals in order to ascertain the special action of nerves without a preliminary acquaintance with the mechanism of the organ, the nervous influence on which constitutes the subject of research; nay, experiments are performed in order to demonstrate the action of supposed nerves of imaginary organs, of which the existence is assumed in order to account for inaccurately observed phenomena. And all this is dignified by the name of "experimental research," while such crucial facts as the directly observable mechanism by which the flow of blood is promoted in the veins of the bat's wing, and the remarkable phenomenon attending the propulsion of lymph from the lymphatic heart in the eel's tail into the caudal vein are unstudied and stupidly misrepresented.

Postscript.—Since this inquiry was written and left my hands, the Harveian Oration at the Royal College of Physicians for this year has been delivered and printed. As the scope of many of Dr. Russell Reynolds' statements is virtually and by implication a tacit denial of what is above said, I consider myself called upon to reiterate with emphasis my statements in exposure of his unacquaintance with the subject. Under ordinary circumstances this would not have been necessary, but considering the formality attending the delivery of an Harveian Oration at the Royal College of Physicians, the distinction of the audience, and especially the eminence of the orator on the present occasion, I should feel myself as wholly put down for a pretender did I not interpose a few remarks provisionally. In my next communication I shall have to comment more particularly on the shortcomings of Harveian Orations and the disadvantageous position in which Harvey is too often placed by his friends.

May I beg of Dr. Russell Reynolds the favour to study my paper in Guy's Hospital Reports for October, 1850, and then advise with Sir William Jenner and Sir Joseph Lister on what is to be found therein. In October, 1850, Sir William Jenner was a colleague at University College Hospital of both Dr. Russell Reynolds and myself, whilst at the same time Sir Joseph Lister was acting temporarily as my ophthalmic assistant. I showed Sir William Jenner some points of the subject under the microscope. As to Sir Joseph Lister, he studied my paper with great intelligence and interest, as I was able to infer from the pertinent inquiries he made of me in conversation in order to obtain by word of mouth further elucidations of the subject. Sir Joseph Lister may perhaps remember that so intent was he in his inquiries that he one day accompanied me in my walk to the Regent's-park after the conclusion of the hospital visit. In the course of his oration Dr. Russell Reynolds quotes various incidental expressions of Harvey, which he adduces as forecasts of several of the very important physiological discoveries of the present day. But did Dr. Russell Reynolds not consider that if Harvey is to be credited for so much, why not also Cesalpino, for whom half-scientifically informed Italian physiologists claim the honour which is due to Harvey? And did not Dr. Russell Reynolds consider that he was thereby weakening the able and just defence of Harvey, recently published by his colleague, Dr. George Johnson?

It may not be amiss here if I suggest to Professor Redfern of Belfast to put himself in communication with Sir Joseph Lister respecting the effect of contusion of small vessels by pressure with a blunt point, as observed under the microscope, referred to in my previous communication.

Ventnor, Isle of Wight.

CHRONIC CATARRHAL LARYNGITIS:

ITS VARIETIES, WITH THEIR ETIOLOGY, PATHOLOGY, AND CLINICAL RELATIONS.

By GORDON HOLMES, M.D.,

PHYSICIAN TO THE MUNICIPAL THROAT AND EAR INFIRMARY, LONDON
CONSULTING PHYSICIAN TO THE SHEFFIELD EAR AND THROAT HOSPITAL.

(*Continued from p. 821.*)

II. HYPERTROPHIC LARYNGITIS.

THE *subjective* symptoms in this form of laryngitis are much more marked than in the affection just described. Not only is voice modified, but respiration also is sometimes seriously interfered with. Abnormal sensations, cough and expectoration, have also to be considered. *a.* Great and progressive alteration of voice is here present. The laryngeal tones have a deep and muffled character, and give the impression of being produced with difficulty, as if the vocal bands had become incapable of continuous isochronous vibration. The voice, however, generally retains much of its normal tone; we may say that its sonority or intensity is diminished, but its volume increased. An absolutely rough hoarseness is very uncommon. Aphonia may supervene in both sexes, though it is more likely to affect women. *b.* Although in ordinary cases respiration is never seriously

Digitized by Google

impeded, yet in a small proportion of instances dyspnœa supervenes, and may even become so urgent that a fatal termination can only be obviated by tracheotomy. An important example of this kind has been reported by Türck. *b.* A feeling of thickness and as of a lump in the throat is often complained of, but it is by no means a constant sign. Sensations of heat and pricking are also occasionally present, but pain, even on external pressure, is seldom distinctly to be observed. *d.* Cough is very rare, except in the form of voluntary hacking to clear the throat. *e* Expectoration is decidedly less than in simple chronic catarrh. Very small quantities of viscid mucus are ejected after persistent hacking efforts.

The *objective* signs of this disease, though inconstant as to extent, are always very obvious to the laryngoscopist. First, as to hypertrophy, this necessarily is always present, but may vary much in degree, according as the disease is partially or fully developed, limited to certain parts or general. Thus we may observe an almost equable thickening or tumefaction, modifying the whole contour of the larynx, or one portion only of the organ may be involved. In the latter case it is almost invariably one of the ventricular bands that shows an increase of size. In this position a slight disturbance of symmetry at once strikes the eye, but nevertheless the loose tissues of this vicinity and their dependent site favour the occurrence of any kind of swelling. The view of one or both vocal bands may be shut out by the abnormal projection towards the mesian line of the parts above. The tissues covering the arytenoid cartilages and the inter-arytenoid fold are often much hypertrophied. The vocal bands may also be much thickened, losing hence their normal regularity of shape.

According to Mandl[1] the epiglottis is often much swollen in this malady, and by consequent traction folded so as to resemble a horseshoe or *capuchon*. In my experience, however, this condition, though common enough in phthisis, syphilis, &c., is seldom present to such an extent in merely hypertrophic laryngitis. Here, indeed, I think the epiglottis enjoys a comparative immunity from attack.

In some cases the superficial structures forming the oblique surface immediately below the vocal bands are considerably hypertrophied—a condition first observed by Rokitansky[2] and Czermak,[3] and subsequently furnished by Gerhardt,[4] with the rather pedantic name of "chorditis vocalis inferior hypertrophica." This swelling, when pronounced, can be well seen with the laryngoscope, and often produces a concentric narrowing of the passage. In the only case I have met with the excrescent tissues had the pale, translucent, and gelatinous appearance characteristic of the ordinary mucous polypus of the nose. Other writers have made the same observation, and in fact it is doubtful whether this disease is not an affection *per se*, deserving a separate place in laryngeal pathology, instead of being included under the present heading.[5]

Secondly, as to variation in colour, we shall observe a great diversity in different cases. In the milder forms the laryngeal mucous membrane has much the same dull, slightly variegated tint seen in the simple catarrh. On the other hand, when the swelling is great and extensive the whole larynx often displays a vivid red hue, indicating the most active hyperæmia. Between these two extremes every gradation of colour may be noticed, the abnormality of tint bearing by no means always a strict ratio to the actual extent of hypertrophy.

With respect to ulcerations, we meet with the same erosions as occur in the simpler disease, and scarcely with greater frequency. The free edges of the vocal bands are the parts most likely to be excoriated. In addition, however, clefts, creases, or fissures, which often have the appearance of containing raw cracks in the depth of their angle, can be observed. They are mostly situated on the internal wall of the larynx, between the arytenoid cartilages and the interarytenoid fold internally, and the aryepiglottic folds externally. Whether deeper ulcers occur apart from tuberculosis is an unsettled question. The vocal bands are rarely coated with viscid secretion in this affection, but a small amount of frothy mucus occasionally occupies the laryngeal vestibule, to a great extent veiling the parts from view. Alterations of voice depend chiefly on the hampered action of the vocal bands, through the tumefied and hence unyielding state of the surrounding structures. Thus the swelling of the interarytenoid fold prevents close approximation of the arytenoid cartilages, whilst, as Mandl[6] remarks, the vocal bands cannot be drawn widely apart, owing to the abnormal resistance offered by the more or less solidified tissues supporting them externally. In this way respiration also may be impeded. The deep muffled tones of the voice probably result from inability of the vocal bands to vibrate, except *en masse*—that is, weighted with the whole of the thyro-arytenoid muscles, with which the ligamentous portion becomes firmly consolidated.

Pathogenesis.—The causes of this disease, which is mostly primary, are in nearly all instances exceedingly well defined. Persons who are continually exposed to wet and cold, to straining efforts of voice,[7] and to excessive indulgence in spirituous liquors, are almost exclusively liable to attack. Hence it is a malady specially allied to certain occupations, and, with few exceptions, met with in publicans, auctioneers, cab-drivers, and costermongers. Further than this, I would say that hypertrophic laryngitis is rarely seen without a history of alcoholic excess, and this I consider to be not only the most influential, but almost the *creative* cause of the disease. In my judgment, therefore, it might with propriety be called "alcoholic laryngitis." The milder class of cases, however, generally occurring in females, which are scarcely to be distinguished from the simple catarrh, except by the swelling of one of the ventricular folds, are doubtless etiologically similar to the latter affection, being often secondary, or arising from frequent slight colds, &c.

From the foregoing statements, it will be inferred that hypertrophic laryngitis is essentially an affection of the male sex; and in support of such inference, I find that of forty-seven cases of my own, thirty-nine were males, whilst of the eight instances in females only two belonged to the pronounced type of the disease.

As regards age, all my cases occurred between twenty-seven and forty-five, except one in a youth of nineteen and another in a boy of sixteen.[8]

Pathological Anatomy.—We have here in evidence a very complete autopsy by Wedl[9] of Vienna in the case of a man who died suffocated by hypertrophic laryngitis, the sequel of an acute attack, after it had lasted several years. On this authority it is shown that the disease consists of a chronic cell proliferation mainly in the submucous connective tissue, but to some extent in the corium of the mucous membrane. New connective tissue of impaired vitality is thus formed, and hence the malady is essentially an example of a true numerical hypertrophy. Thus, under the microscope, groups of young connective-tissue cells can be seen, along with isolated nuclei, when fully developed. These penetrate to some depth between the muscular fibrillæ and there become agglomerated. The alteration of colour of the surface of the mucous membrane, apart from hyperæmia, is mainly due to opacity from infiltration by a finely granular mass and nuclei in decomposition. The epithelium has its usual characteristics in chronic catarrh, being of stunted growth and low vitality, but rarely shed to such an extent as to give rise to erosions. From his pathological observations Wedl supposed that ulcers penetrating the corium of the mucous membrane would ultimately arise in these cases, but clinical facts are opposed to this view. Such ulcers have not been recognised, and if they exist they have hitherto and are still confounded with laryngeal phthisis.

Diagnosis.—There is but one affection of the larynx that hypertrophic laryngitis runs any real risk of being confounded with, and that is tertiary syphilis in an early or partially developed and indolent state. Incipient laryngeal phthisis, however, of the congestive type often bears considerable resemblance to the less serious malady. In both cases attention to history and collateral symptoms will in nearly all instances quickly dissipate doubts. When the swelling is confined to one ventricular band, there is a similitude to the rare cases of primary cancer of the larynx, which usually begins in this site. The malignant neoplasm is,

[6] Op. cit., p. 668.
[7] That is shouting, not singing, properly so called. Artistic exercise of the voice in excess does not, in my opinion, produce a more serious lesion than the simple chronic catarrh or glandular lesion.
[8] This case was under my care for two months, and had a previous history of several months. The patient was afterwards lost sight of, but when last seen there was reason to suspect the development of phthisis.
[9] Reported by Türck, Klinik der Krankheiten des Kehlkopfes, Wien, 1866, p. 203.

Digitized by Google

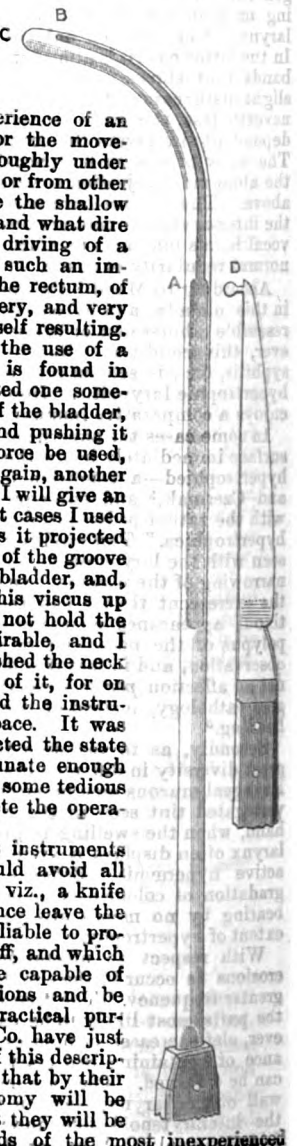
however, as a rule of more recent date, has a more congested, irregular, and "angry" appearance, whilst as it progresses it quickly becomes marked with whitish patches of cream-like scum, and soon after ulcerates.

Prognosis.—When hypertrophic laryngitis occurs, as most frequently happens, in close etiological relationship with certain modes of life, it is evident that our prognosis as to recovery must be unfavourable unless in the presence of a complete change in the occupation and habits of the individual. Should the hypertrophy be so great as to demand tracheotomy in a patient past middle life, a fatal termination in from six to twelve months is almost a certainty. Under these circumstances the patient perishes slowly from debility in a manner bearing a considerable clinical resemblance to phthisis, or perhaps succumbs with little or no vital resistance to an intercurrent malady, such as pleuro-pneumonia. In the less pronounced cases the malady, if left alone, will generally run a progressive course for many years, whilst in the mild instances of accidental origin, mostly seen in females, actual aggravation is rare and spontaneous cure not unfrequent. Some authorities think that the more pronounced and persistent examples proceed by intrinsic force to laryngeal phthisis. Tobold[10] is the chief advocate of this view, and bases his opinion mainly on the results of the experiments of Sommerbrodt,[11] who produced phthisis in squirrels by mechanical irritation of the larynx. The question is not yet cleared up, and in my opinion it remains to be seen whether laryngeal phthisis, as at present defined clinically, will not prove to be still a polymorphous disease, not every instance of which depends on a veritable tuberculosis.

Treatment.—The *constitutional* measures recommended for the simple catarrh, with change to a mild climate during the winter months, must be adopted and carried out with increased assiduity. It must be borne in mind, however, that unless the exciting causes of the disease be removed, when they are manifest, we shall obtain no decided or permanent benefit from treatment, no matter how diligently pursued. Should the climatic exposure, overwork of the voice, or alcoholic excess be continued or resumed, the course of the malady will, *pari passu*, be one of persistence or relapse.

As to *local* remedies, most relief will be obtained from the use of cold spray inhalations (perchloride of iron, sulphate of copper, &c.), but warm soothing inhalations impregnated with opium, conium, stramonium, &c., can often be employed with advantage in the subacute exacerbations of the malady, which are rarely absent in winter. The various astringent lozenges (tannic acid, rhatany, kino, &c.) are of great value for obtaining temporary benefit, before or after using the voice, for instance, and they should be reserved for such purposes. They do not, however, act with sufficient potency to ameliorate permanently this disease, and, if resorted to continuously, will soon lose all efficacy. In the way of local application by the practitioner, the ordinary astringent solutions, especially that of perchloride of iron (two drachms to an ounce of water), can be employed daily with satisfactory results in the milder cases, but in pronounced hypertrophic laryngitis they are of little avail. Under these circumstances we must resort to nitrate of silver, which may be applied occasionally in the solid form to those parts of the larynx most deeply implicated, whilst for daily use a strong solution (one to two drachms to an ounce of water) should be liberally painted over the whole of the affected surface. By persevering in this treatment, we can often in a few weeks obtain a virtual cure in cases which have previously resisted all efforts of a milder type.[12]

In those instances where the sub-glottic swelling is present tracheotomy is almost invariably required, for the position of the lesion almost precludes the possibility of successful treatment *per vias naturales*. Scarification may be attempted, and Voltolini[13] has once obtained a permanent diminution of the tumour by the electric cautery, but this may be regarded as a phenomenal achievement. After tracheotomy the larynx can be dilated by means of bougies or Schrötter's[14] tubes and plugs.



(To be concluded.)

A NEW KNIFE AND STAFF FOR THE SAFE PERFORMANCE OF LITHOTOMY.

BY SURGEON H. W. BOYD, F.R.C.S., M.K.Q.C.P.I.,
BOMBAY MEDICAL DEPARTMENT.

HAVING had a large experience of stone cases in India, and seen in some instances the deplorable results and the irreparable injury following on the accidental slipping of the knife from the groove, or the protruding of its point beyond the end of the staff during the operation of lithotomy, I was led to consider whether a knife might not be devised which would avoid all danger from these causes. I am sure most practical lithotomists will agree with me that the only real danger in the extraction of a stone by lithotomy (outside the large size of the calculus), in an otherwise healthy subject, depends upon the direction and extent of the deep incision. It can be readily understood how easily, owing to the inexperience of an operator or his timidity, or the movement of a patient not thoroughly under the influence of chloroform, or from other causes, the knife may leave the shallow groove of an ordinary staff, and what dire results may follow on the driving of a sharp-pointed bistoury into such an important region: wound of the rectum, of the prostate, of the pudic artery, and very frequently of the bladder itself resulting. Nor is danger confined to the use of a sharp-pointed knife, for it is found in practice that the probe-pointed one sometimes fails to nick the neck of the bladder, its blunt point hitching in and pushing it up before it, and, if much force be used, tearing the urethra across. Again, another accident may occur, of which I will give an illustration. In one of my first cases I used a probe-pointed knife, and as it projected considerably above the edges of the groove it caught at the neck of the bladder, and, instead of cutting, pushed this viscus up before it. My assistant did not hold the staff as steadily as was desirable, and I found that I had actually pushed the neck of the bladder over the end of it, for on introducing my finger I found the instrument in the recto-vesical space. It was some moments before I detected the state of the case, and I was fortunate enough to reintroduce the staff after some tedious manipulation, and to complete the operation.

I have often thought that instruments could be made such as would avoid all dangers of the above nature: viz., a knife which could not by any chance leave the groove, which would not be liable to project beyond the end of the staff, and which at the same time would be capable of making the necessary incisions and be sufficiently handy for all practical purposes. Messrs. Fannin and Co. have just completed a knife and staff of this description for me. I am confident that by their use the operation of lithotomy will be infinitely simplified, and that they will be found harmless in the hands of the most inexperienced operator.

The staff is much the same as an ordinary one (as can be seen from the accompanying woodcut), the only difference being in the groove, which in the perineal portion of the instrument is wide, to admit the entrance of the button (D) on the back of the knife, but towards the curved part it narrows (see A) so as to grasp this button and prevent the knife slipping. The groove (B) ends about a third of an inch from the extreme point (C). With reference to the position of this groove,

Digitized by Google

it may be placed on any aspect of the staff. The one shown in the woodcut is on the posterior aspect, but one may be made with a groove on the side if desired, or commencing posteriorly, and, taking a semi-spiral direction, ending laterally; and I think this form of staff would be most suitable, as the knife in passing along lateralises the incision without demanding any attention from the operator. Lastly, by approximating the edges of the groove of Buchanan's angular staff, and leaving the angle open to receive the button, an excellent arrangement may be made.

With reference to the knife, it does not much differ from a finger knife in shape, only it has projecting from the back of the blade, and about a line from its point, a small button attached to the blade by a narrow neck. This button can enter any part of the perineal portion of the staff, but as it passes on towards the narrow portion of the groove it engages in the staff and ultimately stops a third of an inch from its point, where the groove ceases. In the narrow portion of the groove the knife can be lateralised to an angle of 45°, so that it admits of plenty of play and movement during the operation. To perform this the external wound may be made by either transfixion or cutting. The perineal portion of the instrument being thus exposed, the button is placed in the groove and the knife pushed on into the bladder. If the existence of only a small stone be suspected, the back of the knife may be kept close to the staff, when only a moderate incision will be the result; but if a deeper incision be required, as in cases where a large stone has to be extracted, then by depressing the instrument while pushing it into the bladder any sized incision may be made in the perineum; whereas, owing to the top of the knife being necessarily held in the groove of the staff only, a limited incision in the prostate and neck of the bladder can result. Thus there will be no danger of cutting through the capsule of the prostate, or too deeply through the neck of the bladder, accidents which I am sure frequently occur under the present system of making an incision while withdrawing the knife.

The advantages I claim for this knife and staff are—first, that it simplifies the operation of lithotomy, whether it be the median or the lateral method, and that in the hands of the most inexperienced the operation can be performed with expedition; secondly, that it obviates all tendency on the part of the knife to slip, thereby preventing some of the most frequent causes of death following on this operation; and, thirdly, that the protrusion of the knife beyond the point of the staff with consequent puncture of the posterior part of the bladder is rendered impossible. In conclusion, I trust these instruments will be found valuable, especially in countries where calculus is prevalent, and where skilled medical aid may not be near at hand, where often the operation has to be performed to save life by men to whom the operation is new, or whose timidity may be a bar to its performance.

Dublin.

MITRAL STENOSIS AND INSUFFICIENCY.

By T. C. RAILTON, M.D. LOND.,
SENIOR ASSISTANT PHYSICIAN TO THE MANCHESTER CLINICAL HOSPITAL FOR WOMEN AND CHILDREN.

THE following notes of a case of mitral disease may be useful as showing how very important symptoms may be sometimes masked by other conditions, and the diagnosis thereby rendered difficult. They show as well, in a tolerably typical manner, the picture of the heart's gradual restoration from asystolism to comparative well-being, with the disappearance concurrently of all the symptoms depending upon the former state.

T. W——, aged thirty-two years, book-keeper, came under treatment on March 10th. His father died from heart disease and bronchitis at fifty-four years of age, but there was no further history of rheumatism or heart disease in the family. Although always troubling himself a good deal about business and working hard, the patient had considered himself to be a healthy man until quite recently, with the exception of three attacks of bronchitis which he had suffered from during the past winters, the cough, however, disappearing when the warm weather came. So far as he knew, he had not been under the care of a medical man, he had never suffered from rheumatism, from shortness of breath, nor had he lost flesh. During the last month he had taken cold and had a cough, with occasional hæmoptysis and shortness of breath, but he continued at his business until two days before coming under treatment, when his increasing disorder compelled him to remain in bed. When first seen he was found to be suffering very considerably from dyspnœa, which was aggravated by the slightest exertion. He had to be propped up in bed, and was much distressed by a constant hacking cough, bringing up a sputum tinged with blood. He had no signs of congestion in the face, being quite pale. He was perspiring freely, and there was a sour smell present, like that of acute rheumatism. He had, however, no elevation of temperature and no joint affection. There was no œdema of the extremities nor any perceptible ascites, but the abdomen was considerably swollen over the region of the liver. His fingers and toes were very decidedly clubbed at their ends. On examining the chest, it was found to be well-developed, with both sides equal; the percussion note was almost tympanitic except at the base of the right lung posteriorly, where there was comparative dulness. A few râles were to be heard scattered over the chest, and bronchial breathing in that part where the dulness existed. The superficial cardiac dulness was found to be perfectly normal; the apex beat was diffused and weak, but situated somewhere about the nipple-line in the fifth interspace, at which spot a faint presystolic thrill could just be perceived. On auscultation at the apex the first sound was remarkably short and flapping, and was not followed by any second. There was an exceedingly short and slight roughness to be heard immediately preceding the first sound, which might almost have escaped attention had not the presystolic thrill pointed out its nature. At the base there was a reduplication of the second sound, in the aortic area it was weak, in the pulmonary area it was but very little stronger. There was no tricuspid disease discoverable. The liver was found to be uniformly enlarged, but there was no pulsation or any great degree of tenderness. The dulness in the right nipple-line was six inches and a half in depth. The spleen was apparently somewhat enlarged. The urine was scanty and loaded with urates; it contained a considerable quantity of albumen. The treatment adopted was to keep the patient perfectly quiet, to supply him with a nourishing diet, more particularly Benger's peptonised beef jelly, and to administer half an ounce of the Pharmacopœal infusion of digitalis every three hours.

I need not occupy space by detailing the daily progress of the case; it will be sufficient to mention briefly the changes in the various organs implicated. The dyspnœa began to abate in the course of twenty-four hours after beginning the digitalis, and had entirely left him in three days. The sputum tinged with blood disappeared at the same time. The sweating was noted as much less by the fourth day, at which time also the liver dulness was found to be diminished. On the sixth day the size of the liver had become quite normal. At the same time that portion of the right lung which had been compressed regained its normal resonance and breath sounds. The urine was clear and free from albumen on the third day. As regards the heart, although its action continued to be irregular during the whole attack, and in fact has remained so since, the pulse became stronger in the course of two days, and with the improvement in the nutrition of the cardiac walls the sounds underwent the following modifications. On the third day the murmur at the apex, from having been genuinely presystolic in rhythm, was noted to have changed so as to occupy the whole of the ventricular pause, the second sound being still absent. It was very rough in character. The next day, the rhythm and everything else remaining the same, the roughness had changed to a loud rumble. On the fifth day the aortic second sound was to be heard at the apex for the first time, and was immediately followed by the rumbling murmur, which, however, no longer extended quite to the beginning of the first sound, thus becoming post-diastolic in rhythm. The second sound at the aortic cartilage was noticed to be louder than before. On the sixth day a faint systolic murmur accompanying the first sound was heard just at the apex, not traceable to the axilla or back, the post-diastolic murmur remaining as before. In this condition the heart has remained up to the present time, when the patient has been compelled to resume his occupation. All the sounds are stronger; at the base the aortic sound is normal, the pulmonary sound accentuated.

Remarks. — The absence of abnormal cardiac dulness

Digitized by Google

might have rendered the diagnosis obscure if the other symptoms had not pointed so strongly to cardiac insufficiency. No doubt the enlargement of the right ventricle and left auricle is masked by an emphysematous condition of the lungs, the result of the previous attacks of bronchitis. The insidious advent of the disease, without any previous history of rheumatism, and its long existence (as shown by the clubbed ends of the fingers and toes and by the extent of the mischief in the heart itself), without having attracted attention, hardly require comment, both of these circumstances being common in this form of valvular mischief. It is worth noting, however, that after a long period of immunity the rupture of compensation was brought about with the greatest rapidity by an attack of cold. I would draw attention to the alteration in rhythm of the obstructive murmur under the influence of rest and digitalis. At first a true presystolic murmur, it changed so as to occupy both diastolic and presystolic periods, and later the diastolic period only. These changes were coincident with an increase in the strength of the walls of the left ventricle, as shown by the improvement of the aortic second sound, its conduction down to the apex, and by the appearance of the systolic mitral murmur. It is quite reasonable to suppose that by strengthening the ventricular walls their diastolic power will be increased in the same ratio as their systolic power, and this permits us to make use of Dr. Broadbent's hypothesis that the post-diastolic rumble may be produced by the blood being strongly drawn from the left auricle, through the narrowed mitral opening during the active dilatation of the left ventricle. This will account for the production of the diastolic or post-diastolic murmur, but will not explain the absence of the presystolic portion of the murmur at a time when other signs showed the heart to be acting strongly. It would seem that the increased power of the left ventricle to fill itself during the diastolic period resulted in a condition modifying the vibrations of the mitral valve during the presystolic period and so rendering them inaudible. A question of great interest in mitral stenosis is the almost characteristic loud and short first sound. It has been aptly compared with the second sound in quality, and appears to owe its shortness, like the latter, to the fact that it consists of a vibration of the valves unaccompanied by muscular bruit. The absence of tone in the walls of the left ventricle particularly is to be explained by the small amount of blood which has habitually reached it in a long-standing case of mitral stenosis, like the one we are considering, and may thus account for the imperfect contraction of the muscle. As regards the loudness of the sound, sometimes so extreme that one can hear it without a stethoscope eight or ten inches from the chest, it is difficult to explain unless we accept Dr. Broadbent's suggestion that, "it is due to imperfect distension of the ventricular cavity and the consequent absence of resistance at the beginning of the systole."[1]

ST. THOMAS'S HOSPITAL.

TRAUMATIC DISLOCATION OF HIP; USELESS LIMB; EXCISION OF HEAD OF FEMUR; SUCCESSFUL RESULT.

(Under the care of Mr. SYDNEY JONES.)

THE following case is especially interesting when taken in conjunction with the recent discussion at the Royal Medical and Chirurgical Society (see THE LANCET, Nov. 1st, p. 775).

A. R——, aged eleven, in May, 1879, met with an accident, and dislocated his right femur on to the dorsum ilii. One dislocation was recognised, and is said to have been reduced. A splint was applied. When this was removed, the head of the femur was still on the dorsum. Several attempts were made to reduce the dislocation, but without success. The patient came under Mr. Sydney Jones's care in October, 1879. Three attempts, by manipulation and pulleys, were made at reduction, but to no purpose. The limb was useless for progression on account of the shortening and inversion. On Nov. 25th, 1879, Mr. Sydney Jones excised the head of the femur, corrected the malposition of the limb, and drew down the upper end of the shaft to the acetabulum, which was filled up with condensed cellular tissue and inflammatory material. Now, five years after the excision, the boy has a straight limb an inch shorter than the opposite one. He can run, jump, play cricket, and ride a tricycle.

CITY OF LONDON INFIRMARY, BOW.

ANEURYSM OF THE LEFT SIDE OF THE ABDOMINAL AORTA BURSTING INTO THE BLADDER AND SIMULATING AN AFFECTION OF THE CÆCUM.

(Under the care of Mr. W. GEM.)

WILLIAM G——, aged forty-five, carpenter, was admitted on Dec. 27th, 1881, for rheumatic pains in the right hip and colon, and discharged well on Jan. 16th, 1882. He was readmitted on Nov. 29th, 1883, for injury of the hip and elbow-joint of the right side, discharged well in January, 1884, and again readmitted on Sept. 15th, 1884, with rheumatism of the right side and obstinate constipation. On this last occasion he confessed that he had been of intemperate habits, and was under the influence of drink when he received the injury to the hip and elbow. He appeared not to have been exposed to wet or cold at any time, but had always worked at his trade as a carpenter, not of a laborious character.

On examination of the abdomen over the right iliac fossa and linea alba, a tumour could be felt and seen, which on percussion appeared dull, and on deep pressure caused considerable pain, with sickness; it was about the size of an orange, and transgressed the median line, appearing to be in direct contact with the bladder. The patient complained of throbbing pain shooting down to the right testicle, no bladder symptoms being complained of until about two days before death on catheterisation. No alteration in the colour or constituents of the urine was visible; nor was there pain or uneasiness experienced on the left side; and no pulsation or dulness on percussion over the left lumbar or iliac regions could be made out. On stethoscopic examination over the abdomen no bruit could be detected.

The treatment adopted was perfect rest in the recumbent position, with milk diet. The bowels were first acted on with calomel, colocynth, and hyoscyamus, in pill, which gave him great relief—in fact, he appeared very much better after the purgation; the bowels were afterwards kept free by castor oil. It may be added that on admission the patient was ordered a bath, which caused fainting, and on examination over the mitral valves a systolic murmur was heard and the bath immediately stopped.

On Sept. 26th the patient complained of great pain over the right iliac fossa and obstruction of the bowels, with a feeling of sinking, for which he was ordered fomentations, with brandy and opium. From that date the patient gradually sank and died. On Sept. 30th, twelve hours before death, the urine was drawn off, and was then perfectly normal in colour.

Necropsy.—The surface of the body was blanched, except the tip of the nose, which was in a gangrenous condition (which commenced two days before death). The lungs were normal. There were slight atheromatous patches on the cusps of the mitral valves. The liver was cirrhosed. The right kidney and spleen were normal; the left kidney had an old abscess at the superior margin. There was localised peritonitis between the folds of the peritoneum and the intestines. On removal of the bowels a large black-looking mass presented itself, extending from opposite the eleventh and twelfth dorsal vertebræ to Poupart's ligament, and in direct contact with the bladder, lying above the kidney, bound down by the lumbar fascia, the ureter remaining intact. The bladder on being opened was found to contain clotted blood, and fully distended; on turning out such clot an opening was found on the posterior and left wall, in direct communication with the tumour; it was soft and friable, and broke down under pressure of the finger, like brown paper. There was no erosion of the vertebræ or destruction of any viscus except the bladder, which was as above stated. The sac of the aneurysm contained

[1] Harveian Lecture, November, 1883.

Digitized by Google

organised laminated fibrine, of two or three layers of different thickness.

Remarks.—I consider the above case unique, inasmuch as on referring to Quain's Dictionary and Aitken and Roberts' Medicine, I fail to find any mention of an aneurysm opening into the bladder, with normal coloured urine twelve hours before death. The other points of interest are, the whole of the symptoms being referred to the right side and right testicle, and the tumour in the right iliac fossa, with pain and throbbing, with a distinct tumour in that situation, and also the disastrous consequences that might have occurred on catheterisation. How is it explained, unless the lumbar nerves on the left side were so compressed as to cause their destruction, and the right side being intact the pain was referred to the right side, either by decussation or by direct communication, or whether it was transmitted to the cord from the left nerves, and to the right through that medium, is a moot question?

TAUNTON STATION HOSPITAL.

ULCERATIVE ENDOCARDITIS; NECROPSY; REMARKS.

(Under the care of Brigade Surgeon HENSMAN.)

PRIVATE J. M——, fourth battalion Somersetshire Light Infantry, was admitted on March 23rd, 1884. He complained of diarrhœa, from which he had been suffering for some days, and of some cough, but had no pain or shivering. His temperature at 10 A.M. was 102°, and in the evening 105°. He had a feverish, heavy look, a congested face, and a petechial eruption over both lower extremities. Three drops of tincture of aconite were given every two hours, and an enema of starch. Ordered milk diet and two pints of beef-tea. The progress of the case was as follows.

March 24th.—Since the starch enema there has been no more diarrhœa; he coughs, but has no pain or expectoration; resonance is impaired in right back; a double cardiac bruit exists, and an extended cardiac area to percussion; the apex beat one inch outside, and two inches and a half below the left nipple; the liver and spleen both enlarged and easily felt on palpation. The urine is found to be acid, sp. gr. 1018, with considerable albumen. Pulse 140; respiration 40; morning temperature 105·5°. Thirty grains of quinine were given at 10 A.M., and the temperature fell two degrees.

25th.—The symptoms were the same. Temperature 105°; pulse 140; respirations 40. Quinine repeated.

26th.—Seven stools in the twenty-four hours. No iliac tenderness; no rose-coloured spots; the belly flaccid. He is in no pain. Tongue dry; rhonchus down both backs. Temperature 105°; pulse 115; respiration 36. Two grains of quinine and ten drops of tincture of digitalis every four hours. Ordered enema of starch and opium, milk, beef-tea, and eight ounces of port wine.

27th.—Great prostration; bowels relaxed; tongue dry and black; aphonia; subsultus; wandering delirium. Treatment to be continued.

28th.—Death occurred quietly, comatose.

Necropsy, twenty-four hours after death.—External appearances: The petechiæ had become more diffused, and the skin had a yellowish tint. Thorax: Pericardium entirely adherent by old adhesions; muscular structure of heart hypertrophied; valves on right side healthy. On left side the curtains of the mitral were much thickened by old-standing disease. On the free edge of the valve were three small ulcers, and on the ventricular aspect just below a segment of the aortic valve an erosion as large as a threepenny piece, the endocardium around it having a bright-pink colour. This large ulcer showed a very considerable loss of tissue; the cusps of the aortic valve were thickened and corrugated; there was no appearance of atheromatous deposit in the aorta; two of the chordæ tendineæ were beaded with minute vegetations, and recent granular fibrine appeared in the neighbourhood of the ulcers. This valuable specimen now forms part of the collection in the museum at Netley. Lungs congested; structure appeared healthy. Old pleuritic adhesions on both sides, tearing away parietal pleura on separation. Abdomen: Liver enlarged, congested; weight 5 lb. Spleen large, black, soft. Large soft infarcts found in both organs. Intestines: The cæcum and colon were inflamed and marked with dark hæmorrhagic patches; in the ascending colon were two small paches of necrosis, three-quarters of an inch in diameter, not perforating. There was no peritonitis. Ileum and small bowel unaffected. There was an absence of any enlargement of Peyer's glands and there were no enlarged mesenteric glands. Kidneys: Pale, smooth, and large capsule easily separable; surface speckled with innumerable hæmorrhagic points, the site of small infarctions. The section had a pale appearance, and a yellowish streaky infiltration took the place of some of the pyramids.

Micro-organisms.—The assistant professor of pathology at Netley, Surgeon-Major Dr. Timothy Lewis, demonstrated numbers of micro-organisms in the endocardial ulcerations. Both Professor Aitken and Dr. Lewis agree that there is nothing specific in the appearance of these micro-organisms, and that they are the ordinary bacteria of necrotic lesions.

Remarks.—The ulcers in the endocardium appeared to me as if they had existed some time, and were not of simultaneous occurrence with the more recent endocarditis, or with the man's last illness; the petechial eruption had been noticed a week or ten days prior to his admission to hospital. Two cases of violent acute inflammation of the lymphatics of the arm occurred from post-mortem inoculation from this body; the first happened to my hospital sergeant who assisted at the autopsy, and pricked his finger with the scissors; in twenty-four hours the wound inflamed and the inflammation ran up the arm to the axilla; deep abscess occurred in the hand. The second was the undertaker who assisted to lift the body into the coffin, and the moisture upon the body inoculated a small abrasion he had upon his hand. Similar violent symptoms followed as in the former case, and his life was despaired of; abscesses formed; he lost a portion of the finger and was ill for three months with useless hand and arm. I presume that, in this case, the micro-organisms were the cause of the embolisms in the skin, bowel, liver, spleen, kidneys, &c., and their extremely virulent character the cause of the violent inflammation of the lymphatics following post-mortem inoculation from the body. In these latter cases general septic infection seemed to be prevented entirely by the action of the axillary glands arresting the further progress of the poison towards the circulation.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Expiratory Cervical Emphysema.—Malignant Stricture of Œsophagus with Pulmonary Cavity.

AN ordinary meeting of this Society was held on Tuesday last, Dr. George Johnson, F.R.S, president, in the chair.

A large number of candidates for the fellowship offered themselves for election.

Dr. FRANCIS HENRY CHAMPNEYS read a paper on Expiratory Cervical Emphysema, otherwise styled emphysema of the neck occurring during labour and during violent expiratory efforts. It was an experimental inquiry, and was complementary to the previous inquiry dealing with emphysema of the anterior mediastinum after tracheotomy (vide THE LANCET for 1882 and the Medical and Chirurgical Transactions, vol. lxv., pp. 75–86). Healthy fœtuses were used, with two exceptions, in all the experiments. With regard to frequency the accident occurs about once in two thousand labours. Etiologically it is agreed that the cervical emphysema is caused by bearing down, which is only another name for violent and prolonged expiratory efforts. It occurs during the second stage of labour, and generally appears first at or about the suprasternal notch, whence it may extend in all directions. In its clinical course it was never accompanied by pneumothorax; it becomes absorbed within a week or so and seems always to end favourably. As to the pathological theories, it has been attributed to rupture of the (1) bronchi, (2) trachea, (3) lung. Three autopsies supporting the third view were given; the other opinions seem to be unsupported by facts.—*Mode of experiment:* Tracheotomy was performed, and the trachea connected by means of T-tubing with a mercury manometer, leaving an open tube for inflation. Seventeen experiments were performed, some with the lungs *in situ*, others with the thorax open, others with the lungs removed from the chest. In one an attempt was made to trace the course of the air by means of a coloured gelatine mass. The conclusions from the experiments were the following:—1. The cause of emphysema of the neck during labour is

Digitized by Google

rupture of the lung tissue, the air escaping near the root of the lung, passing beneath the pulmonary pleura into the anterior mediastinum, and so beneath the deep cervical fascia into the neck. The route thus marked is the same by which air sometimes passes into the anterior mediastinum after tracheotomy (vide Medical and Chirurgical Transactions, vol. lxv., 1882, p. 75, *et seq.*, and p. 85). 2. The weakest parts of the lungs are opposite the pleural reflections—i.e., the spaces between the lobules and the fissures between the lobes, and especially the anterior surface of the root of the lung. 3. Pneumothorax, when it occurred during experiment, had nothing to do with the production of emphysema of the neck. The healthy bronchi and trachea are able to resist the greatest possible expiratory efforts. 4. The lungs and pleura, when quite air-tight, are freely permeable to fluids. 5. The usual rules of practice, to restrain bearing down and accelerate labour after the production of emphysema of the neck, are sound. 6. The accident would seem to be noted in about one case in 2000, but it is not improbable that slight cases are overlooked. 7. The air emerges from the thorax along the great vessels, but may not become superficial till it has travelled higher up. 8. The emphysema of the lower part of the trunk, usually connected with rupture of the uterus, belongs to quite a different category, and is generally associated with a fatal result.—Dr. ANGEL MONEY referred to the part played by the pleura, which was a very resisting structure.—Mr. R. J. GODLEE spoke of the reasons which might account for the compressibility of the mediastinal tissues; the presence of vessels from which the fluids could be expressed was thought to be one factor in the compressibility. It would be interesting to know why the air should escape into the anterior mediastinum rather than beneath the costal pleura. He suggested that the experiments should be repeated in adults because the tissues would be more like those of parturient women.—Dr. DOUGLAS POWELL thought that the experiments had a wide bearing. He objected to the use of the term "pleural reflections," as being a new phrase, and as hardly expressing the condition of the pleura where it passed over the interlobular spaces. The weak spot of the chest was generally held to be the anterior margin of the lungs. He inquired how it was that a pressure of at least forty millimetres of mercury was required to produce rupture of the lungs, whereas in the adult even a pressure of three inches and a half was probably the greatest which obtained during prolonged straining. Driving the air towards the trachea, and a reflection of the air towards the lungs, were what occurred during violent efforts of straining. The anterior margin of the lung was that part which usually gave way in his experience of subpleural emphysema. He thought that emphysema was not common at the root of the lung. He had also found by experiments that the lungs were more distensible than the thorax, and that they could be distended a good deal beyond the dimensions of the thorax.—Dr. GEORGE JOHNSON inquired what influence the use of anæsthetics might have in preventing the voluntary efforts which were probably the cause of the emphysema.—Dr. BERNARD O'CONNOR asked whether the "ruptures" had only been found at the anterior surface of the root of the lung.—Dr. SILVESTER was interested in surgical emphysema from its importance in inflating the whole body, thereby rendering the body able to float. The distension of the skin could not be accomplished by powerful expiratory efforts, and, although one sort of lizard had been credited with this power of inflation, yet no animal in existence had proved to be capable of doing so. In his experiments with water he found that the fluid went freely through the tissue of the lung. He could not get either air or water to pass into the cellular tissues.—Dr. CHAMPNEYS, in reply, said that unquestionably the use of an anæsthetic would diminish the bearing down, but the accident occurs suddenly and unexpectedly. The termination of labour would be correct treatment if the emphysema threatened to be extensive. In his experiments he could not imitate bearing down efforts on the dead body, and failed to see how bearing down could be more closely simulated. The small amount of force that was necessary in his experiments was rather an advantage than otherwise. He considered that the intermittent blowing up of the lungs did serve as an illustration of what occurs during "bearing down." With regard to the compressibility of the mediastinum, he could not fully explain why it was the most compressible structure, but he thought that the fluids were driven out more easily than any other of the thoracic contents, and probably the mediastinal fat could be forced up into the lower depths of the neck. He did not say that rupture of the lung was favoured, but that the arrangement of the mediastinal structures favoured the escape of air in that direction when the lung had been ruptured. It must be remembered that some lungs ruptured very easily, whilst others were more difficult of laceration. The bubbles of air did not appear at the anterior edge of the lung, and they were found so often at the anterior surface of the root that he concluded this was the weakest spot. With regard to relative distensibility of the thorax and lung, what he meant was that the thorax allowed the lung to be ruptured inside it. He said that the anterior surface was not the only spot which gave way. The experiments were not claimed to be anything more than illustrative.

Dr. CAYLEY exhibited a specimen of Malignant Stricture of the Œsophagus associated with a Cavity in the Lung, which was treated by thoracentesis. The patient was a man aged thirty-five, who had suffered for five months from symptoms due to œsophageal stricture. After a time pleurisy set in and he expectorated fetid pus. The first time that exploratory puncture was practised with a fine trocar and cannula the cavity at the base of the left lung was not struck. On a second occasion the trocar reached the cavity. At the autopsy it was found that the fluids burrowed from the diseased stomach and œsophagus into the pulmonary cavity. The operation relieved the distress due to the fetid expectoration. The œsophagus exhibited a cancerous ulceration over the lowest three inches of the œsophagus, and involved the cardiac end of the stomach. A continuity of space existed through the spleen and diaphragm into the left base of the lung, where there was a gangrenous cavity.—The PRESIDENT remarked on the unusually long course of the cancerous tract.—Dr. DOUGLAS POWELL spoke of an interesting physical sign, which he had observed over the situation of the base of the left lung at one point. After the patient had swallowed a mouthful of water and given a slight cough there was to be heard a curious "rippling tinkle." He referred to the difficulty which surgeons had experienced in hitting off a cavity which physicians had diagnosed. In cases of hepatic abscess it was difficult to find the abscess by exploration with a trocar.—Mr. GODLEE also spoke of the difficulty which sometimes existed for the surgeon, both as regards pulmonary and hepatic abscesses.—Mr. PEARCE GOULD said that when he first saw the case he introduced a trocar and pierced the tissues in different directions at considerable depth without finding the cavity; yet the patient's suffering was not increased. He thought it was an encouraging case for those who were interested in the progress of pulmonary surgery.

MEDICAL SOCIETY OF LONDON.

Surgical Scarlet Fever.—Spontaneous Amputation.

AN ordinary meeting of this Society was held on Monday last, Mr. Arthur E. Durham, F.R.C.S., President, in the chair.

Dr. DE HAVILLAND HALL read a paper on a case of Surgical Scarlet Fever. The patient was a girl, aged six, admitted into Westminster Hospital for caries of the lower end of the tibia, an operation for which was followed the day after by high fever, the temperature reaching 104·8°, and a bright scarlet rash was seen nearly all over the surface of the body. The tongue showed enlarged red papillæ; the rash lasted four or five days; the temperature was nearly normal on the second day after the appearance of the rash; cold sponging had been used, and desquamation followed, and was marked twenty-six days after the rash had first been seen. The course of the wound was unaffected by the complications. Dr. Hall adopted the view that the poison had been imbibed before the operation, but would not have manifested its effects so soon, if at all, unless the patient's health had been disturbed, as Sir James Paget holds. The rapid fall of temperature was considered to be due to the cold sponging. The difficulty of diagnosis, and the influence of the scarlet fever, on the progress of the wound were discussed. The condition of the tongue was said to give the most trustworthy information in arriving at a diagnosis.—Mr. FRANCIS MASON was not clear that the rash was due to scarlet fever; he thought that some rashes were brought out by an anæsthetic. Other instances were mentioned in which the rash and other symptoms served

Digitized by Google

to indicate an "explosion," as when after a fracture a man gets for the first time an attack of gout.—Mr. BOWREMAN JESSETT thought that Dr. Hall had not proved his point, even supposing that the fever was scarlet fever, might it not be a question of coincidence?—Dr. BRAXTON HICKS said the real question was whether there was such a thing as a rash occurring after an operation, or after parturition resembling scarlet fever and yet not identical. He mentioned the occurrence of scarlatiniform rash in connexion with abscesses in various situations.—Sir JOSEPH FAYRER said he did not know whether an operation could develop such a specific disease as scarlet fever; he preferred to regard the case as one of scarlet fever occurring in a surgical patient.—Mr. R. W. PARKER was of opinion that the case was one of ordinary scarlet fever. At a children's hospital the occurrence was by no means rare in surgical cases which had recent wounds. His experience showed that the scarlet fever might be very virulent, and that the wound might take on fresh action.—Dr. C. THEODORE WILLIAMS asked whether Dr. Hall had ever come across cases which had not been in possible contact with cases of scarlet fever.—Mr. H. CARTWRIGHT spoke of the importance of the nervous system in the production of rashes after operations. He related a case of recurrent erythema, each attack of which appeared to be due to a dental operation.—Dr. W. DUNCAN thought there were two kinds of rashes which occurred in the course of lying-in; one due to true scarlet fever, others merely erythemata.—Dr. BRAXTON HICKS, in reply to a question, said that rashes had the greatest variability in puerperal women.—Mr. BRUNTON had met with at least four cases of genuine scarlet fever which arose spontaneously a few days after parturition.—Mr. DUBHAM had seen cases of surgical scarlet fever, which, in his opinion, were really of the nature of scarlet fever.—Dr. DE HAVILLAND HALL, in reply, said the general opinion was that the course of the wound was unaffected by the occurrence of the scarlet fever. He did not mean to imply that operations could give rise to such a specific disease as scarlet fever. He thought it was important that students should know that patients with wounds were more susceptible to scarlet fever than other individuals. Under the antiseptic system of treatment the cases of surgical scarlet fever were as frequent as under the old system of treating wounds. He considered that desquamation was an evidence of scarlet fever.

Mr. ROGERS HARRISON read a paper on a Peculiar Case of Spontaneous Amputation. The patient was a gentleman, aged seventy-eight, who suffered from extreme pain in the leg, which came on suddenly. When seen by Mr. Harrison the limb was cold, tense, and painful with blackness of the end of the big toe; the signs were probably due to embolism of the femoral artery. Six months after the beginning of the disease the mummified sequestrum, consisting of foot and leg, broke off of its own accord. The stump was trimmed and the gentleman made a good recovery. Sir Joseph Fayrer had told him that the disease was common in India.—Dr. THOROWGOOD asked whether there was any disease of the valves of the heart.—Dr. HARE testified to the fact that there was no suspicion of heart disease, though there was an intermittent pulse.

LEEDS AND WEST-RIDING MEDICO-CHIRURGICAL SOCIETY.

AT the meeting held on November 7th, Dr. Bell, the President, in the chair,

Mr. MAYO ROBSON showed a case of Ununited Fracture of the Femur which, twelve months after the original accident, he had wired together and he refreshed the ends of the bones by silver wire suture, with an excellent result, the man being able to walk several miles less than six months after the operation without pain or discomfort. The operation, which was a somewhat difficult one, was performed strictly antiseptically, and the wire was removed by a second incision three months afterwards, the bone then being firmly united.

Professor T. R. JESSOP exhibited a boy, aged eleven, on whose, in May last, he performed a plastic operation for the closure of an unhealed burn. After an injury received four years and a half ago the skin on the posterior and lateral aspects of the joint refused to heal, over an area measuring 6½ in. by 4½ in. The elbow was ankylosed at a rather acute angle, but the hand and forearm were sound and useful. A flap 6 in. by 4 in. of skin and subcutaneous fat was dissected up from the front of the abdomen in such a manner that its attached base corresponded with a line drawn from the ribs to the crest of the ilium. This was loosely secured by sutures to the granulating wound, the limb being firmly fixed to the trunk in a convenient position. Union took place immediately, and the base of the flap was severed from the abdomen forty-two days after the operation. The result showed the elbow covered with a thick flap of sound skin surrounded by an almost completely healed scar. Mr. Jessop recommended that the wound to be covered should not be refreshed, as in previous cases he had found such treatment followed by delay in union.

Mr. HARTLEY gave a practical demonstration on the use of a 2 per cent. solution of Hydrochlorate of Cocaine on the Eyeball. In a few minutes after a drop had been placed in the conjunctival sac the eyelids could be separated by a speculum and the eyeball manipulated with complete absence of pain on the part of the patient. Mr. Hartley had used the cocaine in many instances for minor eye operations with great advantage, but found its effect did not extend to the deeper structures.—Dr. LITTLE, Prof. EDDISON, and Mr. WARD took part in the discussion.—Dr. CLIFFORD ALLBUTT mentioned that he had used it advantageously for laryngoscopic work.

Dr. BARRS showed a girl, aged twenty, suffering from Addison's Keloid or Morphœa affecting the right hand, the left shoulder and arm, the abdomen, and the left foot. The affection had existed since the second year after birth.—Dr. GRIFFITH thought the diseased patches followed the course of certain cutaneous nerves derived from the posterior cord of the brachial plexus.

Mr. M'GILL showed a patient on whom he had performed Cholecystotomy, removing about five ounces of bile and a stone the size of a pigeon's egg, firmly impacted in the bile-duct. The fistula healed in twenty days, and the patient was completely cured. The operation was done antiseptically and the temperature never rose above 100° F.

Mr. ATKINSON showed a case of Dislocation of the Astragalus Backwards and Inwards. The patient, a man of twenty-nine, had fallen two yards on to his feet three weeks ago. The astragalus is now felt filling up the hollow beneath the tendo Achillis and obliterating the prominence of the heel. The posterior surface of the bone projects backwards and inwards. Behind the scaphoid a pit is felt where the head of the astragalus should be. He can now walk fairly well, but there was much pain and swelling at the time. This form of dislocation is rare, only seven recorded cases being mentioned by Erichsen; it is probably always the result of a fall, combined with a twist of the foot inwards, which forces the head of the astragalus outwards. The case was seen too late to render any attempt at reduction successful.

Mr. J. A. ERSKINE STUART described a case of Neuroma complicating Acute Rheumatism. The tumour, which had existed for twenty-nine years, was situated on a small cutaneous nerve on the back of the forearm. In an attack of acute rheumatism, besides affecting the joints, the pain centred in the nerve and radiated from it. The usual plan of treatment was adopted without relief, but on excising the tumour the local and constitutional symptoms completely subsided. The growth was of a fibro-cartilaginous character.

Dr. HUDSON described a method of treating Gleet by means of Metal Bougies anointed with carbolic oil, iodoform and resin ointment, or iodide of sulphur ointment. The bougie was retained *in situ* for from twenty minutes to four hours, and passed at first every four days and afterwards weekly till a cure was effected. He had used the method in eighty-eight cases and more than fifty had been cured. He attributed the success to the long-continued application of the drug and the paralysing influence of the bougie on the urethral muscle.

Dr. ALLAN brought forward cases illustrative of the good effect of Ergot in allaying Cough. He had used it in fifty cases of various kinds, both by subcutaneous injection (Bonjean's system) and by the mouth. In a large proportion of cases the relief was very remarkable.

Dr. JACOB showed Microscopic Sections of Actinomyces or the "ray fungus" from the tongue of a cow. Also specimens of the Micrococcus Pneumoniæ, asserted by Friedländer and others to be the active agent in the production of acute pneumonia.

Reviews and Notices of Books.

Lectures delivered at the Royal College of Surgeons of England on some important points connected with the Surgery of the Urinary Organs. By Sir H. THOMPSON, F.R.C.S., M.B. Lond., Surgeon Extraordinary to H.M. the King of the Belgians, Professor of Surgery and Pathology to the Royal College of Surgeons, Consulting Surgeon to University College Hospital, &c. Students' Edition. London: J. and A. Churchill. 1884.

On Tumours of the Bladder; their Nature, Symptoms, and Surgical Treatment. Preceded by a consideration of the best Methods of Diagnosing all Forms of Vesical Disease, including Digital Exploration and its Results. By the same Author. With numerous Illustrations. London: J. and A. Churchill. 1884.

OUR readers have already been put in possession of tolerably full abstracts of Sir Henry Thompson's Lectures at the College of Surgeons, but the former of the two volumes whose titles head this notice contains them in full, and it is very valuable to all surgeons and practitioners, containing as it does the result of the author's large and in some instances unrivalled experience. The first lecture is an able defence of the operation of internal urethrotomy for all strictures of the urethra which do not respond to the simpler treatment of dilatation by bougies. Sir H. Thompson is a staunch advocate for using a urethrotome which cuts from behind forwards; and although many able and very experienced surgeons with strong reason advocate the alternative method, the opinion he gives from a very large experience is well worthy of the careful attention of all who would practise this operation. But the chief interest in the lectures undoubtedly centres in the discussion of the nature, diagnosis, and treatment of vesical tumours, and in the results of Sir Henry Thompson's "more than 800 cases" of stone in the bladder.

The Lectures on Vesical Tumours, together with one on the Diagnosis of Urinary Disease, have been published separately in the latter of the two books before us. This makes a useful volume, in which the reader will find the present state of our knowledge of this question, to which Sir Henry Thompson has contributed so largely, fully given. Beautiful coloured plates of the microscopical appearances of the different groups into which the tumours are separated, as shown by specimens prepared by Dr. Heneage Gibbes, are added in this separate edition of these lectures, and they greatly add to the value of the volume. Two facts stand out pre-eminently as results of the author's great experience in vesical calculus. One is the enormous advantage which has accrued from the general adoption of the "one-sitting" operation of lithotrity with which Professor Bigelow's name must ever be associated; and the other is the demonstration of the greater frequency of stone in the bladder in the latter third of life than at any earlier period. The value of the eight hundred calculi, with accurate notes of each case appended, which Sir Henry Thompson presented to the College of Surgeons, is difficult to estimate, and it will stand as an evidence not only of the experience and skill of this distinguished surgeon, but also of his patience and care. We are very glad that these lectures are published in a cheap form which puts them within the reach of everyone interested in the subjects discussed in them.

A Handbook of Ophthalmic Science and Practice. By HENRY E. JULER, F.R.C.S. London: Smith, Elder, and Co. 1884.

THE author of this work has presented his readers with a very complete and systematic treatise on diseases of the eye. Having regard to the light which the ophthalmoscope has thrown on some of the most important diseases of the eye, and that by its use the eye has been connected in clinical practice with the cerebro-spinal system of which it is itself a part, Mr. Juler has rightly devoted a not inconsiderable section to diseases of the fundus. And in this part, as indeed throughout the work, the value is much enhanced by excellent coloured illustrations of healthy and of pathological microscopical appearances. Under the head of "optic neuritis" a clear and succinct account is given of the various theories which have been advanced to explain its production. The author avows himself a supporter of what may be called the continuity of tissue theory. Much as can be adduced in favour of this view, it does not explain the occurrence of optic neuritis in connexion with intra-cerebral growths—growths often small and far distant from the eyeball, and in some cases situate on the same side of the brain as the optic neuritis,—nor does it account for its presence in such diseases as spinal myelitis and spinal caries, cases of which are recorded by Allbutt, Séguin, Dreschfeld, and others. Of late years much has been learnt by which errors of refraction can be ascertained and corrected, and Mr. Juler gives ample attention to this part of the subject; the "shadow test" is also explained, and is illustrated by woodcuts. The visual field and the use of the perimeter are treated of, and typical coloured charts are given showing the utility of the instrument in detecting various affections, such as glaucoma, pigmentary retinitis, hemiopia, &c. The significance of defective colour-vision in relation to cerebral and spinal affections is also considered, and Mr. W. Adams Frost contributes an excellent article on colour-vision and its defects. The anatomical changes in glaucoma are well explained in the text and by means of coloured plates, and the various views as to its method of causation discussed. Mr. Juler rightly insists on the necessity of early operation in acute glaucoma, but does not allude to those cases sometimes met with in young women, where acute glaucoma, with marked high tension and loss of vision, have yielded and perfectly recovered under medical treatment. Such cases were recorded at a recent meeting of the British Medical Association, and are even said to yield very bad results if submitted to iridectomy. In another chapter the action of the various muscles of the eyeball is entered into, and their affections, paralytic and spasmodic, are dealt with. The causes of paralysis are discussed at some length, but no allusion is made to diphtheria until some pages further on, where it is casually mentioned under the head of "treatment." The subject of alterations in the size of the pupil is too briefly dealt with; myosis is dismissed in a few words, and no mention made of its occurrence in corneal and such affections; the subject of mydriasis is conspicuous by its absence. Throughout the work the latest and most approved methods of operation are pointed out, and rendered clear by means of woodcuts. A departure is made from the ordinary text-book by the introduction of coloured plates of certain affections of the anterior visible portion of the eye, such as pannus, pterygium, iritis, &c., and these will be of much service to the student. But to the text of this part of the work scarcely sufficient care has been given; in the symptomatology of iritis there is no allusion to the altered shape of the pupil; phlyctenular keratitis is dismissed with a brevity which the troublesome nature of the disease scarcely warrants, and its tendency to produce erosions of the cornea and permanent scars is not alluded to; gonorrhœal ophthalmia Mr. Juler attributes to "the introduction of the urethral discharge into the conjunctival sac," but the views of others, that it is in some cases of constitutional origin, have grounds of support sufficient to entitle them to notice. Molluscum contagiosum is more than mere "hypertrophy of a sebaceous follicle," having been shown to consist in actual proliferation and growth of the cells of the Malpighian layer of the skin. Pterygium, Mr. Juler writes, is "thought to be caused" by mechanical irritation,

Digitized by Google

but there is good evidence that it is frequently so produced; the author does not allude to its tendency to recur after removal. Lastly, "perivascularitis" is not a word which we wish to see in general use. But these blemishes are easily remediable in future editions, which the merits of the work will undoubtedly secure. The work is of larger size than most of the recent manuals on eye diseases, but many of these suffer from their condensation; and we can confidently recommend Mr. Juler's treatise to all who wish to acquire a sound knowledge of ophthalmic practice.

Dental Medicine: a Manual of Dental Materia Medica and Therapeutics for Practitioners and Students. By FERDINAND J. S. GORGAS, A.M., M.D., D.D.S. London: J. & A. Churchill.

ON opening this book haphazard, the first thing to strike the eye happened to be the somewhat dangerous advice for the treatment of alarming symptoms during anæsthesia of administering an inhalation of three to five drops of nitrite of amyl. This is scarcely a wise dose; for from one to three drops will very quickly produce most marked symptoms, and a dose of five drops inhaled would be attended with very great risk; indeed the author himself, a few pages further on, says very wisely that not more than three drops should ever be given to a patient unaccustomed to its use! For the rest of the book it may be said that it is a careful compilation of the various remedies employed topically in dental surgery, besides many which are recommended for internal use. It is satisfactory to find, however, that the medical uses are kept distinct from the dental uses of the various drugs; and in the latter those which are employed purely locally have the most stress laid upon them; though it would appear that dental surgeons are encouraged to prescribe for their patients in America to a greater extent than is common in this country. A very curious fact, which may also be looked upon as Transatlantic, is the entire omission of any mention of a very similar work by Mr. Stocken, the third edition of which was published in England in 1882, nearly two years before this appears! The dental student and practitioner will find either of these works serviceable as a text-book or for reference.

Brain: a Journal of Neurology. Part XXVII. October, 1884. London: Macmillan and Co.

THIS is a most interesting and readable number of a valuable periodical. Its cosmopolitan character is evidenced by the fact that the first two articles are contributed by Prof. Obersteiner of Vienna and Prof. Pitres of Bordeaux. The former writes upon the Cerebral Bloodvessels in Health and Disease, an important feature of which is the description of changes commonly recognised as morbid but met with under normal conditions. Dr. Pitres's article is on the Early Occurrence of Ankle Clonus in Hemiplegia, a symptom, he says, "of evil omen and an almost certain sign of an incurable paralysis." Dr. Bristowe contributes detailed accounts of cases of Tumour of the Corpus Callosum, and Ormerod on Muscular Atrophy after Measles in three members of a family. A tolerably extensive review of present knowledge upon Lesions of the Nervous System etiologically related to Cutaneous Disease is furnished by Dr. Radcliffe Crocker, and a theoretical discussion of the Nervous Discharge by Dr. C. Mercier. The number contains also Records of Clinical Cases by Drs. Handfield-Jones and Angel Money, and reviews and abstracts of recent literature.

QUARANTINE.—"The London Gazette" of Tuesday contains notifications that the Portuguese Government have reimposed five days' quarantine on arrivals from England, and that in consequence of the appearance of cholera in Paris quarantine measures by land and sea will be re-established in Spain in all their rigour.

New Inventions.

ST. DALMAS' "LEICESTER" SURGICAL DRESSINGS.

WE have had submitted to us samples of the St. Dalmas' "Leicester" Bandages, Adhesive Plaster, and Belladonna Swansdown. They are all very excellent. The bandage is woven with a soft selvedge on each side, is light, porous, elastic, and strong, and is greatly superior to calico. The adhesive plaster is spread on fine flesh-coloured cambric, is very flexible, thin, and readily adheres firmly but cleanly to the skin. The dressings are well worthy of trial.

SKIN GRAFTS FROM THE FROG.

To the Editor of THE LANCET.

SIR,—Finding that the treatment of granulating wounds by skin grafting is in country practice liable to fall into disuse through the unwillingness of patients to part with the little bit of skin necessary, I have lately been induced to try experiments with other substances as a substitute for human grafts. As the outcome of these experiments I find that bits of skin from a decapitated frog make grafts which admirably answer all purposes, forming a source of supply always at hand in the country, except during the winter months, being easily applied on account of their uniformity in thickness, and necessitating no pain to suffering humanity. The skin of a single frog yields grafts for an enormous extent of surface and preserves its vitality so long that, if the patient is at a distance, the portion of skin required can be carried by the surgeon in his pocket for an hour or more without injury provided it is wrapped up in gutta-percha, or other waterproof tissue, to prevent drying. As witnessed by me in three cases in which I employed this mode of treatment during the month of August, the frog grafts at first act as human grafts are known to do, but later on their behaviour is different. Thus, soon after being applied they disappear, but after a short time they appear again as a thin transparent film on the surface of the granulations, some of the films being raised in the centre and depressed at the edges, forming small conical elevations. At this period the skin at the edge of the wound takes on a very rapid growth, but, curiously enough, the grafts themselves grow but little, and some stop growing altogether, this being so different from what occurs in the case of human skin grafts. If the wound or ulcer is a large one, the rapidity of epidermal growth at the circumference also soon diminishes, unless stimulated afresh by a second application of grafts, so that often a series of settings of grafts is needed before the granulations are closed over with skin. Material for graft making, however, being so easily procurable, the large quantity of seedlings required offers no difficulty.

Apart from the surgical importance connected with the process, there is in it something of scientific interest as well. My friend and former teacher, Chief Professor Cleland of Glasgow, long ago suggested privately to me, and subsequently, I believe, in 1877 to his class, that in his opinion the process of healing by skin grafting forcibly demonstrated the correctness of Stricker's view of the existence of sexes in the tissues. The colonies of epithelial corpuscles at the edges of the ulcer remain quiescent through lack of one sexual element, which the grafts no sooner supply than reproduction rapidly sets in, fertilisation being probably brought about through the medium of the fluid which bathes the surface of the granulations. If the sexual theory accounts for the process, the skin that grows after the application of the frog grafts must be of the nature of a new breed, a cross between human and frog epidermal elements. The disproportionate growth between the frog grafts themselves and the circumferential epithelium in no way invalidates this supposition, seeing that a somewhat analogous condition exists amongst animals when families of the same species are crossed with one another, fertility being greatest on the side that tends to degeneration, and less on the side that aims at a higher development. I have not as yet studied the process histologically, but may be able to do so soon.

I am, Sir, yours truly,

WILLIAM ALLEN, M.D. M.Ch.

Leadgate, co. Durham, Oct. 1884

THE LANCET.

LONDON: SATURDAY, NOVEMBER 15, 1884.

WHEN the Royal Colleges of England lately presented their Conjoint Scheme for the approval of the Medical Council, and when that learned body so jauntily accorded its sanction to the scheme, probably neither the Colleges nor the Council had any conception of the surprise and dissatisfaction which the scheme would occasion. The scheme and its sanction by the Council are, indeed, a wonderful illustration of the fact that the great profession of medicine is little cared for and is hopelessly at the mercy of the medical corporations, who, by the legislation of 1858, were made masters of the situation, and who are likely to remain so, so long as Parliament continues to be incapable of doing the work of the nation. The English Colleges know best their own views and motives in the piece of trades unionism to which they have just committed themselves. But like other pieces of selfish and unwise trades unionism, it is likely to drive trade away and throw the business of educating and examining English students of medicine into the hands of the examining and teaching bodies of Scotland, or of the least of the medical corporations of England. This danger is now beginning to be perceived, and may, perhaps, be soon brought home to the respective Colleges which have so much to lose by wanton experiments. There is not much reliance to be placed on the Colleges. These two great bodies seem to be hopelessly led by some half dozen of their leading members, who seem to be unable to perceive the energy and the multiplication of rival bodies around them, but fancy that the institutions of Pall-mall and Lincoln's-inn have some inherent virtue which is to counterbalance all defects and faults. Take the College of Physicians, in which the Fellows have a considerable voice and responsibility. There is no proof that a dozen of the Fellows understood all the bearings and probable consequences of the Conjoint Scheme, and that in voting for it the majority of them were doing so independently and from conviction, and not from a blind kind of deference to the leaders of the College. At the beginning of the century the College of Physicians, in something like a spirit of contempt for general practitioners and their accomplishments, handed them over to the care of the Apothecaries' Society, or anybody else who chose to accept the duty of looking after them. It seems not impossible that the end of the century will witness the same [illegible] on the part of the College for the [illegible] of the general body of the profession and the same [illegible] between it and them. Of late years the College has been doing better. It had discovered that the licensing of general practitioners, in the full and complete sense, was one of its great and most honourable functions. It had been doing the work so well that increasing numbers sought its licence until the present year, when it is expected fully 200 entrants of the profession will take its double licence. Not only was the licence sought after, but the examination on which it was founded is spoken of with general respect; while the fees demanded are reasonable. In the midst of one-sided bodies granting *half* diplomas, here was one ancient body expressing in its diploma the *wholeness* of the Medical Act. Now all this is to be changed. The College is to enter into a contract with its sister College to refuse to grant its own licence and to discharge the functions assigned to it by charter. This sister College, now becoming, or about to become, wealthy beyond all expectations, might have been expected to take new and large views of its future relation to the profession. Instead of this, it has become a party to an extortionate, an imprudent, and probably an illegal conjoint scheme.

A correspondent last week, signing himself "A Scotch Graduate"—with perhaps a dash of pardonable national vanity—speaks of the disastrous effects of the competition of the Scotch Universities on London schools. We do not believe that the great schools of London are going to be eclipsed either by provincial schools, by the great school of Edinburgh, or by the other Scotch universities. The professors of these universities would be the first to recognise the enormous field for clinical research and study afforded by the hospitals of London, and not only afforded, but well used by the London teachers. At no previous time has the work of London physicians and surgeons and of London medical teachers stood higher in the estimation of Europe and America than it does to-day—for its thoroughness, its originality, its soundness, and its carefulness. Surely all this is not going to be lost to the cause of medical education in Great Britain. It only needs a better organisation of London schools, and the creation of a teaching university in London, to give to London advantages beyond all those cities which would presume to be her rivals. If metropolitan teachers would throw the same energy into the question that the Scotch Professors exhibit in fighting for their privileges, the cause would soon be won, and Parliament would be made to feel that the education of medical practitioners and the very progress of medicine itself were at stake. But if this energy is not soon forthcoming, it may be too late. Those responsible for medical education in London have hitherto given no hearty help to those who have been trying to procure medical legislation; they have acted as if the demand for legislation was work for agitators and not for them. They are beginning to open their eyes now, and to see how deep and grave is the need for some strong and independent authority to control the "battle of the shops." The absurd scheme to which the Colleges have committed themselves may do much to damage the London schools; and it cannot be too soon reconsidered by the Colleges and disowned by the teachers. We very much mistake if any folly on the part of the Royal Colleges will ever again drive men in great numbers to the Apothecaries' Society. That Society has had its day; and only by the grossest unwisdom on the part of the Royal Colleges could it have a new lease. The aspiration of men now is to be graduates in medicine, not apothecaries. It is an honorable ambition, and ought to be fairly within the reach of every good English student, as it is within that of every good Scotch student.

THE scheme for the reform of the Royal College of Surgeons of England, discussed and [illegible] general meeting of the Association of Fellows of the College

held on Saturday last, gives form and character to ideas and suggestions that have long filled many thoughtful minds, and embodies the principles for which this journal has contended for more than half a century. All that is now needed is an awakening of the whole of the Fellows and Members to the value of the recommendations proposed by the Association, and to the necessity of insisting on their speedy adoption. These are indispensable, not only in the political and academical interests of the Fellows and Members, but also in the best interests of the College itself. Though this necessity has been obvious to many persons within the Council of the College as well as without, no organisation has hitherto existed to give it a practical and workable shape. This organisation has at length arisen, and the effect of its operation may be seen in the report published in our columns on the 1st inst., and in the account of last Saturday's meeting which appears in our present issue. We have so often proposed recommendations identical with those contained in the scheme prepared by the Association of Fellows that further criticism or argument is unnecessary. It will be seen that the changes and alterations recommended to be incorporated in a new Charter embrace every department of the College and every phase of its action. The constitution of the Council, the mode of electing the President, the character of the Court and of the Board of Examiners, and the relations of Fellows and Members to the Council, are all fully considered, and definite proposals are submitted for their alteration and improvement. Suggestions are made by which the Fellows and Members may actively participate in the management of the College, and facilities are provided for affording them authoritative information of the transactions of the Council.

It is pleasing to note that, though the scheme has been prepared by the Association of Fellows, the Members are liberally provided for. We are, of course, aware that the Association of Members seems to think that the concessions made to Members might have been still greater. But this view cannot fairly be maintained. The Association of Fellows has recommended that Members shall be eligible to be members of the Board of Examiners in Anatomy and Physiology, and that they shall have a parity of voting power on all matters relating to the affairs and management of the College, which may be discussed at the annual general meeting. These provisions give to the Members a power and influence in the College to all intents and purposes commensurate with those enjoyed by the Fellows. Indeed, almost the only matter in which Members are not placed on a level of perfect equality with the Fellows is that of electing the Council and the President. In favour of the continuance of this disparity, at all events for the present, it may be urged that when the order of Fellows was instituted one of the alleged objects was to constitute a higher grade of Members who should enjoy electoral rights. Most of the existing Fellows have made great sacrifices and expended time and money to acquire these rights; and it should not be forgotten that it is open to any Member who wishes to participate in them to secure them by the same means. Every restriction and disability has been removed by which Members may have been prevented from becoming Fellows. All that now stands between a Member and the Fellowship is an examination which requires a sufficient knowledge of Anatomy and Surgery. It is surely no great hardship on the Members to demand from them those guarantees which most of the existing Fellows have had to furnish. To attempt to abolish them savours rather of Communism than of rational Republicanism. But even if it were allowed that no tenable argument can be advanced against the justice of the plea that Members should enjoy equal corporate rights with the Fellows, it is only reasonable to require that the Association of Members should show the practicability of conferring upon Members electoral rights. It will be soon enough to demand that these rights should be bestowed when the Association of Members has prepared a feasible plan of polling the votes of sixteen thousand persons. Meanwhile we would fain hope that the Association of Members will sink minor differences, and, keeping in the background all controversial and debatable matters, will lend all its force and influence to the Association of Fellows to secure those changes which are essential to the continued and permanent welfare of the College.

THE outbreak of cholera in Paris is a matter of European concern, and in this country especially the first feeling will be one of sympathy with our neighbours across the British Channel. The first deaths which were publicly recorded were three on November 3rd; during the next three days they varied between eight and ten; on the 8th there was a rapid increase to thirty-three, and since then a continuous rise has gone on, the mortality on the 10th instant having reached ninety-eight. No explanation is given as to the precise manner in which the disease commenced, but in view of the occasional recurrence of attacks in the south of France, and of the spread of the infection to Nantes and other places in the north, it is but too evident that the ordinary channels of communication have for a long time past amply sufficed to bring about a diffusion which, until a few days since, it was hoped had been averted. It is, indeed, stated that cholera has been in Paris ever since June, a statement which is probably founded on the occurrence of cases of the sporadic affection such as are met with in all large centres of population during the autumn months. Had the disease been genuine cholera it is difficult to understand why it made no material headway when so many circumstances, meteorological and other, were favourable to its spread. But, on the other hand, it is quite possible that scattered cases had occurred before the disease was officially recognised on November 3rd.

It is, however, the future that most concerns us at the present moment; and attention is largely centred on the circumstances which are in prospect both for Paris and for this country. As regards Paris, it is satisfactory to note that the later epidemics of cholera from which that city has suffered have shown a diminishing mortality. To compare only the last two outbreaks. During 1865 cholera broke out in June at Marseilles; thirty-six departments became infected. The disease reached Paris on September 18th, and by the end of the year it had caused 6441 deaths. The disease did not die out during the winter; indeed, according to the late Mr. NETTEN RADCLIFFE, eleven departments were newly attacked between November 3rd and December 26th; one, in which the first case occurred as late as December 13th, exhibiting a mortality of 132 before the expiration of

Digitized by Google

the year. In Paris occasional cases recurred month by month until July, 1866, when the disease again became epidemic, and remained so for four months, after which it gradually died out. The next outbreak was in 1873, when the disease reached Paris on September 5th. On this occasion it continued till December, but it then became finally extinguished. It will thus be seen that whilst too much trust cannot be placed on the mere advent of cold weather to stay the progress of cholera in Paris, yet there are grounds for believing that such sanitary advances as were made between 1865 and 1873 held an important place in lessening the extent and duration of the latter epidemic.

As regards this country, we find ourselves for the first time during the epidemic of 1884 in direct and daily communication with an affected city, and in view of the extent of the passenger traffic between the French and our own capital, and of the rapidity with which the journey can now be made, it is evident that we are open to the importation of the disease to a degree which has hitherto not been possible. Any attempt at quarantine could serve no useful end, for even the *reductio ad absurdum* which the process would bring about within the first forty-eight hours is hardly needed for any educational purposes as regards our own countrymen; and even a rigid system of inspection at such ports as Dover and Folkestone would almost certainly fail in detecting incipient attacks and patients passing through the period of incubation. Every sanitary district in England must, therefore, trust to its own resources; and we believe it is mainly, in so far as the authorities have come to see that under the circumstances of this country the Government cannot afford any useful protection by quarantine measures, that their respective districts will be found to have been prepared against invasion by cholera. It is essentially a local, and not an imperial, effort that is needed under existing circumstances; and, above all things, it behoves authorities to be prepared in advance with means for the immediate isolation of any imported cases, and to proceed with the utmost haste in removing from amongst the inhabitants of their districts all conditions favourable to the contamination of water and air. The need for isolation in hospital is the greater because treatment at home tends to the discharge of infected evacuations into sewers, cesspools, and privy pits, and to the diffusion of the poison by means of drain air and polluted wells; and as regards conditions leading to nuisance, whether by reason of faulty drains or accumulations of refuse, it should be a rule to regard filth in any form as affording the most favourable nidus for the development and diffusion of the cholera contagium. The infection may not reach us this year, but any expenses incurred in order to ward it off will, as pointed out by Dr. BUCHANAN in his official Memorandum on Cholera, not be thrown away; on the contrary, it will be an expenditure tending to the removal of the costly burden which infectious disease so often imposes on authorities who have disregarded the advice to keep their districts in a wholesome and cleanly state.

THE outbreak of cholera in Paris can only surprise those who are unacquainted with the sanitary condition of that city. There has been no lack of talk concerning sanitary measures, but no important improvement has been the result. The worst quarters of Paris remain much in the same condition as in 1882, when typhoid fever, always endemic, assumed the proportions of a formidable epidemic. In vain have Dr. DUMESNIL and the other members of the Commission on Unwholesome Dwellings protested against the insanitary character of the lodgings crowded by the poorer sections of the community. Nothing has been done. Closets remain not merely untrapped—there are hardly any closets in Paris, either in the wealthy or the poor quarters, that possess traps,—but they have no valves provided. The closet in many dwellings is merely a round hole in the floor, communicating with a huge ten- or twelve-inch iron pipe, that goes right down into the cesspool. The cesspools, of which there are 80,000 in Paris, are, it is true, ventilated by a pipe taken up to the roof of the houses. But there is no inlet ventilation provided; and consequently, as the soil pipe is warmer, it follows that the air must frequently, if not generally, descend the ventilating pipe, pass through the cesspool, to travel up the soil pipes into the houses. In a large number of houses the cesspool has been replaced by a metallic tub, which, while it retains the solids, allows the liquids to escape into the sewers. Thus the sewers are contaminated, though, according to the French theory, they should not receive anything worse than rain water and kitchen water. As a matter of fact, the water they contain is so foul that it frequently kills the fish in the Seine. Paris therefore, in spite of its cesspools, is exposed to all the dangers that arise from sewers. Nor is this all. As the sewers were not built for the purpose of carrying away the entire drainage of the houses, but were supposed to receive only comparatively clean water, they were not ventilated or constructed with the same care as would otherwise have been displayed. The fall is often insufficient, no proper means of flushing are provided, and the deposits formed are so considerable that an army of 800 men are at work, cleaning and scraping and pushing the heavy material along. Dr. BROUARDEL has calculated that in some parts of Paris any heavy substances thrown into the sewers would take no less than six weeks to reach the outfall. In Paris, we believe, forty is the average number of inhabitants to each house; while in London the number does not amount to eight per house. In the poorer quarters of Paris there are houses containing no less than 200 inhabitants; and, though such houses generally possess two, if not three, cesspools, an epidemic quickly spreads from one tenement to the other. Even if these dwellings are in a street of reasonable width, the back of the houses are too often devoid of light and air. The space restricted by the encircling fortifications and the dearness of land probably account for these grave defects. Topographically, Paris lies as if in a basin surrounded by hills, and the circulation of air is perhaps not as constant or as thorough as might be desired in times of epidemic; while above the gay city remains, suspended like a pall, a cloud of foul emanations from the 80,000 cesspools that vomit their gases over the roofs of the houses. As not more than 70,000 cesspools are cleared in the course of a year, it follows that these receptacles are only cleansed at very long intervals, and are therefore a constant source of danger to the population. Nor are the environs of Paris free from grave sanitary defects, for here are situated innumerable unwholesome industries, and notably the tanks of Bondy, where the

Digitized by Google

contents of the Paris cesspools are emptied in the open air. The nuisance that this occasions has been felt throughout the neighbourhood, and has led to many energetic but as yet vain protestations.

Greater, however, than all these defects is the uncertain character of the Paris water-supply. There are two exceptionally pure sources. The little river Vanne in the department of the Yonne has been brought to Paris by an aqueduct a hundred and five miles long, and is supposed to supply 110,000 cubic metres of water per day, while the Dhuis, a similar stream brought from a distance of seventy-four miles, yields about 20,000 metres per day. So long as these waters are drunk it would be difficult to find any cause of complaint. Unfortunately this provision occasionally runs short; then the authorities, without issuing any sort of warning, supply through the same pipes the dilute sewage water of the Seine or the Ourcq canal. Thus, though as a rule Parisians drink exceptionally good water, they at times unconsciously imbibe water which all authorities agree in condemning as foul and that is generally only used for washing the streets and flushing the sewers. The amount of pure water arriving daily in Paris is sufficient for drinking purposes if care were taken that it should not be used in other ways. On the other hand, the supply from the Seine of water for flushing drains and washing streets is practically unlimited, and new pumps for this purpose have been recently set up at Ivry, which can add 85,000 cubic metres to the former supply. If this dual supply were carried into the houses as well as into the streets, there would be an abundance for drinking purposes, and for the flushing, where practicable, of house drains. At present it only exists in the street; and, in the one pipe supplying the house, the pure water and the foul water are alternately turned on. Outbreaks of typhoid fever in certain streets have been traced to this cause, the dates of the cases corresponding with the time when the water was altered. A town suffering from all these disadvantages cannot be otherwise than accessible to the importation of epidemic diseases. This is not merely a question of cholera. The zymotic death-rate, especially with respect to typhoid fever and diphtheria, has been steadily increasing of late years. Surely measures can be taken at once to prevent the recurrence of such lamentable consequences. The water-supply of Paris cannot be increased in time to mitigate the present outbreak, but it can be better distributed. Nor can the sewers of Paris be rebuilt, the cesspools abolished, and a new system of drainage instituted, at a moment's notice; but a great deal can be done within the houses, to disinfect the soil pipes, ventilate the closets, and so close the various apertures as to prevent the filtration of foul gases through the dwelling rooms. We are glad to note that the Municipal Council has voted funds for such purposes, and trust that prompt and vigorous measures will at once be taken.

WE had hoped that long before this the personal bickering caused by the Report of Dr. CRICHTON BROWNE and the commentary thereupon by Mr. FITCH would have subsided, but the hope has not been realised. There is still manifest a strong desire to oppose the reforms suggested by Dr. CRICHTON BROWNE, and we regret to find at least one member of our profession, with purely negative opinions, throwing the weight of his influence on the other side. Members of the medical profession who support Dr. CRICHTON BROWNE'S allegation of over-pressure have not been so successful as Mr. CHARLES ROBERTS, F.R.C.S., in obtaining an extended publicity for their protests, and therefore so far as *the* lay journal is concerned, the evidence is one-sided and the case less strong than it might be in favour of reform. Mr. MUNDELLA'S play with the question would be amusing if it were less mischievous. When the Vice-President of the Council suggests as a consolation to those who complain of the injury wrought by brain-worrying and forcing that "there is a general sense of responsibility on the part of school-boards, school managers, and Her Majesty's inspectors as to the discharge of their duties in this respect," the position is absolutely grotesque. Imagine for one moment the probable effect of "a sense of responsibility" on the mind of an official person like Mr. FITCH! Surely Mr. MUNDELLA has of late lost his hold on common sense. He is disappointing his friends and losing confidence on all sides, and particularly in this matter of over-pressure has he struck a great blow at the confidence our profession has desired and honestly endeavoured to repose in him.

Again we protest — and with some means of judging, it will be admitted — that the voice of the profession is almost unanimous in acclaiming the justice and wisdom of Dr. CRICHTON BROWNE'S inquiry and report. The opposition—in so far as there can be said to be any—is the outcome of jealousy or inattention to the facts. If those members of our body who possess any special acquaintance with the subject of brain-training and development were interrogated individually they would, we are assured, be found in accord on the main facts. There *is* over-pressure, and its effects are already becoming evident in the prevalence of "nervousness" and nerve-troubles among children of an age and of a class which have not hitherto been notably affected with these ills. There will be worse consequences to deplore in the next generation than in this if the brains of growing, underfed, and worried children are to be forced at the caprice of *doctrinaire* educators, who know little of the children of the poor, and nothing—effective at least—about the physiology of the organ they are trying to cultivate. We do not for an instant doubt that it would be quite possible for the Education Department to accumulate opinions directly contradictory to that which we have expressed, and which we unhesitatingly affirm to be the opinion of the profession. It is always easy—too easy a great deal—to secure medical evidence on either side of a "case." Nevertheless, without quoting the old adage which insists on the greatness of truth and its final triumph, we are firmly persuaded that the upshot of all this controversy must, sooner or later, be a reconstruction of the educational system evolved by library philosophers, and unfortunately too recklessly applied and ruthlessly enforced by optimist administrators.

Brain-pressure without brain-feeding is a perfectly infatuated policy. The cerebral organism may not in all, but must in many, instances be permanently injured, because exhausted at the precise moment when healthy nutrition—that is, nutrition naturally promoted by, and proportioned to, healthy exercise—is essential to the integrity of the growing brain. Just as the muscular system of a two-year

Digitized by Google

old colt is ruined for life if its strength be too severely taxed, so the brain of a growing child will be irreparably injured if it be overworked, particularly when it is underfed. We are, in truth, much less concerned with the small increase of mortality which has occurred as a result of over-pressure than with the mind-weakening which is becoming evident among young children and the prevalence of "nervous" cases in a class of the population which has heretofore been especially free from this affection. Nor is this all. Nothing is more painfully apparent to the student of sociology than that this excessive or ill-timed education of the masses is already showing a tendency to deprave the moral character in a direction which it is most important in the interests of the race to protect. We cannot speak too plainly on this subject in the interests of public morality. We have grounds for believing that certain well-known depravities which progress *pari passu* with cerebral exhaustion are on the increase among those overworked children. Physiologists do not need to have this connexion of cause and effect expounded to them. The *fact*—for such it unhappily is—may be accepted, and it should have at least as much weight in this controversy as will suffice to enforce the need of looking below the surface, and pushing the inquiry much further than it has yet been carried. Dr. CRICHTON BROWNE has gone far, but others have gone still farther, and instead of being hoodwinked by the well-meaning but officially blinded executive of his department, the Vice-President would do wisely to institute a searching scrutiny before it is too late. We repeat, Dr. CRICHTON BROWNE'S protest has the support of the medical profession, and, as a body, we distinctly endorse what he has said.

DR. KOCH has broken the silence which he had maintained during the promulgation of various statements as to the comma bacillus and its etiological relationship to cholera, and in the last issue of the *Deutsche Medicinische Wochenschrift* he writes explicitly upon these subjects, adhering as strenuously as ever to his original belief in the specific character of this bacillus. Referring our readers to the article itself for the full argument, we may here present its salient points. In the first place, he points out that morphological similarity is not the same thing as actual identity, when dealing with bacterial organisms. Some, such as the spirochæte of relapsing fever, do possess unmistakable and peculiar morphological characters, but in the case of a large number the possession of other properties is needed to make a distinction. Thus the tubercle bacillus is recognised largely by its special staining reactions. But the best method of differentiation is that which is based upon the behaviour of the bacteria in cultures, under varying conditions of media and temperature, their power of spore production and their pathogenic qualities. It is becoming more necessary to study these organisms in all these respects before concluding as to identity or difference. The cholera bacilli have many points in common with other micro-organisms, resembling in their potato cultures the bacilli of glanders, and, in the slowness with which their growth causes liquefaction of gelatine, many other bacilli; and morphologically there are similar forms. But when all their properties are taken into account, the bacilli of cholera remain distinct from all others. Dr. KOCH complains of being misunderstood by many in his contention for the specificity of the comma bacillus, which if disproved would of course render it impossible to utilise its detection as a means of diagnosis in a doubtful case, and set at naught the indication thereby derived for the adoption of prophylactic measures. He maintains that many of those who have disputed the alleged specificity have done so from incomplete observation, not sufficiently appreciating all the methods employed, or being imperfectly versed in these methods. Since the Conference in July, when he described in detail the characters of these bacilli, he has received specimens from many quarters purporting to contain these organisms; but in not a single instance was he able to verify the fact. As an instance, he mentions specimens of curved bacilli and spirilla from cholera nostras, sent by Dr. KLAMANN of Luckenwalde; but neither Dr. KOCH nor his colleagues could detect any resemblance between them and the comma bacillus. He then proceeds to confute the statements made by LEWIS in THE LANCET of September 20th to the effect that curved bacilli closely resembling the bacillus of cholera occur in the buccal secretions. This, Dr. KOCH says, is no new observation; it has been known for years, but these buccal bacilli in gelatine cultures behave quite differently from the cholera bacillus; they are moreover larger, more slender, and less blunted at their extremities. If Dr. LEWIS had only taken pains to cultivate them in gelatine, he would have found that, unlike the cholera bacillus, they do not grow in a feebly alkaline peptone gelatine. Passing to the alleged discovery of the comma bacillus in cholera nostras by FINKLER and PRIOR, he alleges that these observers did not pursue the well-established principle of isolating the bacterial forms in their cultivation experiments, and consequently in their specimens many different kinds of bacteria can be detected. Four of these varieties were differentiated by KOCH—one not liquefying gelatine, and producing a green colour on cultivation; another, a short bacillus, not liquefying gelatine; a third form, which did liquefy the medium; and a fourth, slightly curved in shape, and also having this last-mentioned property. This last-named form alone bears any resemblance to the comma bacillus, and that only in the dried and stained specimens. As to its reactions, it grows more rapidly in gelatine and on potato than does the cholera bacillus; the colonies it forms in gelatine are rounded and finely granular, and it speedily causes the liquefaction of all the gelatine; in all of which respects, as well as in the effect on its growth of temperature, it differs notably from the comma bacillus. Dr. KOCH has lately had opportunities of examining the dejecta and intestinal contents in three cases of cholera nostras, two of which were fatal, but no comma bacilli were present. He also examined with a like result a case of arsenical poisoning, fatal in ten hours with vomiting, purging, and collapse, just as in a case of cholera; numerous bacteria were found in the watery stools, but not a single comma bacillus. And although at the Institute there have lately been made hundreds of examinations of normal and morbid stools, the latter from all classes of diarrhœal disorder, micro-organisms resembling the cholera bacilli have never been found. He has not therefore met with any evidence to disprove his contention that the comma bacillus is specific, belonging exclusively to Asiatic cholera;

Digitized by Google

and until the arguments he has adduced can be upset, the diagnostic value of the bacillus must, he thinks, be recognised. There is also hope that the obstacle in the way of accepting this doctrine, arising from the failure to transmit the disease to animals, may be overcome. For RIETSCH and NICATI at Marseilles succeeded in producing cholera in dogs and guinea-pigs by injecting pure cultures of the bacilli into the duodenum. In their first experiments they performed a preliminary ligature of the common bile-duct, but this was found later to be unnecessary. KOCH has repeated this experiment, employing for the purpose a highly attenuated culture of the bacillus, and not tying the bile-duct. With few exceptions the animals died in from twelve hours to three days with choleraic symptoms, and the duodenum presented reddening of the mucous membrane, and contained watery contents, colourless, reddish, or flaky, and in them were found large numbers of the bacilli in a "pure culture." The minute quantity of material used in the experiment precludes the idea that the effects were due to the simultaneous introduction of a chemical virus; and he concludes by believing that a further prosecution of this line of research will establish the truth of the doctrine he enunciates.

DR. DE HAVILLAND HALL has done good service by calling the attention of the Medical Society of London to the subject of surgical scarlet fever. His paper was a careful account of a typical case observed by himself in a patient recently submitted to operation in the Westminster Hospital, and an able review of the literature of the question. There are many points of great interest connected with this malady. The first and most important is as to the nature of the affection, whether it is scarlatina or some disease allied to it but separate from it and owning a distinct cause. On this point there seems to be now no room for doubt. The affection is veritable scarlatina which runs the ordinary course of that malady, or rather may run any of the varied courses the many forms of that exanthem present, and, what is most important, it has all the infectiveness of the ordinary disease, and may convey it to unprotected persons who are not the subjects of wounds or surgical diseases. This being so, the question arises, What connexion has the disease with operation wounds? It cannot for a moment be held that a wound is the efficient cause or generator of the scarlet fever poison, but it is quite in harmony with our knowledge of this disease to believe that the existence of a wound may so act upon a person's system as to make it a fit nidus for the development of the "germs" of that disease acquired from some other source. It is a very common observation that of several individuals equally exposed to the scarlatina poison only some will suffer from the disease. Again, a person may be exposed to the scarlet fever infection many times with impunity and yet eventually be attacked. The most striking instance of all is that of the pregnant woman, who passes scathless through infection during the period of gestation but at once falls a victim to it after confinement. It is, then, a familiar fact that all persons, and the same persons at all times, are not alike prone to suffer when exposed to the infection of scarlet fever, and it is therefore fully in harmony with this view to hold that a wound may predispose to the development of scarlatina, or may remove the protection against the disease which the individual previously possessed. The fact that the other exanthemata are not thus associated with wounds by no means invalidates this argument. We do not yet know what the particular state of the system is which renders it a suitable soil for the development of these specific poisons, and there is no evidence to show that it is the same for all. Indeed, cases are not unfrequently met with of individuals or families who suffer with particular readiness and severity from some one or other of the acute specific diseases, and show no similar special proclivity to suffer from any of the others; or, indeed, they may seem to be specially protected from some one or other of them. The discussion that followed upon Dr. HALL'S paper brought out the fact that other erythematous rashes besides that of scarlet fever may follow upon a wound. This is a very important field for diagnosis, which demands the utmost care, for the distinctions between simple erythema, slight superficial erysipelas, and scarlet fever are not to be easily drawn, and it may be that there are other eruptions, more or less specific in nature, which may follow recent wounds, and which have not yet been classified, or even recognised. However this may be, it seems clear that surgeons should be on the look out to recognise scarlet fever in connexion with surgical operations and affections, and that they should at once take all the known precautions to prevent infection which are adopted in the more usual epidemic forms of the disease.

Annotations.

"Ne quid nimis."

INDIAN MEDICAL SERVICE.

WE observe with much satisfaction that measures have been taken to remove some, at least, of the grievances which have been the subject of complaint by the officers of the Indian Medical Service. The absurd, because incorrect and misleading, term "unemployed pay" is to be abolished, and that of "grade pay" substituted. This of itself would have been of little consequence, but an important modification has been at the same time introduced into the conditions under which this rate of pay is in future to be issued. Instead of being applicable to all officers not holding appointments which entitle them to charge-money, it will be confined to those who are in receipt of staff salary in addition to their pay; and it has also been decided "to place all surgeons of the Indian Service not holding executive charge on precisely the same footing in respect of pay as surgeons of the Army or British Medical Department similarly situated." This does away with one of the grievances which we have always thought pressed most unjustly upon the officers of the Indian Service. There are still two others to the removal of which we think the attention of the authorities ought to be directed. The first is the rule by which officers have "to pay their way to all appointments in which they draw higher pay." In some cases this operates most unfairly, the expense incurred exceeding the benefit derived by the officer. Where an exchange is effected for the convenience of officers at their own request, such a rule is quite fair; but where the appointment is made in the interests of the service, the necessary expense should clearly be borne by the public. The other grievance which, in our opinion, deserves consideration is the issue of what is termed "officiating pay" to medical officers put in charge of native regiments, but not permanently appointed to them. So long as the system is kept up of paying for

Digitized by Google

certain duties by allowances in addition to grade pay, it appears but fair that the officer who discharges the duty should receive the allowance; if any distinction should be made, it ought rather to be in the way of giving a higher rate to the officer who is merely temporarily employed. The rule in the Army Medical Service is that the officer in charge shall draw the "charge pay" whether he fills the post temporarily or permanently, and we do not see why a similar rule should not hold in the Indian Service. It may be presumed that the allowance is made with reference to the amount of work to be done and of responsibility to be incurred, and it seems somewhat anomalous that it should vary with the permanent or temporary tenure of the appointment, which creates no difference in these two conditions. We are glad to see that Mr. Cross, in announcing the change as regards "grade pay," stated that the number of "unemployed" medical officers had been reduced to two in the Bengal Presidency; the numbers in Madras and Bombay had not been received. While we congratulate the Indian authorities on the manner in which they have redeemed their promise to remedy as far as possible this grievance, we trust they will not rest satisfied till they have been equally successful in removing the still existing causes of discontent to which we have, on previous occasions as well as now called attention.

THE PROFESSION IN PARLIAMENT.

IN his delightful "Memoirs of an ex-Minister" Lord Malmesbury records a visit of Dr. Fergusson — the late Dr. Robert Fergusson, we presume, who is so honourably associated with Sir Walter Scott's declining years,—and reports the Doctor's opinion on the state of parties and the political outlook of the day. "I fear he is right," says Lord Malmesbury (and right he unquestionably was, as all who remember the agitated spring of 1857 can attest), "for," adds his Lordship, "nobody is a better judge of public feeling than a doctor who is constantly seeing all kinds of people." The biographies and the published diaries of English statesmen abound with similar acknowledgments of the sagacity of their medical advisers in probing and forecasting affairs, and yet the English Parliament is conspicuous among the legislative bodies of Europe for the almost absolute exclusion of physicians and surgeons from its membership. Our representative system is on the eve of vital transformations, the aim of which is to render Parliament a just and efficacious reflex of the collective interests of the community, and redistribution will assert itself not in electoral districts only or in the sense of the traditional wire-puller. If fewer barristers and financiers are to command the suffrages of future constituencies, is it unreasonable to expect that the seats they vacate will be filled by representatives trained in the study and application of other laws than those of contract and capital—of that law particularly which controls the highest and widest of all interests, the *salus populi*? Certainly, if such a consummation were brought about, no statesman ought to be better pleased than the genial ex-Minister whose Memoirs are on everybody's lips, and whose great chief once inscribed upon his banner: "Sanitas sanitatum, omnia Sanitas!"

INTERNATIONAL MEDICAL CONGRESS.

AN influential committee has been formed in Stockholm under Professor Axel Key's presidency to carry on the work of collective investigation in Sweden in connexion with the International Committee. A similar committee has been formed at Professor Runeberg's instance in Finland. The recommendations of the subcommittee as to the lines of inquiry to be pursued are at present under the consideration of the International Committee.

THE PUBLIC HEALTH IN THE PAST SUMMER.

THE Registrar-General's quarterly return, recently issued, shows the result of the past hot summer upon the public health. The mean temperature of the three months ending September last was 3·0° F. above the average in 113 years, and has during that period only been equalled or exceeded six times—in 1779, 1780, 1818, 1857, 1859, and in 1868. The summer of 1868 was the hottest on record. When it is also borne in mind that the rainfall was only four inches and a half, and three inches below the average, it will not be surprising to find that the meteorological conditions of the past summer were not favourable to health. The annual death-rate in England and Wales, which had averaged only 17·1 per 1000 in the three cool summer quarters of 1881-82-83, rose to 19·7 in the corresponding quarter of this year; this rate was, however, exceeded in four of the seven summer quarters of 1874-80, and was 4·0 below the rate that prevailed in the unprecedentedly hot summer of 1868. Compared with the mean rates in the three preceding healthy summer quarters, the mortality last quarter showed an increase of 16 per cent. in the principally urban, and 13 per cent. in the mainly rural population. Mortality in the summer quarter is, to a great extent, governed by the fatality of diarrhœa, principally infantile, which caused 18,630 deaths last quarter, and an annual rate of 2·72 per 1000, the average rate in the ten preceding summer quarters being only 1·91. Hot summers are specially fatal to infant life; and the rate of infant mortality last quarter, measured by the proportion of deaths under one year to births, was 191 per 1000, exceeding by 32 the average proportion in the summer quarters of the ten years 1874-83. It is satisfactory to note that infant mortality was lower last quarter than in the more moderately hot summer of 1880. Notwithstanding the excess in the death-rate last quarter, the annual rate of English mortality during the nine months ending September did not exceed 19·4, and was 1·3 below the mean rate in the corresponding periods of the last ten years, and there is every reason to conclude that the national death-rate of 1884 will scarcely, if at all, exceed the low rates in the three preceding years, giving the strongest ground for hope that the remarkable reduction in the rates of mortality recorded since the beginning of 1881 represent a corresponding and permanent improvement in the public health.

SENILE GANGRENE.

AT the Medical Society of London on Monday last Mr. Rogers Harrison showed a remarkable specimen of a mummified foot and leg, separated by spontaneous amputation. The patient was a gentleman in his seventy-ninth year, who was suddenly seized with severe pain in his foot, which became cold and benumbed, and then completely mummified. After several weeks the member was detached by the natural process of separation a little below the knee, and the patient recovered with an excellent stump. The case is remarkable for the great height to which the gangrene extended, as well as for the successful conduct of it by unaided nature. In a discussion upon the treatment of senile gangrene raised by a paper of Mr. Jonathan Hutchinson's at the Medical and Chirurgical Society some months ago, stress was justly laid upon the fact that different cases of this affection present varied features and run a different course. Mr. Rogers Harrison's was a case of true dry, or arterial, gangrene, due in all probability to a blocking of the popliteal artery just at its bifurcation. There was no disease of the heart or aneurysm to be detected, and therefore the affection was probably a thrombosis caused by calcification of the artery, and most probably, the clotting, having started in the popliteal trunk, spread down the two tibial trunks, and so precluded any sufficient establishment of an anastomotic circulation. It was a case of primary gangrene, the death

Digitized by Google

of the part being directly due to a want of blood, and not dependent in any degree upon inflammation. The treatment adopted was undoubtedly the wisest possible, and was brilliantly justified by the result. Such a mummified member was not a source of danger to the patient from blood-poisoning, and there was at no time any tendency for the gangrene to spread, so that there was no justification for amputation, which would have been attended with grave risk to a man of this advanced age, suffering as he was from chronic pulmonary disease. Dr. Hare, who had several times seen the patient previous to the occurrence of the gangrene, laid stress upon the little evidence of atheroma in the large vessels. This, however, is quite consistent with advanced calcareous disease of the smaller arteries.

THE DEATH OF MR. FAWCETT.

THE death of Mr. Fawcett, humanly speaking, is one of the saddest events which could have occurred, and deprives the State of one of its most faithful and promising servants, and society of one of its most remarkable men. The existence of such a man—blind, yet "leading the blind," and showing them the possibilities of life under conditions of blindness, and full of light and hope for humanity, as well as of political wisdom and strength—was a national blessing and credit, of which the country might have hoped for a continuance for years to come. Many men with sight might have been better spared. We have little to add to what has been already made public of the nature of his illness. It was of a pneumonic and pleuritic character, and accomplished its deadly work with much quickness and, we regret to say, with much pain, the pleura covering the diaphragm being much affected. It is easy to speculate on the probable causes of such a disaster to a man of fifty-one, whose father and mother, by the way, are yet alive. The season has been favourable to such attacks. His previous illness did not lessen his liability to them, and we should probably not be far wrong in supposing that the worrying autumn session, added to his departmental labours, produced that fatigue which makes the system more vulnerable to the causes of catarrhal disease.

ISOLATION AT BRISTOL.

IT is not often that we find ourselves at variance with the veteran medical officer of health for the city of Bristol, but in the matter of the isolation of infectious diseases we are quite unable to understand the advice which he tenders, and it is evident from the comments in the local press that we are not alone in this matter. The whole system, as indicated by a letter which he, in his official capacity, has addressed to the *Bristol Mercury*, is evidently regarded by the sanitary authority from a point of view which we think to be faulty. Although from recent reports it appears that two hospitals exist, and although their value in enabling the city to crush out an outbreak "in the bud" is prominently brought forward, yet now, when the closure of the fever hospital is in question, Mr. Davies, instead of advocating the maintenance of a building to which first attacks could be removed, points out all the hindrances to isolation, explaining that he can only compel removal on a justice's order, that no one would be admitted unless payment is guaranteed in advance; and then he goes on to say that typhus can be safely isolated in a private house, he having done so in his own house successfully. With all due deference to Mr. Davies's high merits as a sanitary official, we would urge that the tendency of his letter is retrograde in the extreme. In the first place, Bristol, whilst keeping open a hospital for the only infectious disease the spread of which can be prevented by other means than by isolation—namely, small-pox—never makes any attempt to "nip in the bud" the far more fatal scourge of scarlet fever, and now it would appear that typhus is to be relegated to private houses. Unfortunately, the people amongst whom this disease of dirt and overcrowding almost exclusively prevails have not such houses as Mr. Davies possesses. Then again, although the Public Health Act contains a clause as to compulsory removal, experience everywhere shows that the powers given as to this are rarely resorted to, and that thousands of cases of such diseases as scarlet fever are isolated without any reference to it; and this with nothing but benefit to the surrounding community. And further, though the same Act enables sanitary authorities to recover the cost of the maintenance of patients in isolation hospitals, yet it was certainly never anticipated that such authorities would make an undertaking as to payment an absolute condition of admission. The prime object of infectious hospitals is to prevent the spread of infection, and not to make such prevention dependent on recovering a small payment on behalf of the individual who assents to be isolated in the interests of the community. We wish that Bristol could see its way to follow in the path of many other sanitary districts which, having provided themselves with proper isolation hospitals, so use them as to protect to the utmost possible extent the public by whom and for whom they have been constructed.

TREATMENT OF MARSH FEVER BY SUBCUTANEOUS INJECTIONS OF CARBOLIC ACID.

DR. DIEULAFOY communicated to the Société Médicale des Hôpitaux of Paris, on the 10th ult., the history of a patient who since 1877 had had tertian fever three times, which had always been successfully treated by the administration of sulphate of quinine. The fever having returned last June, the patient came under the care of Dr. Dieulafoy, who on the first day injected subcutaneously two centigrammes and a half of carbolic acid dissolved in a hundred parts of water. The quantity was increased on the following days to five centigrammes, and to seven centigrammes on the days of apyrexia. Recovery was complete at the end of seventeen days. The patient had then absorbed eighty-four centigrammes of carbolic acid, without showing any signs of poisoning. In the subsequent discussion, Dr. Laveran reverted to the fact that carbolic acid injections had been employed against marsh fever so far back as 1869, with questionable success. He doubted the propriety of attempting to supplant so certain a remedy as sulphate of quinine. Dr. Huchard related the case of an Arab in whom quotidian attacks of fever, which had resisted all other remedies, yielded to bromide of potassium; and Dr. Labbé alluded to the good effects, too much overlooked, of arsenical medication in malarial poisoning.

ALLEGED DEATH FROM VACCINATION.

AN inquest was held on Friday, Oct. 31st, at the Clapton Park Tavern touching the death of an infant aged four months. From the evidence it appears that the deceased was found dead in bed by its mother's side. Dr. Aveling of Clapton was called in, and at the inquest he deposed that he had not the slightest doubt that the child had been suffocated through overlaying, but a majority of the jury, ignoring the expressed belief of Dr. Aveling, refused to return a verdict in accordance with it, though advised to do so by the coroner, Mr. Collier. Very wisely, as we think, the inquiry was adjourned for a post-mortem examination to be made. The jury, however, declined the assistance of the doctor nominated by the coroner, and demanded that the autopsy should be supervised by a gentleman of their own selection. After much bickering, it was eventually settled to ask Dr. Collins to officiate. This he did in the presence of Dr. Bristowe,

Digitized by Google

of St. Thomas's Hospital, and Drs. Aveling, White, and Millar. At the adjourned inquest Dr. Collins is reported to have said that death "could have arisen from three causes—asphyxia, convulsions, or blood poisoning; he thought convulsions." That the proximate cause of death was asphyxia there seemed no manner of doubt, but we contend that there was no evidence to show that it was due to convulsions. What were the facts as sworn to by the mother? The child appeared in good health when she retired with it to rest; in the morning she found it dead. We venture to say that had the child not been recently vaccinated no difference of opinion would have arisen as to the cause of death. That the mother of the infant was blameless is beyond question, but for all that we maintain the most reasonable explanation of the fatal event was, as so frequently happens, that the deceased was overlaid. Scarcely a week passes without the record of such a mishap; and it is notorious that it occurs apparently without a struggle, the insensibility of sleep passing quietly into that of asphyxia. In a case like the one under consideration, it is very essential that the facts should be read by the light of similar cases the nature of which is understood. Had convulsions been suddenly induced whilst the infant was awake and restless, in all probability the mother would have been aroused. It is not our purpose to deny that septic absorption can take place through the medium of a vaccination sore, but to insist, with all deference to those who had the responsibility of deciding upon the facts as disclosed at the inquest, that in this case there was no proof that it occurred. Speaking impartially, for we have only the well-being of the community at heart, we are compelled to come to the conclusion arrived at by Dr. Aveling, and, as a matter of justice, to protest against non-professional men assuming the function of skilled scientific witnesses by interpreting facts without the necessary knowledge for their elucidation. It was the *positive* opinion of the doctors against the *negative* opinion of the mother, and not the reverse, as a member of the jury seemed inclined to think. We do not cast the slightest imputation on the honour of the "twelve good men and true," nor question their *bona fides* in the matter of their inquiry, but we wish to point out that they are satisfying at once the dictates of their consciences and the requirements of the law when they content themselves with solving medical problems by the aid of medical testimony.

PULMONARY SURGERY.

AT the meeting of the Medical and Chirurgical Society on Tuesday last, Dr. Cayley made another contribution to the subject of "Pulmonary Surgery," which he has already so much advanced. The case he related was, like his two previous ones, an instance of localised gangrene of the lung, which was treated by the insertion of a drainage-tube into the sloughing cavity. The origin of the affection was unfortunately malignant disease of the œsophagus and stomach, with perforation into the lung, from which the patient died a few days after the operation. But looking at it in the light simply of a gangrenous cavity of the lung, treated surgically, the case is important and distinctly encouraging in its result. It shows that these patches of gangrene can be sufficiently well localised to admit of surgical treatment, and that the operation of opening such cavities is devoid of serious risk and attended with marked relief to the very distressing symptoms of this affection. But the case also illustrates the difficulty the surgeon finds in exactly hitting the cavity, even when the physician has localised it as accurately as possible; for Mr. Gould, who performed the operation, failed to reach the cavity on the first attempt, although he punctured the lung in several directions. This difficulty probably results from the different intensity in which the various physical signs produced in the gangrenous area are conducted to the surface of the chest. Solidification of the lung in a small patch over such a cavity may render the physical signs much more distinct there than just around where the lung is not solid, and so it may happen that the physical signs of the pulmonary gangrene are not most clear vertically over the sphacelus. The surgeon is then left in doubt as to the direction beneath the spot indicated on the walls of the chest in which to thrust his trocar; but in spite of this uncertainty this case, and also in particular Dr. Cayley's other cases, clearly indicate surgical interference and drainage to be the best means of treating localised pulmonary gangrene.

SIR MOSES MONTEFIORE.

NOW that Sir Moses Montefiore has achieved his century of existence, it is to be hoped that he may be permitted to spend the remainder of his days in quietness. The very celebration of his birthday and its accompaniments involved no small risk to life. The tension of hope and fear, the desire not to disappoint one's friends of such a notable event, must have been trying, and indeed were. Sir Moses, we have reason to believe, feels perceptibly not so strong as at the time of his previous birthday. He was very anxious lest he should not be well enough to present a chain of office to the first Mayor of Ramsgate. This he was able to do, and did well, but the previous anxiety joined to the labours of the two days of ceremony told on him much, and on the Wednesday following his birthday he was greatly prostrated. For ten days the improvement was very slow, but on Saturday and Sunday last it was distinctly marked. Sir Moses is quite free from any particular illness, and by reason of his fine constitution, the good care taken of him by his medical adviser and others, and the blessing of the benignant Providence which he has experienced so largely, there is ground for hope that his useful age may still be considerably prolonged. Touching the element of heredity in his longevity, we should be glad to see full particulars for a few generations back. His father died at so early an age as forty-four, his mother, we believe, at seventy-nine.

A QUESTIONABLE APPOINTMENT.

IT is certainly very unsatisfactory to find that the system of promotions and appointments in the Indian Medical Service is worked in a manner which cannot fail to create a feeling of dissatisfaction among its officers. It may be in the recollection of some of our readers that in the early part of last year a junior brigade surgeon was selected for promotion to the rank of deputy surgeon-general and was immediately nominated to the charge of the North-West Provinces and Oudh, with the local rank of Surgeon-General. As we pointed out at the time (THE LANCET, Feb. 3rd, 1883), such an appointment, although within the conditions of the Royal Warrant, was at variance with its spirit and contrary to the principles of justice by which such proceedings should be regulated. It is, therefore, with much regret that we learn from the Indian papers that this unjust and illegal course has again been followed. Dr. Dallas, an brigade surgeon, has been selected for promotion to deputy surgeon-general and has been nominated to the charge of the North-West Provinces and Oudh, with the rank of surgeon-general, over the heads of a considerable number of medical officers senior to him in rank. Dr. Dallas is, we believe, a very able officer, and we have no doubt good reasons could be assigned for his selection for promotion, but we are curious to know on what grounds his advancement to the higher local rank, carrying with it increased pay, over the heads of can be justified. It is stated in a letter [illegible]

Digitized by Google

tary Gazette that Dr. Bellew, one of the officers thus unfairly superseded, addressed a memorial to the Lieutenant-Governor on the injustice thus done him, but that through some means the receipt of it was delayed until after the appointment had been made. We are unwilling to believe that this statement can be well founded, but, publicly advanced as it has been, it appears to call for inquiry. Mr. Cross has shown himself to be interested in the welfare of the Indian Medical Service, and we have no doubt that if this repetition of an act apparently so unjust as that involved in the appointment of Dr. Bellew as local surgeon-general is brought to his notice it will receive his careful consideration. Until an inquiry has been made by some competent and authorised person we refrain from imputing blame to any individual, but if no such step is taken there can be little doubt that a very unpleasant feeling will be aroused with regard to the administration of the department. We recommend the subject to the consideration of Sir Joseph Fayrer, who is the authority in this country by whom the interests of the service should be looked after, and on whom should devolve the responsibility of seeing that any act of apparent injustice is brought to the notice of the governing authorities.

THE DRAINAGE OF LONDON.

ALTHOUGH the evidence taken before the Royal Commission on Metropolitan Sewage Discharge is supposed to be kept secret, still there can be no doubt from the prominent way in which the scheme of Sir Joseph Bazalgette has been put forward in this journal that the Commissioners have practically decided upon recommending either that scheme or some altered modification of it. Roughly, it is to carry the sewage from Crossness under the river to the north shore, and to convey the whole volume to Thames Haven and there to discharge it in its *crude* state. So far as London is concerned, this will be an enormous benefit, but it is well not to forget the claims of other small places. Southend (the Brighton of the East-end) is within ten miles of the proposed outfall, and as for miles on either side of it there exist large flats and mudbanks, there can be little doubt that the deposition of crude sewage thereon must cause serious detriment to the prosperity of the place. The estimated rate to pay for the extension of the sewage works is but 1¾*d.* in the pound. Surely it is worth while to spend another farthing in precipitation, and save the possibility of ruining a very popular resort. It would be a serious blunder to benefit London by destroying Southend.

SCROFULA AND TUBERCLE.

FOR the most part experimental pathology has sided with the view that scrofula and tubercle are practically the products of one and the same disease. Clinical physicians frequently maintain the distinctive nature of these diseases. Some recent experiments made by M. Arloing would seem to give countenance to the opinion that scrofulosis and tuberculosis are not precisely similar morbid processes. It was found that subcutaneous inoculations from a caseous gland performed on a series of guinea-pigs and rabbits was followed by tuberculosis in the former animals, but for the most part the rabbits remained unaffected. When intra-peritoneal injections of the virus were carried out it was discovered that at the end of about a month all the guinea-pigs had died of tuberculosis, whilst none of the rabbits had suffered in any way. In this double set of experimental inoculations, caseous glands taken from the neck of a boy were employed as the material for inoculation. A third set of experiments, where inoculations were practised with fungoid material from the synovial membrane of joints affected with white swelling, both rabbits and guinea-pigs were simultaneously affected with tubercle. Again a fourth series was carried out with some matter taken from swollen cervical glands in a young woman who had no other symptoms of disease. A rabbit and a guinea-pig inoculated with this material died of general tuberculosis; and three weeks after the operation for removal of the cervical glands the young woman herself succumbed to acute tuberculosis.

EXHIBITIONS AND HOSPITALS.

IT is announced that an International Exhibition is to be held at the Alexandra Palace next year, commencing about March 31st. Exhibitions are very popular just now, and we hope that this one may be crowded every day of the six months during which it is to be open. Our enthusiasm on its behalf is evoked by the following paragraph in the prospectus:—"The administration have determined upon setting aside one-tenth of the entire receipts for admission for distribution amongst the various hospitals of the British metropolis, under the control and management of a committee for charitable purposes, of which Col. Sir Herbert Sandford, R.A., has been appointed chairman." The committee also includes, among others, the names of Sir Andrew Clark, Sir Henry Pitman, and Dr. George Johnson. We trust that the benevolent, kindly, and, as we believe, far-seeing policy adopted by the promotors of this Exhibition may result in a substantial addition to the funds of those institutions which, in the truest and best sense of the word, "entertain" the sick and wounded. Following the successful example set at South Kensington, the attractions of the exhibits will be supplemented by amusements, &c., and the building and grounds will be brilliantly illuminated by the electric light. In the interest of the hospitals, we trust that the executive, who by reason of their kindly thought deserve, will do everything to command, success.

THE BERLIN MEDICAL FACULTY AND PROFESSOR V. SCHWENINGER.

THE dissatisfaction at the arbitrary appointment of Dr. v. Schweninger to an extraordinary professorship of dermatology in the University of Berlin is growing, and has found expression in a protest from the medical faculty. This gentleman, hitherto unknown to fame, has the fortune of being "Leibarzt" to Prince Bismarck, and rumour says that it is owing to influence from this high quarter that the Minister of Education, Herr v. Gossler, made the nomination that is so distasteful to the faculty. Professor Virchow in the Chamber questioned the legality of this appointment, and also the conferring of the title "Professor" upon several "Privat-docents," which has recently been practised. Professor Virchow maintains that new professors cannot be appointed unless there are vacancies to be filled up. Dr. v. Schweninger has already entered upon his duties, and taken charge of the dermatological *clinique* at La Charité Hospital.

THE TRICYCLE UNION.

A SPECIAL general meeting of the members of the above-mentioned union was held on November 6th at the Westminster Palace Hotel. Dr. Richardson, the President, occupied the chair. In the course of his interesting and suggestive address we find that he assumed very much the same position that THE LANCET has taken up as regards the dangers attendant on the immoderate use of the tricycle, pointing out the ill effects likely to follow continued or excessive tension on the heart and lungs, and fixation of the body for long periods in a constrained position. He deprecated the custom of making an enjoyable and instructive mode of travelling a means for "sport" and sustenance for society journals. With his accustomed lucidity and happy

Digitized by Google

faculty of devising how the public may gain by physical and intellectual pursuits, he proposed a division of the union into artistic, antiquarian, geographical, and mechanical sections; that is to say, cyclists should use their machines as levers for the elevation of their minds, by travelling to the scenes where nature's stores are unrolled for the delight and profit of those who seek her guidance and teachings. In other words, Dr. Richardson would not have the whole nervous energy of an enthusiastic cyclist expended in the propelling of his body at so many miles per hour or through so many hours per day, but would divert a just proportion of that energy to the acquirement of useful knowledge. We sincerely hope that his advice will not go unheeded, but that his fellow-unionists will lay to heart and put into practice his words of wisdom.

LIGATURE OF THE RIGHT COMMON CAROTID AND INTERNAL JUGULAR VEIN.

AT the October meeting of the North-West Provinces and Oudh Branch of the British Medical Association, Surgeon Shirley Deakin, I.M.D., showed a Eurasian male patient, aged forty-two, on whom he had ligatured with carbolised gut the right common carotid and internal jugular vein two months before. The operations were performed at the time of the removal of a large, foul, fungating epithelial mass, which had sprung from some cervical glands, in which the disease had recurred after the removal of the right half of the tongue at a hospital in Calcutta, where a second operation was attempted and abandoned. One ligature was applied to the artery, two to the vein; and as much as possible of the diseased tissue, which extended deeply beneath the angle of the jaw, was scooped out previous to the application of zinc chloride paste with morphia. Zinc paste was applied at intervals, five times in all, the application being followed by pain on swallowing, so severe that gastrostomy was contemplated. Poultices and iodoform ointment were applied in the intervals between the applications. Subsequently dry tannic acid was dusted on the small remaining mass, a saturated solution of the acid in glycerine with carbolic acid being also applied. The original opening had greatly contracted; the incision made for the ligation had completely healed, and the patient was free from pain. Though his appetite was poor, he could eat food and swallow it; he was able to be up and to walk about the garden. A complete cure could hardly be hoped for, yet the relief and comparative comfort experienced by the patient showed how much might be done in apparently hopeless cases to mitigate pain and distress.

THE CHOLERA AND THE THAMES.

A LETTER signed "Anti-Panic" appears in the columns of the *Standard*, which very reasonably points out that great sanitary improvements have taken place since the last cholera epidemic visited these shores. But, if London is now well drained, the Thames is still polluted; and to this we might add that, if public authorities have built good sewers, private individuals have not always been equally successful in draining satisfactorily the interior of their dwellings. The correspondent to whom we allude considers that it is highly probable the cholera will reach London by next spring; but urges that between this and then works might be established at Crossness and Barking to deodorise the main sewer outfalls. This would at least mitigate the present dangerous and deplorable contamination of the Thames below London. The proposal to carry the metropolitan sewage to Sea Reach would not only cost some £4,000,000, but could not possibly be realised in time to protect us against the present danger. Deodorising is, therefore, for the present the easiest if not the best measure that can be adopted. This, however, would only improve the Thames at and below London. The intake for the water-supply at Teddington would not be rendered any the less exposed to the possibility of contamination from places situated higher up the river. A new water-supply, however, though urgent, cannot be extemporised in a few months; but the present danger should serve as a strong argument for those who, in the name of public health, have ventured to attack the vested interests of the water companies. In a word, our position has sufficiently improved to warrant a sense of confidence that should disarm panic-mongers; but this feeling of security must not be allowed to check the agitation in favour of further sanitary reforms. Apart from the menace of cholera, the daily increase of population renders these reforms more and more indispensable.

During the last summer the Metropolitan Board of Works spent a very large sum in the purchase of chemicals in attempting to deodorize the River Thames. This was naturally all wasted. It must not be forgotten that the nuisance during hot weather does not arise so much from the recent discharge of sewage as from that which has been deposited upon the banks and shoals for weeks and months, and is in a state of active putrefactive change. From this it will be seen that the use of chemicals must be carried on for a long period before the desired effect can be produced. It is the sewage of to-day which will cause the nuisance complained of months hence, and therefore it is the sewage of to-day which must be treated. If the Metropolitan Board of Works is anxious to prevent a recurrence of the awful condition of the river during last summer, let them begin steadily and quietly to treat the sewage during the months of spring and early summer, and in this way some temporary relief may be experienced in the hotter months.

INCREASE OF SMALL-POX.

SMALL-POX, as we anticipated, is, with the advent of colder weather, again steadily on the increase, and it is by no means improbable that during the coming winter a serious epidemic may prevail. The last returns of the Metropolitan Asylums Board tell of an increase of sixty-eight under treatment on the previous fortnight, and the mortality is shown by the Registrar-General's returns to be in the same direction. London has never had so complete an organisation for the isolation of small-pox as she now possesses, but it will have to be supplemented by efficient vaccination and revaccination, otherwise it may not be able to cope with such extension of disease as may be in prospect.

THE RABBETH MEMORIAL.

THE committee appointed to consider the best means of commemorating the name and self-sacrifice of the late Dr. Rabbeth have decided that this end will be best secured by the establishment of medals bearing his name at the London University and King's College, the endowment of children's cots at King's College Hospital and the Royal Free, and the erection of memorial tablets at these two institutions. We are informed that Sir Wm. Jenner has joined the committee and has sent a donation to the fund. We shall be happy to receive subscriptions towards the above object.

IN the course of an impressive sermon on Sunday last at Swanley the Rev. John Nowers, the present vicar in charge, dwelt at some length upon true heroism, illustrating his remarks chiefly by the contemplation of the characters of the heroes of sacred history. He referred also to the bright examples of the true heroism afforded us in the present age, alluding especially to the noble conduct of the King of Italy in personally visiting the cholera-stricken patients at Naples,

Digitized by Google

and to the noble and unselfish act of the late Dr. Rabbeth, who not only risked but lost his own life in endeavouring to save that of a poor little child.

ACCORDING to the *Gaulois*, a doctor engaged in the laboratory of Professor Vulpian has swallowed some pills made from the vomit of a person who died from cholera. The medical man is still in perfect health, but two guinea-pigs which were inoculated with the same vomit succumbed at once. The experiment was made with a view to proving that the microbes discovered by Dr. Koch are innocuous, and that the vomit of choleraic patients is not infectious.

IN an action brought on the 6th inst. at the Bristol County Court by the Incorporation of the Poor to recover £2 1*s.* 2*d.*, the cost of the maintenance and care of a child of the defendant in the hospital for infectious diseases for a period of five weeks, the judge ruled that, although the guardians had merely done their duty, as the child was removed without the consent of the father, judgment must be entered for the defendant.

THERE is a serious outbreak of diphtheria in South Mimms, near Barnet. The medical officer of health reports the condition of the village to be in a very unsatisfactory state from a sanitary point of view. Overcrowding exists to a large extent, and the drainage arrangements are seriously defective.

THE Technical Exhibition at Humphreys Hall, Knightsbridge, which was conducted under the able management of Mr. W. Southwick Rogers, was closed on the 12th inst. A substantial balance will be handed over to the funds of University College Hospital, in aid of which institution the Exhibition was inaugurated.

IT is stated that the Government contemplate the closure of several of the Dublin hospitals and the erection of a Government hospital on the plan of Guy's, with a school of medicine attached. The Government intend giving £150,000 towards the scheme, and it is rumoured that Lord Spencer will present £50,000 to the hospital.

MR. SAMPSON GAMGEE, F.R.S.E., has been elected a Corresponding Member of the Medical Society of St. Petersburg.

ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS.

A GENERAL meeting of this Association was held on Nov. 8th at the rooms of the Medical Society of London, 11, Chandos-street, W., Mr. Pollock in the chair. On the motion of Mr. JOHN TWEEDY, seconded by Mr. J. WICKHAM BARNES, Mr. Wheelhouse of Leeds and Mr. Bartleet of Birmingham were elected members of the committee of the Association.

Mr. BRUCE CLARK, one of the hon. secretaries, read a preliminary report, which showed that out of 254 Fellows who sympathised with the objects of the Association, he had received answers fully approving of the new recommendations and alterations proposed to be included in a new charter of the College from more than one-half of that number. A full statement of these recommendations may be found in THE LANCET for Nov. 1st, p. 795. The meeting then passed on to consider the recommendations.

Mr. J. WICKHAM BARNES then moved, as an amendment to the first recommendation, that "any Fellow of the College who has been a Fellow for ten years or a Member for twenty years shall be eligible to be a member of the Council." This was carried unanimously.

The next recommendation discussed was as follows: "That not more than one-half of the members of the Court of Examiners, and not more than two members of the Board of Examiners in Anatomy and Physiology, shall have seats in the Council." Mr. Brodhurst had written to Mr. J. H. Morgan, one of the hon. secretaries, to the effect that none of the members of the Court of Examiners should have seats in the Council.

Mr. BUTLIN thought that a half was too large a proportion, and suggested one-third.

Mr. ALLINGHAM was in favour of the original clause, as were also Mr. POLLOCK, Mr. OLIVER PEMBERTON, and others. The original proposition was carried.

Some discussion took place on the recommendation relating to the conditions and term of tenure of office of a member of Council. The report recommended "that the six members of the Council who shall have served longest on the Council without re-election shall vacate their office every year, instead of three members, as provided by Sec. 12, Chap. 7, Vict."

Mr. HICKMAN proposed an amendment to the effect that whenever one vacancy or more should arise otherwise than through retirement by rotation, only so many senior members of Council as would make up the number six should vacate. There should, he thought, always be the same number of vacancies; and it would be hard on some members of Council to make them seek frequent re-election.

Mr. ALBAN DORAN said that anyone acquainted with the mysterious formalities of the Council knew how impossible it was for junior members of Council to make themselves heard. It took a long time to learn the etiquette of the Council.

Mr. LOCKWOOD spoke against Mr. Hickman's amendment; and Mr. ALLINGHAM, as a member of Council, gave an amusing account of the mysteries of the ways and doings of that body.

Mr. J. TWEEDY said that, so far from hesitating about shortening the term of office of members of Council, he would not be sorry if all the members had to seek re-election every year. The scheme of combination between the Colleges of Surgeons and Physicians would never have been carried if the body corporate had been consulted. There was no advantage to be gained by Mr. Hickman's amendment. He felt sure that they would get no reform until the autonomy of the Council had been broken up.

Mr. POLLOCK and Mr. REGINALD HARRISON supported the proposal to let the original recommendation stand.

Mr. HICKMAN'S amendment was not supported and so fell through. The proposition relating to the abolition of "substitute members" was approved.

Referring to the approved recommendation respecting the mode of voting, Mr. TWEEDY proposed that at the annual general meeting the chairman should appoint three Fellows of the College as scrutineers to superintend the ballot or other mode of voting at the next election of members of the Council and of the president.

Mr. PEARCE GOULD, in seconding the amendment, suggested that the scrutineers be appointed at the Council meeting immediately preceding the annual election. This suggestion was adopted by the mover, and then the original amendment with this alteration was carried. When the section referring to the mode of election and tenure of office came forward for consideration, Mr. POLLOCK said that one member of the Council had informed him that the recommendation to elect the president by votes from the whole body of Fellows would be strenuously resisted by the Council.

The proposition "That the president be elected at the time and in the manner that members of the Council are elected, on the nomination of the Council" was commented on by Mr. WALTERS, who wished the addition of a clause empowering any body of thirty Fellows to nominate a candidate for the presidency.

Mr. COLLINS seconded this addition, but the proposal was negatived.

The recommendation "that no one shall hold the office of president for a longer period than five consecutive years" was objected to by Mr. J. W. BARNES, who moved that "three" be substituted for five years. After this had been seconded,

Mr. PEARCE GOULD spoke in favour of retaining the original recommendation, feeling that if the president were a good officer he could not receive too much distinction, and he also referred to the custom at the Royal College of Physicians.

Digitized by Google

Mr. JOHN H. MORGAN, hon. secretary, said that though such was the custom, yet there was no written law to support it.

Ultimately Mr. J. W. BARNES's amendment was lost.

As a suggestion for a bye-law, Mr. TWEEDY referred to the possibility of the occurrence at an election for the presidency of an equality in the number of votes polled for each of the three candidates. In such an event, he thought that the retiring president or, if he were not a candidate, the candidate who was the senior Fellow should be elected.

In dealing with the recommendation "that a treasurer be appointed from amongst the members of the Council, and that his accounts be audited by a professional auditor, whose report shall be submitted to the annual meeting of the Fellows and Members," Mr. POLLOCK expressed the opinion that the treasurer should be appointed for a term of years.

The practice at the Medical Societies was referred to by Mr. BUTLIN, who thought this matter might be left to the discretion of the Council of the College, a view which was accepted by the meeting.

Respecting the election of Fellows without examination some discussion was elicited. The recommendation of the Committee of the Association proposed that Section 5, Chap. 15, Vict., of the charter of the College be altered, so that instead of a possible annual election of two persons as Fellows without examination the number might be increased to five.

Mr. BUTLIN thought that the Fellowship should not be given too freely. He proposed that the original clause in the existing charter be not altered.

Mr. TWEEDY said he felt very strongly on this matter. It should be borne in mind that the Council had removed every restriction in the way of any Member of the College wishing to take the Fellowship. It was sufficient now for a Member to have been engaged for six years in the practice of his profession to qualify him for presenting himself for the final Fellowship examination. As only about fifteen to twenty Fellows by examination were made every year, he thought the possible creation of five Fellows without examination was too great a proportion. He therefore seconded Mr. Butlin's proposal, which was unanimously carried.

With regard to the election of Honorary Fellows, Mr. PEARCE GOULD thought that if the recommendation permitted only two distinguished members to be elected annually, the proposition would be more acceptable. He moved "That the Council every year may nominate two distinguished members of the medical profession, whether Members of the College or not, as Honorary Fellows to be elected by the Fellows and Members at the annual general meeting," which, after having been discussed by Mr. HICKMAN, Mr. ROYES BELL, and the CHAIRMAN, was seconded by Mr. BUTLIN, and carried unanimously.

The recommendation respecting meetings of Fellows and Members separately and collectively was also altered at the instance of Mr. TWEEDY, seconded by Mr. LOCKWOOD, so that the new proposition would read thus: "That there shall be an annual general meeting of the Fellows and Members on the first Thursday in July, on the day when the election of the Council takes place, at which the annual report of the Council, including the treasurer's statement of accounts, duly audited, shall be presented, discussed, and, if approved, adopted."

Mr. TWEEDY proposed, as a new clause, "That no bye-law, rule, regulation, or ordinance of the College shall be made, altered, or revoked without the consent of the Fellows and Members at the annual general meeting, or at a meeting specially convened for the purpose."

Mr. J. WICKHAM BARNES seconded the proposition, which was carried.

The other recommendations were adopted in the original form in which they had been drawn up by the committee of the Association.

It was then decided to leave to the committee what steps should be taken in order to acquaint the Fellows of the College, the Association of the Members, and the Council of the College with the proceedings which had occupied the Association of Fellows at their present meeting.

A meeting was held on Friday, the 7th inst., at 3, New Inn, Strand, to consider the alterations proposed by the Association of Fellows to be made in the regulations of the College. Approval was expressed of the first six clauses, but Clause 7 was unanimously objected to, and it was agreed to suggest to the Association of Fellows that this clause should read as follows: "That the Council of the College shall be elected by the Fellows and *Members* of the College, and that the president of the College shall be elected annually from amongst the members of the Council, and that no one shall hold the office of president for longer than three years." It was also suggested that in Clause 8, referring to the election of treasurer, the words "That a treasurer be appointed from amongst the Members" should read as follows: "That a treasurer be appointed BY the Members." The remaining clauses were thoroughly approved of, although it was considered that Clause 10, referring to the Board of Examiners in Anatomy, would be improved by the addition to it of the following words: "That should any Member of the College be elected a member of the Board of Examiners, he shall by virtue of such election become a Fellow of the College."

Great disappointment was expressed at the manner in which the Fellows had ignored the right of the Members to vote in the election of the Council, without which the Members would have no voice in the government of the College.

After the propositions of the Fellows had been considered, an animated discussion followed in reference to the difficulty students experienced in obtaining a medical degree in London. A strong opinion was expressed that the General Medical Council had greatly neglected the welfare of the profession, and that the interests of the great mass of the profession were not represented on it, and were not protected by it.

THE CASE OF LIEUT. HUBBARD.

WE are indebted for the following notes to Dr. T. B. Adam, surgeon to the Native Hospital and Dispensary, Foochow:—

With the permission of Surgeon Lory I send you the following notes of the case of Lieut. Hubbard, H.M.S. *Zephyr*, who recently succumbed to injuries inflicted by a shell, fired by mistake from a Chinese fort in the river Min. Apart from the public interest necessarily attaching to such an unfortunate occurrence, the history of the illness has a medical value, and raises important questions. I saw Lieut. Hubbard for the first time, in consultation with Dr. Lory, about 2 P.M. on Sept. 6th, the injury having been received about 9 A.M. on the same day. I found him suffering pretty severely from shock; the lips were pale, with cold perspiration. The left leg and foot were very much swollen, the skin was very tense, and on the foot bluish discolourations were present. A wound of about one inch in extent existed over the fibula, about two inches above the malleolus. The fibula was fractured. Chloroform was given, and the wound enlarged to about five inches. The fibula was found obliquely fractured, a partially loose splinter intervening. One of the ends of the fractured bone had been driven inward, and divided the anterior tibial artery; hence internal hæmorrhage. The muscles of the calf tended to protrude through the incision, being much infiltrated with blood coagula. Having tied the anterior tibial artery at both ends, the tourniquet was removed, a few bleeding points secured with ligatures, and the wounds dressed with carbolic oil. Shortly afterwards Lieut. Hubbard was removed ashore, where comfortable accommodation had been provided. Throughout the afternoon hot fomentations were applied to the injured limb; and in the evening, the tension of the skin having quite disappeared, and circulation being perfect in the foot, the wounds were washed out with carbolic lotion and antiseptic dressings applied. Pott's splints were fixed on either side of the leg, outside the dressings.

Sept. 7th.—Patient passed a good night; shock perfectly recovered from; temperature normal; leg dressed under spray; swelling found decreasing; wounds antiseptic; sensation perfect everywhere, save in bruised skin over the front of the ankle. Inside splint dispensed with.—8th: General condition good; in the morning the leg was again dressed; swelling still further decreased; wounds perfectly moist; skin of calf and foot present the varied hues of colour characteristic of normal absorption of effused blood. Throughout the day temperature was strictly normal, but in the evening the patient became a little restless, and the temperature rose to 101·8° in axilla; no preceding chill; no pain

Digitized by Google

in limb; five grains of quinine given.—9th: Spent a restless night; no special complaint, however, of pain or trouble anywhere; temperature in the morning still high, 101°; leg dressed; wounds free from discharge; no tension in limb; swelling still satisfactorily decreasing. During the day restlessness increased, and in spite of frequent doses of quinine the temperature rose in the evening to 103°.—10th: Had passed an unsatisfactory night; while tossing about patient had jerked the leg somehow, acute pain followed from which relief was only obtained by a sleeping draught. In the morning the dressings were changed; swelling had occurred in the lower parts of the leg and around the ankle. Circulation and sensation in foot, however, were perfect. To relieve the slight tension of skin the wound over fibula was extended about one inch, above and below. The cuts made bled freely; the wounds were dressed with carbolic oil, a layer of salicylic wool was wrapped round the limb, and an antiseptic bandage applied over all. Splint dispensed with. Limb felt more comfortable after dressing, but the patient's general condition was most discouraging. Temperature throughout the day continued about 103°, skin dry and hot, no other symptom being present, however, save marked restlessness. Quinine and stimulants given freely, with opiates.—11th: During the first part of the night the patient had been restless, but towards midnight pain left the limb, and he slept well till morning. At 8 A.M. the left knee joint and lower part of thigh were much swollen, and skin thereof had a peculiar livid colour. On opening the dressings the whole leg was found cold, and in a state of complete gangrene. Patient's breath had a marked gangrenous odour. No attempt at a line of demarcation was perceptible in the thigh. Temperature 103°. Amputation was at once performed in the upper third of the thigh. Dr. Rennie, who was called in consultation, operated. Patient rallied successfully from shock. The evening temperature rose again to 102°.—12th: More or less delirious all night. In the morning the intellect perfectly clear. Temperature 103°, pulse 140. Cold perspirations. On removal of the dressings the flaps were found gangrenous. Patient passed the day perfectly free from pain, intellect unclouded, and spirits marvellously cheerful, though fully informed of his condition. Lost consciousness only about an hour before death, which occurred early in the morning of the 13th.

Remarks.—With such a history as the above before one, the question is naturally asked, Was this a case in which a life was sacrificed in a mistaken zeal to save a limb? For two days and a half progress towards recovery was all that could be desired; the wounds were perfectly antiseptic, and the effused blood was being rapidly absorbed; fever then occurred. The patient's constitution was unfortunately not a good one. Previously stationed on the West Coast of Africa, Lieutenant Hubbard had suffered severely from malarial fever, been invalided home on that account, and had left the Naval Hospital but a few weeks when he started for the China station, eleven months ago. For the first thirty-six hours of the fever the injured limb continued apparently to make satisfactory progress; acute pain then occurred from some sudden movement on the patient's part. On the following morning a suspicious increase of swelling around the ankle was noted. The most serious view of the case was taken, and the question of the patient's chances for life was discussed. With the grave constitutional disturbance present, and no signs of failure of circulation in the injured limb, both Dr. Lory and myself were agreed that amputation at that moment would be unwise and unjustifiable. Relief of all tension in the limb, and efforts to reduce fever, were the measures adopted. Perhaps we were wrong, but of that I am yet in doubt. The waste products poured into the blood by lymphatics from the injured limb would, of course, supply fuel for the fever flame, but the repair of a thigh stump also calls for active tissue changes, and these, *plus* the depression to the system from the shock of the operation, could scarcely result in abatement of fever. In spite of all endeavours, however, the high fever continued, and this, with the accompanying rapid circulation, soon proved too much for the injured limb. During the night of the 10th venous return was blocked, and a very few hours with such high temperature sufficed to bring about the state of affairs found on the morning of the 11th. The amputation then performed I admit was hopeless and a questionable proceeding, but by securing to the patient comfort during the remaining forty hours of his life, the end, I think, justified the deed.

Roseberry, Sept. 18th, 1884.

THE DESTRUCTION OF CHRISTIANSBORG PALACE.

REPLY OF THE KING OF DENMARK TO THE ADDRESS BY THE ENGLISH, SCOTTISH, AND IRISH MEMBERS OF THE INTERNATIONAL MEDICAL CONGRESS.

THE following letter has been sent to us for publication:—

British Legation, Copenhagen, November 3rd, 1884.

SIR,—I beg to inform you that the King was graciously pleased to receive me to-day in private audience for the purpose of delivering to His Majesty the address, signed by the English, Scottish, and Irish members of the International Medical Congress recently assembled here, expressing their profound regret at the loss sustained by His Majesty and Denmark in the destruction of Christiansborg Palace on the 3rd ult. The King seemed fully to appreciate this graceful tribute of sympathy, and commanded me to convey to its authors his "heartfelt thanks."

I am, Sir, your most obedient humble servant,

AUDLEY GOSLING,
Her Majesty's Chargé d'Affaires.

Henry Morris, Esq.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5784 births and 3569 deaths were registered during the week ending the 8th inst. The annual death-rate in these towns, which had been equal to 20·9 and 20·6 per 1000 in the two preceding weeks, rose last week to 21·3. The lowest rates last week were 16·6 in Birkenhead, 17·1 in Brighton, 18·0 in Portsmouth, and 18·3 in Birmingham. The rates in the other towns ranged upwards to 25·9 in Newcastle-upon-Tyne, 26·0 in Liverpool, 27·4 in Cardiff, and 31·5 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 390 and 379 in the two previous weeks, rose again to 392 last week; they included 82 from scarlet fever, 79 from measles, 73 from diarrhœa, 60 from "fever" (principally enteric), 26 from diphtheria, and 23 from small-pox. No death from any of these diseases was returned last week in Brighton, whereas they caused the highest death-rates in Bolton, Preston, and Cardiff. The greatest mortality from measles was recorded in Bolton, Preston, and Cardiff; from scarlet fever in Sunderland, Sheffield, and Newcastle-upon-Tyne; from whooping-cough in Bradford and Leeds; and from "fever" in Leeds, Derby, and Blackburn. The 26 deaths from diphtheria in the twenty-eight towns included 17 in London, 3 in Liverpool, 2 in Portsmouth, and 2 in Newcastle-upon-Tyne. Small-pox caused 22 deaths in London (exclusive of 7 London cases registered outside Registration London), and 1 in Sunderland. The number of small-pox patients in the metropolitan asylum hospitals, hospital ships, and camps, which had been 596 and 580 on the two preceding Saturdays, rose to 675 at the end of last week; the admitted cases, which had been 173 and 101 in the two previous weeks, rose to 233 last week. The Highgate Small-pox Hospital contained 30 patients on Saturday last, 18 new cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had steadily increased in the seven preceding weeks from 159 to 348, further rose last week to 357, but were 78 below the corrected weekly average. The causes of 91, or 2·6 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Brighton, Bradford, Sunderland, and in three smaller towns. The largest proportions of uncertified deaths were recorded in Norwich, Halifax, and Wolverhampton.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 21·4 and 22·5 per 1000 in the two preceding weeks, further rose to 22·6 in the week ending the 8th inst.; this rate was 1.3 above the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 13·4 and 14·1 in Perth and Leith, to 25·5 in Glasgow and 28·5 in Aberdeen.

Digitized by Google

The deaths in the eight towns included 93 which were referred to the principal zymotic diseases, against 110 and 116 in the two previous weeks; 21 resulted from diarrhœal diseases, 19 from measles, 18 from scarlet fever, 18 from diphtheria, 11 from whooping-cough, 6 from "fever" (typhus, enteric, or simple), and not one from small-pox. The rates from these diseases averaged 3·8 per 1000 in the Scotch towns (against 2·3 in the twenty-eight English towns), and ranged from 0·0 in Perth to 4·7 in Aberdeen and 5·5 in Glasgow. The 19 fatal cases of measles showed an increase of 5 upon the number in the previous week, including 12 in Glasgow, 5 in Aberdeen, and 2 in Dundee. The 18 deaths from scarlet fever, including 15 in Glasgow, were fewer by 7 than those in the previous week, and the deaths referred to diphtheria, which had been 17 and 20 in the two preceding weeks, declined again to 18 last week, of which 6 were returned in Glasgow, 4 in Dundee, 3 in Aberdeen, and 2 in Edinburgh. Seven of the 11 fatal cases of whooping-cough (but half the number in the previous week), and 5 of the 6 of "fever" (also but half of the number in the previous week), occurred in Glasgow. The 21 deaths attributed to diarrhœal diseases showed a decline of 2 from those in the previous week, but exceeded the number in the corresponding week of last year by 4. The 119 deaths referred to acute diseases of the respiratory organs in the eight towns showed a further increase of 7 upon recent weekly numbers, and were 28 above the number in the corresponding week of last year. The causes of 60, or 11 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 30·2, 26·8, and 24·7 per 1000 in the three preceding weeks, rose again to 25·3 in the week ending the 8th inst. During the first six weeks of the current quarter the death-rate in the city averaged 27·0 per 1000, whereas it did not exceed 18·8 in London and 17·8 in Edinburgh during the same period. The 170 deaths in Dublin last week showed an increase of 4 upon the number in the previous week, and included 18 which were referred to the principal zymotic diseases, against 29 and 25 in the two previous weeks; 8 resulted from scarlet fever, 6 from diarrhœa, 1 from measles, 1 from diphtheria, 1 from "fever" (typhus, enteric, or simple), 1 from whooping-cough, and not one from small-pox. These 18 deaths were equal to a zymotic rate of 2·7 per 1000, the rate from the same diseases being equal to 2·2 in London and 1·5 in Edinburgh. The deaths from scarlet fever, which had been 12 and 10 in the two previous weeks, further declined last week to 8; the fatal cases of "fever" and whooping-cough were also fewer than those in the previous week. The 6 deaths from diphtheria, however, exceeded the number in the previous week by 2. Four deaths resulted from violence and 44 were recorded in public institutions. The deaths of infants showed an increase, while those of elderly persons were fewer than in any recent week. The causes of 20, or nearly 12 per cent., of the deaths registered during the week were not certified.

VITAL STATISTICS OF JAMAICA.

The fifth annual report of the Registrar-General of Jamaica deals with the vital statistics of that island during the year ending September, 1883. We must once more protest against these reports relating to years ending with the third quarter of each year, thus in great measure destroying the value of their statistics for comparative purposes. The population of this island, which was 580,804 at the last census in 1881, is estimated to have now increased, by excess of births over deaths, to 600,000; this increase during the twelve months under report amounted to 10,735. The rate of marriages did not exceed 4·9 per 1000, but showed an increase upon still lower rates in previous years. The condition of elementary education in Jamaica may be inferred from the fact that 49 per cent. of the males and 69 per cent. of the females who married during the year signed the marriage register with a mark. The birth-rate in the year was 41·5 per 1000. The low marriage-rate in part explains the fact that no fewer than 61 per cent. of the births registered during the year were illegitimate. The death-rate of the island during last year did not exceed 23·0 per 1000, but the 13,397 deaths showed an increase of 1523 upon the number in the previous year. The deaths included 3695, or 27·6 per cent., of infants under one year of age, and 5555, or 41·5 per cent., of children under five years of age. Measured by the proportion of deaths under one year to births, infant mortality was equal to 153 per 1000, which, considering the tropical climate and the large proportion of illegitimacy, may be considered low. In the town of Kingston, however, infant mortality was equal to 226 per 1000, and slightly exceeded, as is pointed out in the report, the mean rate in Liverpool during the eight years 1870–77. It is noteworthy as evidence of the insanitary condition of Kingston, the capital of Jamaica, that the deaths exceeded the births by 718 during the five years ending September, 1883. As regards the causes of death in Jamaica, the information, although given in considerable detail, is bereft of most of its value from the fact that medical certificates are obtained in so small a proportion of the deaths. During the year under report professional certificates of the causes of death were only obtained in 2459 cases out of 13,397 deaths. It follows, therefore, that in 81 per cent. of the deaths recorded in Jamaica during the year under report no trustworthy information as to the cause of death was obtained. In face of the unsatisfactory nature of the return of causes of death, it appears to be under consideration whether the present detailed statistics of causes of death should be maintained. It may be hoped that means may be found to increase the proportion of certified cases rather than to discontinue these statistics. It is important from a public health as well as from a statistical point of view to secure an increased proportion of medical attendance in Jamaica, and this will be more probably attained by means of the attention drawn to such statistics as are now given, than by discontinuing them. In the early days of registration in this country the proportion of uncertified deaths was nearly as large as it now is in Jamaica, whereas it is now reduced to 4 per cent.

Correspondence.

"Audi alteram partem."

"LAWN TENNIS LEG."

To the Editor of THE LANCET.

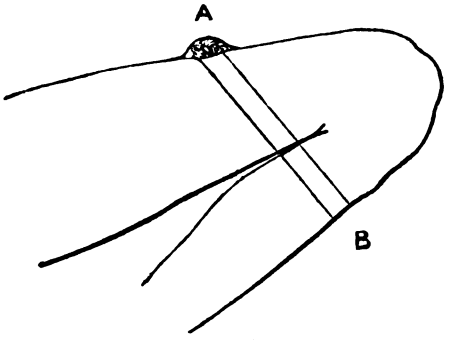
SIR,—I read with much interest Dr. Wharton P. Hood's paper in your issue of Oct. 25th on the above subject. I met with the accident he describes more than twenty years ago. I was running to overtake a messenger when I felt the sharp pain in the calf of my leg, and should have fallen on the ground had there not been some iron railings to which I clung. I limped home, and reached my house about an hour after the receipt of the injury. The calf of my leg was swollen and tense, and on running my finger down the leg it entered a sulcus, giving exquisite pain. I put my leg into a bucket of hot water, which gave relief, but when I tried to walk a few steps the pain was so great that I found progression difficult. As the pressure of my hands relieved the pain, I applied a calico bandage from the instep to the knee. To my delight I found I could walk well and without pain. I wore the bandage for a fortnight, and was not kept at home a day. As I was ignorant of the nature of the injury I had met with, I searched for information in books. I found a paper in the seventh volume of the Transactions of the Medico-Chirurgical Society by the late Mr. James Wardrop read May 23rd, 1815, in which the injury is well described and the treatment advised by Dr. Hood inculcated. Two cases are given in illustration.

I am, Sir, yours truly,

CLEMENT HAWKINS, F.R.C.S.

Cheltenham, Nov. 5th, 1884.

DOUBLE WOUNDING OF TWO PARTS OF A LIMB.



To the Editor of THE LANCET.

SIR,—The following case may be of some interest in relation to Brigade Surgeon Hinde's report of a gunshot wound of the hand and upper arm in THE LANCET of October 25th.

Some years ago I saw a young gentleman who had received the charge of a fowling-piece in his lower extremity. There was a wound of entry on the anterior part of the inner face

Digitized by Google

of his leg, one of exit on the posterior part of the same surface. This having been looked to, he complained of stiffness in front of the thigh, where I found a lump of small shot under the skin. On searching to find how they got there, I discovered a wound of entry on the back part of the inner face of the thigh and a hollow between it and the shot; so we had two wounds in the leg and a transverse subcutaneous passage; one wound in the thigh with an obliquely

A, Charge of shot. B, Wound of entry.

ascending hollow to the place of lodgement of the shot. Let anyone bend his leg to the full extent on the thigh, and he will at once see that the line of the course of the charge becomes a straight one, as in the above diagram, though the two lines of traverse were so distinct and differing in direction in the straight position of the limb.

I am, Sir, yours truly,
W. W. MOXHAY,
November, 1884. Surgeon, Royal Berks Hospital.

DEATH DURING THE ADMINISTRATION OF METHYLENE.

To the Editor of THE LANCET.

SIR,—I beg to report the following case of death under methylene.

John B——, aged nineteen, a miner, was injured six months ago by an explosion of gunpowder while he was "tamping" a hole. A number of pieces of stone were blown into his arm, and his right ulnar nerve was divided. On Sept. 19th, he was put under methylene in this hospital, and several pieces of stone were removed. On that occasion he took the anæsthetic perfectly well. On Oct. 17th he was brought into the theatre for suture of the ulnar nerve, when methylene was given on a leather mask. The patient took the anæsthetic badly from the commencement, struggling violently, and it was with difficulty that anæsthesia was induced. The pulse during the induction was good, but on the commencement of the operation the patient became rapidly cyanosed, and the heart's action suddenly ceased, the pulse having given no indication of danger.

A post-mortem examination was made by order of the coroner, when the right ventricle was found full of blood, and the left ventricle slightly hypertrophied and contracted. The valves of the heart were quite healthy.

I may mention that a sample of the methylene used was tested, and found to be pure.

I am, Sir, yours faithfully,
W. A. BUCHAN, M.D., House Surgeon.

South Devon and East Cornwall Hospital, Plymouth, Nov. 4th, 1884.

EXAMINATION OF ARMY MEDICAL OFFICERS.

To the Editor of THE LANCET.

SIR,—I do not see that the valuable suggestion made in your issue of the 25th ult., on the examinations for army medical officers, has attracted the attention it deserves.

With regard to the new examination for Surgeons-Major you offered two suggestions, one of which the revised circular issued last month has anticipated, and concerning which therefore no more need be said. The other, and to my mind far the more important of the two, is still a suggestion, and nothing more. It is this: that it should be possible for surgeons-major to take the examination earlier than after twenty years' service. This seems to be a most judicious proposal and if carried out would remove the only reasonable objection that can be alleged against the examination. That it is a reasonable objection there can be no doubt. As it stands now, an officer has hanging over him this ordeal for years, and he cannot get through it until he is over forty. Why should this be? The average individual in the forties is taken up with the practical side of things, and to have to undergo yet another examination at such an age is an anachronism which must be particularly irritating. He is called upon to renew the days of his youth without being able to feel young. There is a time for everything, and in the fitness of things that for examinations should end with a man's eighth lustrum at furthest. Why should it not be taken after fifteen years' service instead of twenty, and so at once get rid of the only other remaining objection to the examination? I commend this to the consideration of your readers; and in connexion with your remarks of the 26th ult., on the elderly surgeons-major, who are close on fifty and yet must undergo examination, no doubt the new rules press hardly. I would say to them take a broad view of the subject. As the principle underlying these examinations is recognised as a sound one, it follows that in the interests of the State they should be carried out in practice without delay. Individual interests must yield, but the officers may depend upon it that evidence of good practical knowledge, the natural outcome of their experience in various climates, will be the thing looked for in the examination, and least of all will it be one of books and cramming.

I am, Sir, yours truly,
Nov. 2nd, 1884. G.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

HOSPITAL ACCOMMODATION IN NEWCASTLE AND GATESHEAD.

AN important meeting was held at the Newcastle Infirmary on the 6th inst. to receive the report of a special committee appointed to consider the subject of increased room for patients. The committee recommended very strongly the erection of a new wing on the present site, and in connexion with the existing building; this, if carried into effect, would admit of 100 new beds being put up at an expense of probably £25,000. Lord Ravensworth (who presided) supported the recommendation, and thought that extension of the present building was far more feasible and economical than any project for removal of the infirmary, or, in other words, the erection of a new building. Dr. Gibb also advocated very strongly the retention and extension of the present building. Dr. Heath, on the other hand, along with others, was strongly opposed to the present building, which he thought was objectionable from many points of view, and showed with much force that the present objections would increase rather than diminish, and the removal of the building would have to be ultimately faced whatever were done at present. It cannot be disputed that the situation of the Newcastle Infirmary is about as bad as it could be, regarded from a sanitary or hospital point of view, surrounded as it is by a cattle-market goods station of the North-Eastern Railway, and receiving pollution of its atmosphere from the smoke of the Tyne, and from the evacuations of many of the factories of Newcastle and Gateshead. Dr. Newcombe of Gateshead writes to our papers to point out that the time is ripe for the extension of the Gateshead Dispensary into an hospital for that borough, and he contends that the wants of the public would be better fulfilled, instead of spending a large sum of money on enlarging the Newcastle Infirmary, by building a permanent one in Gateshead in the midst of a teeming population. Many will agree with Dr. Newcombe as to the absolute necessity for a hospital in Gateshead, but the whole question is opened now, and is certain to be fully gone into, and I shall endeavour to make you aware of the feeling on the subject as regards both sides of the Tyne.

SMALL-POX IN THE CITY OF DURHAM.

There is as yet no sign of any subsidence of the small-pox epidemic in Durham, which has become very serious and is having a disastrous effect on the trade of the place, a matter of much consequence at the present time. A public meeting has been held calling on the sanitary authority to provide adequate hospital accommodation, and the Dean and Chapter

Digitized by Google

of Durham have offered to assist in the way of providing a suitable site for an infectious hospital. Dr. Barron, the medical officer of health, has stated that the disease had abated neither in extent nor in strength; this might be inferred from the fact that, of twenty-one deaths which had been ascribed to small-pox, no less than fifteen had occurred in the month of October. Dr. Barron has all along urged upon the authority the duty of providing a hospital, and at one time his advice appeared to have been taken; but then, again, the authority, in the strangest possible manner, rescinded its own motion on the subject. Now, however, it is felt that the pressure of public opinion will prove too strong for this stolid and inert body.

NORTH RIDING INFIRMARY, MIDDLESBRO'.

A meeting of governors of the North Riding Infirmary was held last week to fill the appointment of house-surgeon. There were no less than thirty-nine applications for the post; out of these the house committee made a selection of four, and from these an election took place by ballot. The choice of the governors fell upon Dr. Fraser of Edinburgh, who was elected by a large majority.

THE LATE MR. JOHN TAYLERSON, M.R.C.S., WHITBY.

The recent death of Mr. John Taylerson of Whitby has deprived that town of its oldest practitioner, and one of its most prominent medical men. Mr. Taylerson was appointed medical officer for the workhouse as far back as 1838, so that he would be also one of the oldest Poor-law medical officers in the kingdom. I mentioned Mr. Taylerson's declining health a short time ago, when he received a useful testimonial from his fellow-townsmen, with many expressions of sympathy from them in his affliction. The late gentleman was distinguished by his kindness to his poorer patients, and some time ago, when a movement was made to curtail the supply of stimulants to the workhouse, he plainly told the guardians that to do so with his feeble patients would be to shorten their lives, and left the responsibility with the guardians; a course they were reluctant to take, and here, I believe, the subject ended.

Newcastle-on-Tyne, Nov. 10th

GLASGOW.

(From our own Correspondent.)

OPENING OF THE MEDICAL SCHOOLS.

THE various medical schools of this city are now in the full swing of their winter work. At the University the session was opened by a most thoughtful and interesting address by Professor Leishman on preliminary education, the medical curriculum, and the general spirit in which the work of student and practitioner should be done. Under the latter head his remarks were unusually plain and to the point. He deprecated the cry for legislative protection against quacks; so long as there was no limit to human credulity there was no possibility of suppressing quackery. There were quacks within as well as without the pale of the profession, and he took it that the moral turpitude of these was even greater than that of the bolder rascal who could not shelter himself behind the robe of a professional title. Speaking of the profession generally, he said that as practised by some, indeed he might confidently say by many, the profession merited all that could be said in its favour; but they must not fancy that the mere registering of their names, which legally constituted them medical practitioners, necessarily entitled them to share in the encomiums which the conduct of some had called down on the profession as a whole. There was this, he thought, to be said in favour of their calling, that it was one in regard to which it might confidently be asserted that any man might command moderate success—or, if they preferred to put it in that way, a moderate livelihood. He knew of no profession, of no department of commercial life, in regard to which the same might be said with equal confidence. But certain preliminary conditions were essential to success, however moderate, such as energy, punctuality, sobriety; while habits the opposite of these almost certainly led to failure.

At the Andersonian College the introductory address was delivered by Dr. Thomas Barr. After a few words of welcome and advice to the students, the lecturer entered on the discussion of certain matters which he hoped would soon engage the attention of Parliament. He said that education was an important thing no doubt, but the people required as yet to be educated as to the value of good health. To a working man a good constitution was really of more account than the three R's. He would therefore urge the electors to call for legislation in the following directions:—The compulsory inspection and supervision of drainage, water and milk supplies, the purification of the air of large cities by freeing them as far as possible from smoke and chemical vapours which generally covered them as a pall, increase of air-spaces in cities, and instead of having closely built double rows of black buildings, to have the houses built on open sites, with spaces adjoining planted with trees and flowers, in which the wives and children of the operative classes could take the air instead of having in many cases to go to the inaccessible outskirts; the controlling of the erection of dwelling-houses so that they might at least be as comfortable as reformatories or barracks; the compulsory registration of cases of sickness, and the protection of people against infectious disease; the purification of rivers; and the compulsory education of children in matters relative to health. In conclusion, he said that before another year the medical school might be removed westwards, and the old Andersonian building entirely devoted to the teaching of science.

At the Royal Infirmary School, Dr. J. Glaister, after cordially welcoming the students, delivered an address on a matter of very great importance—namely, the necessity for legislative reform in regard to uncertified deaths in Scotland. Uncertified deaths, he said, had a tendency to lead to the commission of secret crime or culpable neglect. The present state of things had not been overlooked, for municipal authorities, medical corporations, and medical societies had all made representations in order to have the number of uncertified deaths lessened; and as the question had now come again to the front it ought to be pushed to an issue. Having said that the State ought to be able to account for the death of every unit of the population, and that the larger the number of uncertified deaths under a given system of legal registration the greater the evidence there was that the machinery was not being worked effectively, and that there existed some defect in the law which required alteration, Dr. Glaister proceeded to state that in 1882, in Glasgow, nearly 9 out of every 100 deaths were uncertified; in Aberdeen nearly 4; in Greenock 10; in Leith nearly 11; and Perth 6½. If they took a series of years, from 1881 to 1883, he found that the total number of uncertified deaths was declining. In Glasgow, in 1882, the total number of uncertified deaths amounted to 1137; Aberdeen, 85; Greenock, 162; and South Leith, 91. In order to show how much Glasgow had improved in the last twelve years the lecturer mentioned that in 1872 the uncertified deaths numbered nearly 23 out of every 1000 deaths; or, in plain figures, 3281 people died the causes of whose deaths were not known. The change for the better had been mainly due to the operation of the Friendly Societies Act.

DR. RUSSELL ON DISINFECTION.

In a paper read recently by Dr. J. B. Russell, on "Disinfection," we find him returning to simple washing as the most easy and practical means of disinfection. Speaking of its efficacy as a disinfecting process he says, "I am able to establish my opinion from the experience of many years, during which this has been the sole method of disinfection applied by the sanitary department of Glasgow to all washable articles. We have during the last ten years washed in the same washing-house over a million of articles of every sort infected by every variety of contagion known in this country. Everything has been done exactly as any good housewife would do it, only in a place provided for the purpose, and with ample supply of water and steam, and recently with mechanical aid. Blankets and woollen articles have not been boiled; all others have. The most crucial fact is this, that there has never been a single case or suspicion of a case of interchanged disease—e. g., of small-pox—appearing in a house from which clothes had been removed on account of scarlet fever or typhus. In short, I am convinced that in every case the result was obtained for which the operation of washing was undertaken." An apparatus for disinfection by high-pressure steam had to be discarded, as this fixed in the fabrics all kinds of stains from animal matters, such as blood, fæces, pus, &c.

THE LORD RECTORSHIP.

The lamented death of Mr. Fawcett has rendered vacant the office of Lord Rector of Glasgow University. To avoid a contest for the office, the students' Conservative, Liberal, and Independent Clubs unanimously requested Mr. Robert Browning to accept the rectorship, but he declined. Mr. Matthew Arnold's name was then proposed, but the Clubs failed to agree on the matter. Finally, a unanimous requisition was sent to Mr. E. L. Lushington, LL.D., D.C.L., who was long the occupant of the Greek chair in the university. Should he accept nomination, his return is certain. The election must take place not later than Nov. 15th.

IRELAND.

(From our own Correspondent.)

ROYAL COLLEGE OF SURGEONS IN IRELAND.

At the recent examinations for the Second Professional Examination of this College a large number of the candidates were unsuccessful; and as it would be an extreme hardship for these candidates not to be re-examined until July next, applications for a Supplemental Examination were last week brought under the notice of the Council. It is expected that the latter body will grant a Supplemental Examination to take place next March, and also give credit for the lectures and hospital taken out this session. Under the new scheme of the College, the examinations take place at certain periods—viz., July and October; and supposing a student to be rejected in the latter month, he cannot take out any lectures or hospital for that session, but, losing an entire year, must await the examination of the following July. If the extra examination be refused, those unsuccessful at the recent examinations will almost to a man leave the College, and obtain diplomas from other licensing bodies. Complaints have been made by many that some of the examiners do not confine themselves as strictly as they might to the subjects prescribed in the curriculum for the diploma of the College, and if this be correct the Council should undoubtedly interfere and prevent a recurrence of the evil.

MEATH HOSPITAL, DUBLIN.

Last week the annual dinner of old past students and governors of the Meath Hospital was held at the Shelbourne Hotel, presided over by Dr. William Moore, ex-president of the College of Physicians. The meeting was a very successful one, the toast of the evening, "The lecturer of the day, Professor Rawdon Macnamara," being proposed by Dr Cameron, vice-president of the Royal College of Surgeons, and suitably acknowledged. I may add, as an interesting fact, that in 1776 one of the first entries in the earliest minute book of the hospital, which was then located in Earl-street, states that the annual dinner of the governors took place at three o'clock at the Phœnix, in Werburgh-street, the cost of the dinner being 2*s.* 8½*d.* each.

"THOMPSON MEMORIAL HOME."

Situated in the district of Magherafelt, near Lisburn, the Home, erected to the memory of the late Dr. William Thompson, is now almost completed. The deceased was a distinguished surgeon, and enjoyed a most lucrative practice, and as a fitting tribute to his memory his family have raised a Home for convalescent patients, as the late Dr. Thompson had often regretted the want of an institution of the kind. The Home stands on some nine acres of ground, handsomely planted, while the cost of building, furnishing, and fitting up the hospital will be about £20,000, a similar amount being allocated as an endowment fund.

MEDICAL ETIQUETTE.

A very disagreeable circumstance connected with one of our city hospitals, in which the resident surgeon and one of the visiting staff were engaged, was the subject of comment in medical circles this week. I do not deem it necessary to enter into the particulars of the dispute, but will merely remark that hostility between the colleagues of a hospital must be prejudicial to the general interests as well as to the students of any institution in which it occurs. Would that it were the only hospital in Dublin where such a condition of matters exists.

Dr. J. Magee Finny has been elected President of the University of Dublin Biological Association for the ensuing year.

The Rev. S. Haughton, M.D., has been granted by the Royal Irish Academy a sum of £15 in supplement of a grant of £35 to defray the expenses of calculation of sun-heat co-efficients and radiation.

Dublin, Nov. 11th.

PARIS.

(From our own Correspondent.)

THE LATE DR. FAUVEL.

I HAD just posted my letter of last week reporting the serious illness of Dr. Fauvel from double pneumonia when I heard of his death—that is, in the afternoon of Wednesday last, the 5th inst. Dr. Sulpice-Antoine Fauvel was born in 1813. He took his degree in 1840, and was for a long time physician to the Hôtel Dieu, from which post he retired only five or six years ago, when he attained the age limited for hospital physicians. He was, however, retained on the honorary list in recognition of his valuable services. He was a member of the Academy of Medicine since 1869, and was elected its vice-president this year. He was for many years Inspector-General of the Sanitary Department of France, which appointment he resigned only three months ago owing to failing health. But it was more as a hygienist than as a practising physician that he had distinguished himself. It will be remembered that, at the outbreak of the cholera epidemic at Toulon, Dr. Fauvel expressed himself to the effect that the disease was not the Asiatic cholera, but the sporadic form, that consequently it was not imported but engendered by local causes, and that it would not extend beyond a very limited zone. This opinion he held to the day of his death, notwithstanding that events have proved that he was wrong in his prognostications. At the various discussions on the subject in which he took part, either in person or in writing, he met with vehement opposition, some of his opponents being amongst his best friends and former pupils; yet nothing could convince him, and he lived just long enough to know that the cholera had not only extended to other parts, but that it had reached Paris itself. This, I am told, affected his health, and contributed in no small measure to the development of the disease which carried him off in three days. Dr. Fauvel had acquired a great reputation and authority on all questions touching public sanitation. He was the representative for France at two International Sanitary Congresses; the first was held at Constantinople in 1867, and the second at Vienna in 1874, when the conclusions adopted at Constantinople were overthrown, in spite of Dr. Fauvel's efforts to maintain them. In 1881 new regulations respecting the maritime sanitary arrangements of the French ports were published in the official journal, the measures recommended being those decided upon at the Vienna Congress, and are now in vogue. In practice Dr. Fauvel confined himself more especially to the treatment of phthisis and contagious affections. His researches on the nature and progress of epidemics of cholera, of the plague, of typhus, &c., raised him to the rank of an epidemiologist of the first order. He was a man of peculiar disposition and rather reserved in his manner. A *confrère* the other day, speaking of the deceased physician, observed to me: "Il était très estimé, mais pas aimé," which I thought very expressive of the feeling entertained towards him. He was Officer of the Legion of Honour, and had many other foreign decorations conferred on him. He leaves three daughters and two sons, one of whom has just taken his degree and promises to be a distinguished biologist, if one may judge from the papers he has already submitted to some of the learned bodies in Paris.

THE LATE DR. HENNINGER.

Dr. Henninger, one of the youngest agrégés of the Paris Faculty of Medicine, has just died. His death will be considered a great loss to science, as he was a promising young man. He took his degree only in 1878, and yet he held many distinguished positions. He presided over the Section of Chemistry at the Scientific Congress recently held at Blois. He was a favourite pupil of the late Professor Wurtz, for whom he acted at the School of Medicine during his illness. Soon after he had taken his degree he was promoted, after a brilliant competitive examination, to agrégé

Digitized by Google

of the Faculty, on which occasion he wrote a remarkable thesis on the action of soluble ferments on albuminoid substances. He was also Professor at the Municipal School of Chemistry. Dr. Henninger was the author of several works on biology and on chemistry, among which may be cited the Synthesis of Orcine, and another on Erythrite. He was also one of the coadjutors of M. Wurtz in his construction of his great Dictionary on Chemistry.

THE CHOLERA EPIDEMIC.

The cholera is at last in our midst, and though not unexpected, it has taken the Parisians by surprise. It cannot be said that they are terror-stricken, but they are in the state of excitement common to them in any great event, such as a revolution or a war. Cholera is everywhere the topic of conversation, and the newspapers are taken up with avidity. The disease is officially reported to have broken out in Paris on the 4th inst., and yet it is now known that several cases had occurred in and about this city almost simultaneously with the outbreak of the epidemic at Toulon and Marseilles, but the fact was kept a secret. The disease seems to be of a mild form, and it is not confined to any particular district, though the first cases that occurred were in a narrow filthy lane in the Faubourg St. Antoine, which is generally inhabited by *chiffonniers* and the most degraded specimens, morally and physically, of civilised society; but how it got there it is impossible to find out, nor yet in the majority of the cases that have since occurred in other parts can any direct connexion be found between them to account for its spread by contagion. All possible precautions are being taken to prevent the extension of the disease, and printed rules for the guidance of the public are posted up in every quarter. Among the measures prescribed are, of course, the most scrupulous cleanliness in and out of doors, and the thorough disinfection of everything that has been in contact with cholera patients. Water boiled for drinking and other personal use is enjoined, as it is now admitted that water is the most ordinary vehicle of the germs of the disease. Official reports of the number of admissions and deaths are daily published, and the following is that given to the 11th inst:—

	Admissions.	Deaths.
November 4th	3	2
,, 5th	9	6
,, 6th	10	5
,, 7th	37	12
,, 8th	70	Unknown
,, 9th	185	51
,, 10th	119	50
,, 11th	152	56

At Nantes there have been forty-five fresh cases since Wednesday, the 5th, to Monday, the 10th inst., and there have been twenty-two deaths from the disease during that time. The last report from Yport, dated the 9th inst., states that there were then only seven cases under treatment. After an absence of three weeks the cholera has reappeared at Toulon, where it is reported that ten cases occurred on the 10th inst., of which three died. The disease broke out in a charity school situated in a street where it had been raging to a great extent.

THE NEW DIRECTOR OF PUBLIC ASSISTANCE.

M. Cazelles, Prefect of the Bouches-du-Rhône, who was named as the successor of M. Quentin as Director of Public Assistance, having declined the honour, Dr. Peyron, Director of the Asylum for the Deaf and Dumb, has been appointed to the office.

Paris, Nov. 12th.

THE SERVICES.

Owing to the drain upon the Medical Staff Corps, nearly one-third of its entire strength being now in Egypt, and in anticipation of other emergencies, instructions have been issued for the formation of a Militia Reserve of 1200 men. To form this reserve ten men will be selected from each battalion of Infantry Militia, and when a battalion is called up for annual training the men joining the Militia Reserve of the Medical Staff Corps will be placed at the disposal of the principal medical officer of the district to which the regiment is to be attached, and will undergo a course of training in all the duties appertaining to the Medical Staff Corps.

RIFLE VOLUNTEERS.—5th Durham: Lieutenant Charles James Sutherland is appointed Acting Surgeon.—18th Middlesex: Clement Godson, Gent., M.D., to be Acting Surgeon.—2nd Volunteer Battlion, the Royal Fusiliers (City of London Regiment): Acting Surgeon William Joseph Atkinson resigns his appointment.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT an ordinary meeting of the Council on Thursday last, a resolution from the Committee of Management of the Combined Physicians' and Surgeons' Examining Scheme was considered. The resolution was to the effect that it be recommended to the authorities of the two Colleges to proceed as early as possible to the appointment of examiners in accordance with the provision of Part II. of the Scheme.

Mr. Erichsen asked what had been done respecting the preparation of the new Charter, and it was answered that a new Charter had been drawn up by the standing counsel of the College, and was awaiting the changes that might arise from the consideration of the Recommendations of the Association of Fellows. The Recommendations of the Association of Fellows were presented and read, and will be taken into consideration at an extraordinary meeting of the Council, which is convened for Wednesday next. At the same extraordinary meeting Mr. Heath's motion respecting the mode of election of president will be considered. Respecting the appointment of examiners under the Combined Scheme, it was agreed to appoint the examiners in Anatomy, Physiology, and Midwifery; and Mr. Marshall proposed that the examiners in Anatomy and Physiology on the Conjoint Board may be selected from the Members of the College as well as from the Fellows. The appointment of the examiners was deferred.

Mr. Marshall gave notice of motion that at the next meeting of Council he will move that it be considered whether the fee for the diplomas granted under the new Conjoint Scheme cannot be reduced.

Mr. Jonathan Hutchinson, whose diploma of Member is dated May 21st, 1880, and who passed his examination in November, 1883, was admitted a Fellow of the College.

MEDICAL NOTES IN PARLIAMENT.

IN the House of Lords on Monday, in answer to Lord Stanley of Alderley, Lord Carlingford stated that the managers of the school concerned had been written to by the Education Department respecting the death of Harriet Stocker from alleged over-pressure, and had been requested to give their view of the case, and to make whatever observations they wished upon it. This answer had not, however, yet arrived.

Quarantine.

In the House of Commons on Thursday, Dr. Cameron inquired of the Under Secretary of State for the Colonies whether it was true, as stated by a Madrid correspondent, that the authorities at Gibraltar have decided to impose twenty-one days' quarantine on all arrivals from Italy and France, counting from the day of departure, whether with clean bills or otherwise; and if so, whether, in view of the belief as to the uselessness of quarantine entertained and acted on by the Home Government, and the frequent remonstrances which this country had occasion to address to other nations regarding their quarantine regulations, he would instruct the authorities at Gibraltar to adopt precautions less at variance with the practice and policy of the United Kingdom.—Mr. E. Ashley replied that twenty-one days' quarantine was imposed on all arrivals from Italy. In the case of France, it was only imposed on particular vessels coming from French Mediterranean ports. The governor would be asked whether he could make some relaxation of the rule; but the Secretary of State was not prepared to require the local government to act on the opinions of the Home Government in such matters, in opposition to the very decided wish of the people there, and having regard to the peculiar position of Gibraltar.

Captain of Orderlies C. Cook.

In answer to Mr. Justin M'Carthy, the Marquis of Hartington said that the rank of Captain of Orderlies is retained entirely for the benefit of the late Army Hospital Corps, who did not elect to join in the new rank of quartermasters under the Warrant of 1881. For this reason it was not necessary that they should be specified in the Royal Warrant, as the preamble provided for them. The abolition of the title in no way affected the position or the emoluments of the officer referred to in the question. He continues to hold the same position in the Medical Department as he held before, and is not in receipt of a lower rate of pay than that drawn by the other officers of his grade of service before they accepted the terms of the Royal Warrant of June 25th, 1881. In that Warrant the officers who accepted the new rate now draw a higher rate of pay than the quartermasters. The fact is, a captain of orderlies is not worse off than formerly, but his brother officers become better off by accepting certain conditions.

Medical News.

UNIVERSITY OF CAMBRIDGE. — At a congregation held on the 6th inst. the following degrees were conferred:—

M.D.—Herbert Tyrrell Griffiths, Trinity.
M.B.—Charles Arthur Morris, Gonville and Caius.
B.S.—Charles Arthur Morris.

APOTHECARIES' HALL. — The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Nov. 6th:—

Barrett, W. Peard, Bunwell House, Cheltenham.
Bell, W. Howard, Myddelton-square.
Dagg, Trevor Augustus, St. Bartholomew's Hospital.
Farr, Ernest, Gloucester House, Barry-road, East Dulwich.
Jones, Herbert Charles Walter, St. Bartholomew's Hospital.

The following gentleman also on the same day passed the Primary Professional Examination:—

Jones, Herbert Josiah, Middlesex Hospital.

SIR LYON PLAYFAIR has been appointed President-Elect for the next meeting of the British Association, to be held at Aberdeen in September next.

A COPY in bronze of a marble bust of the late Dr. J. Marion Sims has been presented to the New York Academy of Medicine by Dr. H. Marion Sims.

THE Mayor of Leamington, in commemoration of his re-election, has presented the local hospital with a donation of one hundred guineas.

SUPERANNUATION ALLOWANCE. — E. N. Sison, medical officer of the eleventh district of St. Luke's Union, has obtained a superannuation allowance of £70 a year.

SANITARY INSTITUTE OF GREAT BRITAIN.—At an examination held on Nov. 6th and 7th, twenty-seven candidates presented themselves, eight as local surveyors and nineteen as inspectors of nuisances.

MR. GLADSTONE has recommended that a grant of £300 be paid from the Royal Bounty Fund to Mr. George Smith, of Coalville, as an acknowledgment for his great services on behalf of the brickyard, canal, and gipsy children.

SEAMEN'S HOSPITAL.—The work of erecting a new chapel and of laying down fresh drainage has been commenced at this hospital. The cost will, it is estimated, reach the sum of £8850.

SALOP INFIRMARY.—At the anniversary of the infirmary held on the 6th inst. at Shrewsbury, it was announced that a legacy to the institution of £9000 had been bequeathed by the late Mr. Henry Spence, of Shrewsbury.

IN consequence of the prevalence of small-pox in the city, the authorities of Durham University have intimated to the students that they can commence the Christmas vacation as soon as they have completed the forty-six days necessary to enable them to keep term.

SANITARY ASSURANCE ASSOCIATION. — At the ordinary Council meeting of the Sanitary Assurance Association, 5, Argyll-place, W., on Monday last, Sir Joseph Fayrer in the chair, it was arranged for four lectures to be given on sanitary subjects during November and December, to which admission will be free.

DEATH FROM BICHLORIDE OF METHYLENE.—At Bedminster on the 7th inst., whilst a dentist was complying with a patient's request to use his painless dentistry process, in which bichloride of methylene was used, he observed that the boy's head dropped, that he turned pale, and that he was gasping for breath. A restorative was administered, but without success, and a medical man was summoned, but before his arrival death had occurred.

ST. JOHN AMBULANCE ASSOCIATION.—Mr. John Furley, deputy chairman of the Association, opened the winter session at Sevenoaks on Friday evening, the 7th inst., Mr. Multon Lambard in the chair. Sevenoaks, though comparatively a small town, has done well as regards ambulance work. The second place out of London to form a centre, it has an organised ambulance corps, and material, such as stretchers &c., deposited for use at the railway station and other suitable points.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY. — At a meeting of the Medico-Chirurgical Society, held on the 5th inst., the following gentlemen were elected office-bearers for the ensuing year:—President: Dr. Henry D. Littlejohn. Vice-Presidents: Drs. David Wilson, J. Batty Tuke, and John Duncan. Councillors: Drs. George Hunter, J. Jamieson, Graham Brown, J. M. Cotterill, Rattray, A. Moir, Mr. Johnson Symington, and Dr. Macbride. Treasurer: Mr. A. G Miller. Secretaries; Drs. MacGillivray and James. Editor of Transactions: Dr. William Craig.

DEATHS DURING ANÆSTHESIA.—An inquest was held on the 10th inst. at Spitalfields on the body of a boy who had died whilst under the influence of ether administered at the Metropolitan Free Hospital for the purpose of performing an operation for bronchocele. The jury returned a verdict of death by misadventure. At Derby, too, on the 10th inst. an inquest was held on the body of a boy who died in the infirmary from paralysis of the heart immediately chloroform was administered. The jury exonerated the medical men from all blame.

LONDON HOSPITAL MEDICAL COLLEGE.—The subjects of the course of six lectures which will be delivered by Mr. Jonathan Hutchinson, the Emeritus Professor of Clinical Surgery, are as follows:—Monday, Nov. 24th, "On the Art of Note-taking and other Matters;" Wednesday, Nov. 26th, "On the Surgery of the Receiving Room;" Monday, Dec. 1st, "On Head Injuries, Hernia, and other Matters;" Wednesday, Dec. 3rd, "On Dislocations and Fractures;" Monday, Dec. 8th, "On the Treatment of Wounds," &c.; Wednesday, Dec. 10th, "On Retention Cases, Injuries to Viscera," &c. &c. The lectures will be delivered at 3 P.M. each day.

MEDICAL MAYORS.—The following members of the medical profession have recently been elected chief magistrates of their respective towns:—Arundel: Mr. Philip Hubbert, M.R.C.S., L.S.A. Bacup: Dr. W. J. Clegg. Blackpool: Mr. W. H. Cocker, M.R.C.S., L.S.A. Glastonbury: Mr. J. A. Bright, M.R.C.S., L.S.A. Grimsby: Mr. T. B. Keetley, M.R.C.S., L.S.A. Hanley: Mr. J. Charlesworth, M.R.C.S., L.R.C.P. Hartlepool: Mr. J. Rawlings, M.R.C.S., L.S.A. Honiton: Mr. J. C. Macaulay, M.R.C.S., L.S.A. Liskeard: Mr. W. Nettle, M.R.C.S, L.S.A. Southport: Mr. G. A. Pilkington, M.R.C.S., L.S.A. Tewkesbury: Mr. J. H. Boughton, M.R.C.S. West Bromwich: Dr. T. Underhill. Wilton: Mr. C. R. Straton, F.R.C.S.

LOWER THAMES VALLEY DRAINAGE.—The Local Government Board have announced their intention to hold an inquiry at Kingston-on-Thames on the 19th inst., with reference to the proposed dissolution of the Lower Thames Valley Main Sewerage Board, and to hear the applications of the constituent authorities seeking separation from that board. Sir Joseph Bazalgette has submitted his report on his scheme for the sewerage of the united district. It is proposed to collect the sewage of the various contributory places by sewers converging to a pumping station situated either on the east of New Malden, or on a still more eligible site near Sutton-common-road; there to be raised into a tunnel sewer, the dimensions of which will be 6ft. 6in. by 4ft. 4in., and through which it will be carried by gravitation, the sewer having a fall of nearly 3ft. to the mile, right away to a piece of land already provisionally secured at Crossness, lower down but immediately adjoining the metropolitan reservoir, there to be disposed of in conjunction with the sewage of London.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

ALEXANDER, FRED. WILLIAM, M.R.C.S., has been appointed Assistant Medical Officer to the Workhouse Infirmary and Schools, Mile-end Old Town Hamlet, vice Atkins.

BLUMER, W. PERCY, F.R.C.S.E., has been appointed Honorary Surgeon to the Monkwearmouth and Southwick Dispensary, vice James Murphy, M.D., resigned.

BROWN, WILLIAM PERRIN, L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for the Skircoat District of the Halifax Union, vice Scholefield.

CÆSAR, JULIUS, L.R.C.P.Ed., L.R.C.S.Ed., L.S.A.Lond., has been appointed Medical Officer for the Workhouse and Eastchurch District of the Sheppey Union, vice Bland.

CLOUGH, MORLEY EDDISON, L.R.C.P.Ed., M.R.C.S., has been appointed Government Medical Officer at Gympie, Queensland.

FRASER, T. A., M.B., C.M., M.R.C.S., has been elected House-Surgeon to the North Riding Infirmary, Middlesbrough.

GARMAN, JOHN COOPER, L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer for the Brewood District of the Cannock Union, vice Duce.

GELL, THOS. SILVESTER, M.D., C.M.Ed., M.R.C.S., has been appointed Medical Officer to the Hodgkinson Goldfields District Hospital, Thornborough, Queensland.

GIBB, WILLIAM, M.B., has been appointed House-Surgeon to Barnhill Hospital, Glasgow, vice Thos. S. Dunn, M.B., resigned.

GRIMSDALE, T. B., B.A., M.B., M.R.C.S., has been appointed Assistant Medical Officer to the Children's Infirmary, Liverpool.

HAXWORTH, WALTER, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the West Breton and Crigglestone Districts of the Wakefield Union, vice White.

LESLIE, WILLIAM BURNUP, M.D., C.M.Aber., has been appointed Medical Officer for Fetteresso Parish, Stonehaven, vice Edmond, resigned; also Medical Officer of Health of the Stonehaven Rural Sanitary District.

LITTLEWOOD, J. O., L.R.C.P.Lond., M.R.C.S., has been appointed Consulting Surgeon to the Walsall Cottage Hospital.

SHEARS, CHARLES H., L.R.C.P.Lond., M.R.C.S., has been appointed Assistant-Surgeon to the Liverpool Eye and Ear Infirmary.

STEWART, ROTHSAY C., M.R.C.S., L.S.A.Lond., has been appointed Assistant Medical Officer to the Peckham House Asylum, Peckham, S.E., vice Dr. W. G. Coombe, resigned.

TAYLOR, WILLIAM, M.D.Ed., L.R.C.P.Ed., M.R.C.S., Physician to the Glamorganshire and Monmouthshire Infirmary, has been appointed Medical Officer to attend the Workmen at the Llanishen Waterworks.

WATTIE, ALEXANDER, M.B., C.M., M.A., of Strathdon, Aberdeenshire, has been appointed Medical Officer for the Parish of Stronsay, Orkney.

WHOLEY, T., L.R.C.P.Lond., M.R.C.S., has been appointed House-Physician to the London Hospital, vice A. F. Peskett, M.R.C.S., L.S.A.Lond.

Births, Marriages, and Deaths.

BIRTHS.

DAWSON.—On the 5th inst., at Hyde-park-street, the wife of Yelverton Dawson, M.D., of twin-boys.

PRICE.—On the 6th inst., at Sloane-street, S.W., the wife of Robert J. Price, M.R.C.S., of the Middle Temple, of a daughter.

PRINGLE.—On the 4th inst., at Aberdeen-terrace, Blackheath, S.E., the wife of R. Pringle, M.D., H.M.'s Bengal Army, of a daughter.

RENDALL.—On the 9th inst., at Maiden Newton, Dorset, the wife of William Rendall, M.R.C.S., of a son.

SMITH.—On the 11th inst., the wife of Clement M. Smith, M.D., of Argyll Hall, Torquay, and St. Enoder, Cornwall, of a daughter.

MARRIAGES.

MITCHELL—DUNN.—On the 9th August., at Adelaide, South Australia, James Thomas Mitchell, M.B., of Port Adelaide, to Edith Mary, eldest daughter of the Hon. John Dunn, of Hackney, Adelaide.

STOKES—HINUBER.—On the 30th ult., at St. Thomas's Church, Lymington, Surgeon-Major Alexander Haldane Stokes, Medical Staff, to Mary Williamina Chaloner Hinuber, youngest daughter of the late Adolphus Hinuber, Esq.

DEATHS.

CHILCOT.—On the 11th September, at Wardell, Richmond River, New South Wales, James Chilcot, M.R.C.S., only son of J. W. Chilcot, Esq., of Southsea, after a few days' illness, aged 37.

HAFFENDEN.—On the 9th inst., at Holland-road, Kensington, Ada E., widow of D. A. Haffenden, F.R.C.S., aged 40.

HUNTER.—On the 11th inst., at Isleworth, Richard Henry Hunter M.R.C.S., aged 46.

KIDD.—On the 31st ult., at Hamilton, Bermuda, Leonard Kidd, Deputy Surgeon-General, Army Medical Staff, in his 55th year.

RIDSDALE.—On the 11th inst., at Endsleigh-gardens, Gordon-square, N.W., George Ridsdale, M.D., aged 69.

SIMPSON.—On the 11th inst., at Inverleith-row, Edinburgh, Magnus Simpson, M.B., C.M., youngest son of the late Sir James Young Simpson, Bart., aged 32.

VEITCH.—On the 10th inst., in London, John Toswill Veitch, M.D., of Brahrang, Warrington-road, Ipswich, late Colonial Surgeon, Penang, aged 67.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

TO OUR CONTRIBUTORS.

WE do not propose to publish this year a list of intending contributors to our volumes for 1885. The response to our annual circular has in the past been so liberal that we have with difficulty been able to keep pace with the supply of papers and communications with which we have been favoured. We shall be glad, however, to receive, for private record, the names of medical officers of public institutions, as well as of physicians and surgeons in private and general practice, who are desirous of furnishing us with clinical lectures and reports of cases of interest for our forthcoming volumes.

"IRRITATION OF THE SKIN FOLLOWING THE APPLICATION OF VASELINE AS A SURGICAL DRESSING."

To the Editor of THE LANCET.

SIR,—Some recent experiences induce me to write and confirm the opinion of Mr. A. W. Mayo Robson of Leeds, given, under the above title, in your issue of the 8th inst.—viz., that it may be "some skins present the same idiosyncrasy to preparations of vaseline as others do to any application of tar."

Since the time that vaseline has been in common use, both as a simple emollient and as a vehicle for various ointments, I have on several occasions convinced myself that it has had an irritating effect of no inconsiderable kind, amounting to the production of "severe dermatitis." From repeated observations I have made I am unable to come to a conclusion other than that certain persons do possess this predisposition or idiosyncrasy. I may add that I have witnessed similar results in connexion with simple benzoated zinc ointment. It may be that some of your readers have noticed that cutaneous ulcers have occasionally been rendered so painful by this latter ointment also that its use has had to be discontinued.—I am, Sir, yours faithfully,

Finsbury-circus, Nov. 10th, 1884. J. HERBERT STOWERS, M.D.

Anxious Enquirer.—We should be inclined to doubt the fact, and have therefore no explanation to offer.

Mr. Niven.—The first number of the "Chronicle" was noticed in our issue of the 1st inst.

TOBACCO.

To the Editor of THE LANCET.

SIR,—Amongst your numerous readers there must be several who are interested in the above subject. I should be very grateful if they would kindly acquaint me with the names of works on the subject, or any information referring thereto. I am, Sir, yours truly,

Sidcup, Kent. FRANK SHAPLEY, M.R.C.S.

EXTRACT OF MEAT.

Since the publication of our annotation on this subject in our issue for Nov. 1st, we have ascertained that the Liebig Extract of Meat Company actually use from 40 lb. to 42 lb. of lean meat to produce 1 lb. of their extract, instead of 34 lb., as stated by us.

L.R.C.P. thinks that when men receive their qualifications they should be informed of the necessity for registration, and of its advantages.

THE INDIAN CHOLERA COMMISSION.

To the Editor of THE LANCET.

SIR,—In your issue of Sept. 20th, received here by last mail, under the heading of "The Indian Cholera Commission," Surgeon-Major D. D. Cunningham gets brevet rank as Surgeon-General and Sanitary Commissioner with the Government of India, and has attributed to him the character and views of the actual incumbent of these senior appointments, Dr. J. M. Cuningham.

Dr. D. D. Cunningham is now Professor of Physiology and Pathology in the Medical College here, but was for many years associated, in carrying on cholera investigation, with Dr. T. R. Lewis, whose able paper on Koch's bacillus appears in your issue under comment.

The appointment by the Secretary of State of Drs. Klein and Gibbes to supersede the perfunctory arrangements of the Indian Government for continuing cholera investigation in this country gave some hopes that the subject would get the attention it deserves. It is now, however, understood that these gentlemen, after a short sojourn in Bombay, having exploded Dr. Koch's theory, are about to return home. If the object of their visit was only to upset Dr. Koch, an end apparently attained by Dr. Lewis, the result is not satisfactory to India, and whatever new theory they may have established it will be a matter of regret if they do not strengthen their position by personal acquaintance with, and careful investigation of, the numerous cholera localities throughout India. The origin of the disease is too mysterious to be demonstrated by a *veni, vidi, vici* visit to Bombay. I am, Sir, yours truly,

Calcutta, Oct. 13th, 1884. VIBRIO.

* In our annotation on "The Indian Cholera Commission," in THE LANCET of Sept. 20th, by an oversight, Dr. D. D. Cunningham, who was appointed a member, was confounded with Dr. J. M. Cuningham, the Surgeon-General and Sanitary Commissioner.—ED. L.

A RARE CASE.

To the Editor of THE LANCET.

SIR,—The case mentioned by Dr. P. W. Macdonald in THE LANCET of the 8th inst. under the above heading reminds me of a similar one.

A young lady aged about twenty-one years, the subject of asthma, was seen by me some time ago suffering then from incipient signs of phthisis of the right side; in course of time a little tumour formed on the front of the chest, between the third and fourth ribs, which soon broke, discharging a good deal of very unhealthy pus, it continuing for weeks and being aggravated by the patient coughing, when it had all the appearance of being pumped. Her health and surroundings improving under the use of the chemical food I stopped my visits; then, after about a month, I was asked to see her, as her mother said another abscess was forming. On examination I found my patient no worse as far as looks, strength, and auscultatory signs went; in fact, she was in better spirits, felt stronger, and free from fits of asthma. The place above-mentioned was still open, but discharging little, if any, pus, but on the posterior part of the same lung and over the ribs was a swelling, which in the course of a week or so I opened; this continued to discharge a good deal, being increased on coughing and while the lower one was open the top ceased. I now endeavoured to close the top opening, leaving the lower one to carry off the matter, but nature thought otherwise, and healed up the lower opening, leaving the top one open to this day. I should say that during all this time the patient got better, and though I have not seen her lately I often hear that she continues well and gets out on horseback, &c. I cannot give exact dates for the above facts, as I did not note them down, but it is clearly impressed on my memory.

I am, Sir, yours truly,

Ashburton, Devon, Nov. 11th, 1884. WILLIAM FRASER, M.B.

Nemo.—£1 1*s*. for each day of attendance at the trial. A medical man cannot claim a fee for detention on Sundays, not even for hotel expenses. For further details, consult THE LANCET of April 26th, 1884, and Taylor's Medical Jurisprudence.

Mr. F. D. Perrott had better consult our advertising columns.

CASES SIMULATING EMPYEMA.

To the Editor of THE LANCET.

SIR,—In your report of a discussion which took place at the Pathological Society on the 4th inst., on a case of caseous pneumonia simulating empyema, Dr. Lanchester is reported to have said: "No other condition than pleuritic effusion and this form of consolidation could give rise to bulging of the chest walls, displacement of organs, and the other physical signs." If he refers to page 200 of vol. xiii. of the Clinical Society's Transactions, he will find that I have there recorded a case of intrathoracic sarcoma in which all the signs of a fluid effusion into the pleural cavity were simulated. In this instance, as in the case reported by Dr. Hobson to the Pathological Society, several attempts were made to evacuate what, relying on the physical signs and symptoms, was considered to be an empyema.—Your obedient servant,

Queen Anne-street, W., Nov. 11th, 1884. H. P. DE HAVELAND HALL.

NEW VIEWS ON THE ACTION OF OPIUM IN CHOLERA.

THE following ingenious explanation of the efficacy of opium in cholera, based on the hypothesis that the disease is due to the presence of a bacillus, is given by Dr. Kispert in *El Genio Medico-Chirurgico*, Sept. 30th, 1884. He remarks that opium has a powerfully preventive action in cases of choleraic diarrhœa, and is the only remedy of avail in the most severe attacks. As to its *modus operandi* in cholera, he suggests three possible explanations:—1. Since opium obviously cannot have any direct action on the cholera bacillus, it may, by arresting peristalsis and exudation, produce such a modification of the intestinal contents that the bacilli are deprived of the conditions necessary to their development and vitality. 2 Koch has shown that the comma bacilli cannot exist in putrefying fluids containing the products of metabolism of other bacteria, especially of putrefactive bacteria. The arrest of the normal intestinal transudation by opium probably favours the development of putrefactive organisms, which thereby tend to exclude or destroy the comma bacilli. 3. A further hypothesis may be based on the researches of Metschnikoff (Untersuchung über die intracelluläre Verdauung bei Wirbellosen Thiere, Wien; und Untersuchung über die mesodermaten Phagocyton einiger Wirbelthiere.—*Biolog. Centralbl*, No. 18) of the part played by living cells of the organism—the "phagocytes" of the intestine, which, during the arrest of transudation by opium, may enter into a struggle for existence with the comma bacilli.

Mr. W. Eddowes.—We think the nurse cannot claim further remuneration; but the point is a legal one, which we do not undertake to decide.

Ajax.—Barnes, West, Duncan.

CLEARING TRACHEOTOMY TUBES.

To the Editor of THE LANCET.

SIR,—Having had a very considerable experience in the operation of tracheotomy, perhaps you will allow me to offer a few remarks on the above subject.

Most of the letters which have appeared in the medical journals and the lay press since Dr. Rabbeth's lamented death indicate on the part of their writers, as you justly observe, considerable ignorance of the nature of the problem to be solved. Tracheotomy and its after-treatment in most London hospitals appear to me to be too much a matter of tradition. In more than one hospital I know that the tubes and appliances are of the most antiquated description, and the after-treatment of these cases is frequently too little regarded. I would strongly advise every house-surgeon to read Mr. Parker's little work, "Tracheotomy in Laryngeal Diphtheria." It contains within a short compass practical instructions of great value, and all the greater because they are the outcome of a large and varied experience. Speaking from my own experience, I should say that in hospital practice it ought to be extremely rare to have a case of tracheotomy in which it could be necessary to apply the mouth for suction purposes either to the tube or to the tracheal opening. It indicates, as a rule, faulty methods and instruments. At the time of the operation, and before the tube is inserted, the wound should be kept open with dilators, and all obstructing membrane removed. This is best done by passing feathers into the trachea and twisting them round. The membrane is thus easily withdrawn, or so loosened and detached that it is expelled by the reflex cough excited. Should the membrane have extended into the main bronchi or tubes, or should much blood have been inhaled, and respiration seem to be impeded from these causes, then it is almost useless to suck the tube with the mouth. Some form of elastic tube should be passed down the trachea, and suction with the mouth or a syringe practised. The "tracheal aspirator" designed by Mr. Parker, and figured in his book, is a most simple and useful appliance for this purpose. It consists of a small glass cylinder, to one end of which is attached a flexible tube, and to the other a glass mouthpiece. The glass cylinder can be half filled with antiseptic wool, and thus all risk of infection is prevented. An alkaline spray greatly assists the solution and expulsion of membrane. In the absence of the tracheal aspirator, an elastic catheter may be used, or a piece of drain-tube. I have frequently used a combination of catheter and elastic tube. A few layers of antiseptic gauze or other material placed over the sucking end of the catheter make the proceeding practically safe. An easily worked syringe might be attached to the catheter, though the mouth is the most efficient suction machine. It is in the subsequent stages of a tracheotomy case that these last measures are chiefly demanded. But whenever during the course of a tracheotomy case the breathing becomes at all seriously impeded, the tube should be at once removed, the wound kept open with dilators, and the trachea feathered and sprayed.

The question whether such risk as Dr. Rabbeth ran need have been incurred depends very much on individual opinion, on the nature of the case, and on the conditions under which the operation was performed. I am decidedly of the opinion that a medical man is not justified in thus risking his own life, with all its possibilities, for the sake of a child suffering from a very fatal malady. I am quite aware that if everyone held this opinion and was actuated by it there would be fewer medical heroes and martyrs. Probably I may not always act up to this opinion, though I am not likely to change it.—Yours truly,

J. SCOTT BATTAMS,
Resident Medical Officer, East London Hospital for Children.

Nov. 4th, 1884.

Boaz.—The conditions of Fellowship of the Royal Society are scarcely matters within our special knowledge as medical journalists. Scientific distinction ought, of course, to be the only condition; but it must be admitted that the honoured letters F.R.S. are sometimes seen to follow names which with the greatest charity can scarcely be associated with advance in science. M.D.'s of foreign universities are never, as far as we know, admitted *ad eundem* to British universities; we cannot answer for Colonial ones.

Mr. F. D. Hamilton.—The handbill is beneath notice.

"HONORARY HOSPITAL SURGEONS IN BOMBAY."

To the Editor of THE LANCET.

SIR,—In your issue of Oct. 4th appeared an annotation under the above heading. As I was one of the honorary surgeons referred to, will you permit me to point out a few inaccuracies in the article? I ask this indulgence in self-defence, on your own motto, *audi alteram partem*.

1. Your article states that "the appointment of honorary surgeons to the Goculdas Tejpál Hospital has proved a complete failure." If this statement is correct, it is no less wonderful, seeing that in this city of Bombay we have about 120 non-official medical men in private practice from whom to choose honorary surgeons. Further, at a special general meeting of the Bombay Medical Union, this Union numbering about eighty medical men, held on Sept. 20th last, the following proposal was unanimously carried: "That the Bombay Medical Union regrets that the Government of Bombay should have deemed it advisable to discontinue the scheme of appointing honorary surgeons to the Goculdas Tejpál Hospital, and that a memorial be sent by the Union to Government, soliciting them to give a further trial to the scheme of employing honorary surgeons, as advocated by Dr. Cook, Principal of the Grant Medical College." All the speakers at that meeting were emphatic in declaring that the scheme of employing honorary surgeons in the Goculdas Tejpál Hospital had not failed. Still further, the Town Council, a few days ago, emphasised the opinion of the medical profession in Bombay by recommending the Corporation to reject the proposal of the Surgeon-General to appoint to the Hospital a highly paid medical officer of the Indian Medical Department, the hospital being not a Government institution, but a civic one. The only question on this subject that remains to be decided by the Corporation is whether to appoint paid or unpaid men. The source whence they are to be drawn is to remain unchanged—namely, from non-official medical men. As far as I can learn the views of members of the Corporation, the vote that will be passed will be in favour of honorary men.

2. You observe that the chief complaint made against the late honorary surgeons by Mr. Hojel was that "they come and go as they like." This report was made secretly and behind the backs of the honorary surgeons. As soon as it saw the light the honorary surgeons defended themselves in the local press and before the Corporation, and pointed out that the only irregularity of attendance which had occurred, or that could be proved, was the irregular attendance of Mr. Hojel.

3. You have also stated that Mr. Hojel communicated with the honorary surgeons "both verbally and in writing" in regard to the irregularity of attendance. I have long ago challenged Mr. Hojel to produce the writing referred to; but he has failed to do so, even after I publicly pronounced his statement to be untrue.

4. You say correctly that Mr. Hojel did "fix the hours of attendance of the honorary surgeons," but you do not say that he failed to fix the time of his own attendance. A daily record of the attendance of the honorary surgeons was kept for a period of five months; and I have been so much satisfied with my own regularity of attendance that I have submitted the daily hospital record of that attendance to the Corporation, to disprove the gratuitous charge which Mr. Hojel has made against me.

I am, Sir, yours faithfully,

Bombay, Oct. 24th, 1884. ROLAND BLANEY, M.A., M.B.

*** We consider the appointment of honorary surgeons to have been a failure, because the interests of the patients suffered from "the want of regularity and punctuality" in the attendance of these gentlemen, as stated in the Government resolution of Feb. 15th. This was so marked in the case of one of them that he was not reappointed, and new regulations were adopted to ensure regularity in future. We shall be glad to learn that these regulations have had the effect of protecting the patients from the neglect arising from want of punctuality, and that there is now no ground for complaint on this head.—ED. L.

Dr. C. Theodore Ewart.—The Secretary of the Aberdeen University Club is Dr. R. W. Burnet, 94, Wimpole-street, W.

Messrs. Mertens and Co.—We fear we shall be unable to find space for the article.

THE INCOME-TAX.

To the Editor of THE LANCET.

SIR,—I should like to know through your columns if there are many surgeons in the same plight as myself. I have received notice from the Income-tax Commissioners that I am assessed on £600 and shall have to pay £12 10s. Six hundred pounds is the very outside of my gross average receipt, and yet I have to keep an assistant, two horses, and a groom, besides purchasing drugs, bottles, instruments, &c. Is a surgeon not entitled to deductions for these as necessary expenses in carrying on his profession.

I am, Sir, yours truly,

Nov. 5th, 1884. IN MORSU DIABOLI.

THE LADIES' LAVATORY COMPANY.

DR. DAVID JOHNSON, calling attention to the institution of a lavatory for ladies in Oxford-street, writes as follows on the subject:—"In France, or say, Paris, as its great city, they manage these things better; or perhaps the general sense is less prudish; or gradually the caprice of common sense and common humanity has been less hampered by social proscriptions. The result in this particular, however, is a wiser freedom and official hospitality of this kind which we may well envy. The Ladies' Lavatory Company is a step in the right direction. The lavatory already constructed in Oxford-street is well and tastefully arranged, with a good entrance, convenient dressing-room, and every other requisite. I trust all who take an interest in this subject, as a mere matter of health, will visit this little establishment, and find themselves in duty bound to assist in organising a series of lavatories to be placed in well-considered centres of usefulness throughout the City, Strand, Oxford-street, and other great thoroughfares. It is a matter for consideration whether our vestry boards might not regard such conveniences for both sexes and all classes generally as falling within the scope of their administration, and out of parish rates provide institutions capable of being even a source of profit to the parishes in which they are located. Many things they do, and do well perhaps; but this, as a supplement to the suspicious iron cages, they have left undone. Fountains have been instituted here and there, as have cabmen's shelters and fire-escapes, and railway stations have been utilised; but the right kind of thing in the way of lavatories has yet to be put plentifully about, and near the places of popular resort."

"A NEW FORM OF SUTURE."

To the Editor of THE LANCET.

SIR,—Although in my opinion little good ensues from the public display of controversy between two correspondents, because each in endeavouring to set forth his own ideas and opinions not only ignores those of his opponent, but fails oftentimes to grasp them, yet I consider the letter from Dr. J. Ward Cousins to you, in reference to 'A New Form of Suture," requires to be answered. That gentleman says he has used a "very similar" suture, but after many trials has discarded it. Had it been exactly similar, under these circumstances, I myself might also discard it. Granting, however, that the practical application of such a thing proved troublesome at first, I do not at all agree with Dr. Cousins that such a principle of fixation of wounds, as suggested by me, is so hastily to be thrown aside by such negative assertions as he uses.

I adhere to my former expressions, that the ordinary means of closing wounds is objectionable, and that sometimes ulceration and strangulation of tissue ensue at the points of suture, even when skilful fingers manipulate. Where a wound, for instance, is deep and transverse to the axis of a muscle the degree of strain borne by the threads, if efficiently applied, is considerable, to which is often added inflammatory tension. The chief objections, however, to the thread suture are, the fact of its forming a foreign body, and that in a mechanical sense its mode of action is defective. A wound requiring sutures is generally a cavity, and, with more or less parallel walls when approximated, the scientific means of closing it would be a parallel and continuous force some distance from it, which would bring their entire surface into contact; and this could be best done by curved and sharpened wires such as I suggest. Thread as usually applied is an interrupted and partially misdirected force, binding up portions of the wound and leaving other parts unapproximated, which form nests for retrograding products.

I beg to refer Dr. Cousins to my first communication, where my expressions are qualified, and where I do not claim that such a suture as I suggest could supersede the old one, except in certain cases and situations; although if ever superseded, it must be by a principle here in question—viz., the closing of wounds by a force applied outside their cavity parallel to their walls, and ensuring universal and continuous apposition. With this object the suture may be of a form depicted by me, or, to ensure more easy introduction, each side may be separated with mechanism to keep them in situ.

Lastly, the application of a piece of cork or thread to the points is not essential, and were it so, would be easy and simple.

I am, Sir, your obedient servant,

Finsbury-park, N., Oct., 1884. JAMES MACMUNN.

AN APPEAL.

To the Editor of THE LANCET.

SIR,—You very kindly inserted an appeal for my father, S. F. Scarnell, L.A.C., in THE LANCET of Dec. 15th, 1883. Will you oblige him again this year? He enters his ninetieth year on Dec. 3rd, and has been bedridden ten years and three months. His sole income is £20 per annum, from the Medical Benevolent Fund. He practised for nineteen years at St. Osyth, Essex, and in Vassall-road, Brixton, for twenty-five years, where he was taken ill in 1865, since which time he has not been able to practise.

I am, Sir, yours respectfully,

19, Dante-road, Newington-butts, S.E., Oct. 31st, 1884. E. D. BAUERS.

For sanitary law it would be well to get the original Acts—viz., Public Health Act (1875), Water Act, Interment Act, Artisans and Labourers' Dwellings Acts and Amendment, Rivers Pollution Act, Food and Drugs Acts, Vaccination Acts, Canal Boats Act, Alkali Acts, Factories and Workshops Acts; and refer later, if necessary, to the Annotated Summaries by Smith, Husband, or Hime.

Mr. Barbarach.—We are not acquainted with any monograph on the subject.

ORIGIN OF TYPHOID.

To the Editor of THE LANCET.

SIR,—In the annotation on "Typhoid Fever in South Australia," in your last issue, you remark that the Central Board of Health are obliged to admit that it has been impossible hitherto to trace the cases to their origin.

Where typhoid arises in isolated places, or in fresh centres, apart from human infection, may I be allowed to direct the attention of my professional brethren, through the aid of your widely read journal, to a probable cattle origin of the disease. While practising in the Cape Colony I had many opportunities of observing cases of typhoid arise *de novo*, and in every case the presence of cattle manure infecting the air or water, or both, was the only explainable cause of the disease. Numerous instances were given in an article on the Genesis of Typhoid Fever in THE LANCET of Dec. 8th, 1883. My own belief is that typhoid is as essentially a cattle disease as cow-pox, communicated from cattle to man in the first instance, and afterwards spread by means of the excretions of persons affected with it. It is very difficult to prove the matter in densely populated countries; but, if true, evidence from the Colonies in its favour should be forthcoming. The question is, Does typhoid ever arise *de novo* where no cattle are present?

I am, Sir, yours truly,

Brighton, Nov. 10th, 1884. HENRY LAWRENCE, L.R.C.P.L., &c.

J. D. H.—A summary of Pasteur's experiments was given in our issue of Aug. 23rd last. A good, though rather brief, account of hydrophobia will be found in Quain's Dictionary.

"CORROSIVE SUBLIMATE AS A SURGICAL DRESSING."

To the Editor of THE LANCET.

SIR,—As I am in a position to controvert the interpretation placed on Sir Joseph Lister's case by Dr. Badcock, perhaps you will allow me to reply to his letter under the above title.

I recently excised a female breast for scirrhus. The wound was dressed with Hartmann's wood-wool, enclosed in his corrosive sublimate gauze, so as to form a large pad. When this was removed, on the third day, copious vesicles covered the whole of the skin under the pad, just as described by Sir Joseph Lister. I have never employed eucalyptol gauze; but the exact similarity of its action, as witnessed by Dr. Bantock, to that of corrosive sublimate tempts me to question whether the latter had not somehow entered into the manufacture of the sample used by him. I have since, in two or three instances, tried smearing the skin with an egg beaten up and rendered aseptic by sulphurous acid, and, so far, find that this entirely prevents the irritating effects of the sublimate. I should like to mention that the above case showed an additional peculiarity. When the dressing was first removed the skin beyond the limits of the pad was covered with a red, patchy, erythematous-looking rash. On the following day this had spread downwards to the thighs, and on the next day to the feet. Some also appeared on the arms and hands. It then faded slowly away. That this quasi-erythematous eruption was not ordinary erythema was proved, I think, by the healthy condition of the patient, by the aseptic course of the wound, and by the normal temperature.

I am, Sir, yours faithfully,

Norfolk-terrace, Bayswater, Nov. 2nd, 1884. HERBERT L. SNOW.

"LANCING THE GUMS."

To the Editor of THE LANCET.

SIR,—As I notice some doubts expressed as to the necessity for, and the efficacy of, lancing the gums of infants in your last issue, I beg to record my own experience in favour of it.

Some years ago a child of mine, a very fine boy, aged about one year, was, to us, very unaccountably ill at Bangalore, Madras, with feverish symptoms, hot head, constant crying, &c. He was then only, and well, nourished by his mother's milk. He was seen by the local medical practitioner, who, I think, never looked at his mouth, and nothing was done for him. By accident, on account of my own health, I was sent to Madras by the same practitioner, who was attending me, and, of course, my family went with me. Immediately on arriving there I sent for the local practitioner, for myself principally, who, on seeing the child, said, "Oh, he is suffering from his teeth," and straightway proceeded to lance the gums. The child improved from that time, and is now a strong young man. I am perfectly persuaded that had I not gone to Madras I should have lost the child.—Yours truly,

Nov. 11th, 1884. EXPERTO CREDE.

Reform Club.—The humorous letter of our anonymous correspondent who writes from the above address seems to show that an elementary knowledge of anatomy may lead to prudery. We commend to him and his friends the motto, "Honi soit qui mal y pense."

Dr. B. Beer (Vienna).—Yes, if not too long.

Mr. Welsford.—There is no novelty in the suggestion.

RESTORATION OF FUNCTION IN DIVIDED NERVES.

To the Editor of THE LANCET.

SIR,—In your issue of July 19th you mention two cases of divided median nerve resected, tied, and cured by M. Tillaux, one of a few months' standing, and the other of fourteen years'. In the first case sensibility began to return two days after the operation, and in the other twenty-four hours after.

Allow me to state that about ten years ago I published, in the *Edinburgh Medical Journal*, a case of excision of the elbow joint, where the ulnar nerve was completely divided accidentally. I immediately joined the ends by transfixing with a catgut thread. There never was any suspension of either sensation or motion in any of the parts supplied by the divided nerve; and at that time I called attention to the extraordinary fact that a divided nerve, if at once brought into juxtaposition, would carry on its functions before there had been any organic union at all, just as a broken telegraph wire would convey the electric current if brought into apposition without being soldered. This is, as you have observed, certainly a new departure in our views of the functions of nerves, and I humbly claim to have been the first to have brought this interesting fact before the profession. The restoration of function was not immediate in M. Tillaux's two cases, and this I account for by the nerves divided being toned down even in their conducting power by want of use. We can scarcely suppose that the restoration of nerve function in the second case recorded was owing to organic union, as it appeared next day; all the more so if studied in the light of my own case, where it was restored immediately after the operation.

I am, Sir, yours truly,

Oct. 18th, 1884. JAMES P. BRADWELL, M.D., L.R.C.S. Edin.,

"M.B. EXAMINATION, UNIVERSITY OF LONDON."

To the Editor of THE LANCET.

SIR,—Observing in your last issue the questions proposed by a correspondent, I turned to my bookshelves for information respecting "unilateral hæmatokolpos." The first four English text-books referred to do not so much as mention the condition, and I could find no allusion to it in Quain's Dictionary. I therefore began to think it would be very unjust if a candidate for a pass should lose one-sixth of his marks through ignorance of "the anatomy and treatment" of such a case. But I looked further, and lo! in vol. x. of Ziemssen's Cyclopædia I found an allusion to such a condition in a few lines, which just suffice to show how rare it is. I next found a paragraph about it, though under a different name, in a Scotch manual which, I have heard, is strongly recommended to his class by one of the examiners. I am also assured, but have not the book at hand to refer to, that the answer wanted is to be found in the same examiner's volume of Clinical Lectures.

I am, Sir, yours faithfully,

Nov. 8th, 1884. A LONDON TEACHER.

Accoucheur.—There is no remedy in the present state of the law. The only course likely to lead to a remedy would be to refuse certificates in such cases, and so compel their investigation by a jury. But this would be a painful procedure on the part of any medical man.

R. N. J. is referred to an article in THE LANCET of Aug. 23rd last.

Dr. Robert Fowler.—If possible, next week.

THE LIBRARY OF THE COLLEGE OF SURGEONS.

To the Editor of THE LANCET.

SIR,—On going to the College of Surgeons this afternoon I was disappointed to find the library closed, and on inquiry I learnt that it was shut every Saturday at 1 P.M. Now, as Saturday afternoon is the only time that a large number of young medical men, like myself, have the leisure for uninterrupted reading, it is somewhat hard upon us to be denied this privilege. I understand the Royal College of Surgeons to be a comparatively wealthy corporation, apart from the fact that they have recently been left a legacy of nearly a quarter of a million of money. The expense of keeping the library open on Saturday afternoons would involve at most only a few pounds a year, and the benefits that would accrue to members of the College would, I am sure, be incalculable. They may, perhaps, now that their attention has been drawn to it, consider this proposal. I am, Sir, yours truly,

Nov. 8th, 1884. A MEMBER.

WIRING THE PATELLA.

To the Editor of THE LANCET.

SIR,—I have found the same difficulty in passing the wire through the second fragment as Mr. Ogier Ward seems to have met with in the cases he reported in your issue of Nov. 1st; and like him I have had a trochar and cannula made, with a bradawl point, so that the cannula being left behind in the bone after the bradawl is withdrawn the wire can be readily passed. I showed this instrument at a medical meeting at Bath in July last. I now write to direct the attention of surgeons who may be contemplating wiring the patella to the practical usefulness of this instrument.—I am, Sir, yours faithfully,

Clifton, Nov. 10th, 1884. NELSON C. DOBSON, F.R.C.S.

Medical Diary for the ensuing Week.

Monday, November 17.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10½ A.M. each day, and at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.
ST. MARK'S HOSPITAL.—Operations, 2 P.M., and on Tuesdays at the same hour.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M
MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Carrick: The Manufacture and Uses of Koumiss in Russia. (Postponed.)—Dr. Markham Skerritt (Clifton): The Conduction of Physical Signs in Diseases of the Lungs.—Mr. Noble Smith will show a case of cured Meningocele.

Tuesday, November 18.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 P.M., and Thursdays at 2 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Percy Kidd: Fatal Hæmoptysis from Bronchial Ulceration.—Dr. Carrington: Addison's Disease, with Cancer of the Liver and Supra-renal Capsules.—Dr. Norman Moore: New Growth in Stomach of a Child.—Mr. Sutton: Uterine and Ovarian Disease in Animals and Birds.—Mr. Knowsley Thornton: Hydronephrosis caused by Papillary Growths and Calculus.—Mr. Hopkins: Bones from a Case of Ataxia.—Mr. Treves: Two Specimens of Tumour of the Soft Palate.—Mr. Lane: Fracture of First Rib (card).

Wednesday, November 19.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.—Ophthalmic Operations on Tuesdays and Thursdays, at 1.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1½ P.M.—Skin Department: 9.30 A.M., on Tuesdays and Fridays.
ST. THOMAS'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.
LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.
GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations 2½ P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour.—Skin Department: 1.45 P.M., and on Saturday at 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M.

Thursday, November 20.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—1½ P.M. Surgical Consultations.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.
NORTH-WEST LONDON HOSPITAL.—Operations, 2½ P.M.
SOCIETY FOR THE ENCOURAGEMENT OF ARTS, MANUFACTURES, AND COMMERCE.—Opening Meeting, 8 P.M. Address by Sir F. Abel.
HARVEIAN SOCIETY.—8.30 P.M. Mr. Thomas Bryant: The Mode of Death in Acute Intestinal Strangulation and Chronic Intestinal Obstruction.

Friday, November 21.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1½ P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 2 P.M.
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.
SOCIETY OF MEDICAL OFFICERS OF HEALTH.—7.30 P.M. Mr. Alfred Spencer: Noxious Trades.

Saturday, November 22.

The "Bowman" Lecture

ON THE

RELATION OF CERTAIN DISEASES OF THE EYE TO GOUT.

Delivered before the Ophthalmological Society of the United Kingdom, Nov. 18th, 1884, by

JONATHAN HUTCHINSON, F.R.S.

GENTLEMEN,—At the request of your Council I have the honour this evening to deliver the first "Bowman" Lecture. This lecture has been instituted with the design of gratefully commemorating the services of Sir William Boman to science, and more particularly those which he has rendered to this Society in his capacity as its first president. It is intended that the lecturer shall on each occasion undertake the investigation of some special subject in connexion with ophthalmology. I do not think that any more appropriate method could have been devised by which to pay respect to one of our very foremost workers. For myself, I can only say that I feel deeply the responsibility of the yet very agreeable duty which has devolved upon me, and could heartily wish that your Council had selected someone more capable of doing it justice. Having made this personal apology, I feel, however, that I shall best honour the name of Bowman by trying to imitate the example of his life, and proceeding at once, to the best of my ability, to deal with the subject in hand.

I take for the subject of my lecture the relations which exist between certain Diseases of the Eye and Gout. We shall have to classify several different forms of disease—for the most part, but not exclusively, inflammations of the iris—to describe their peculiarities and to examine the evidence which is forthcoming as to their real connexion with gout. The inquiry is an important one, for a gout taint is an extremely common occurrence in a large proportion of the British population. The investigation is also in many of its ramifications one of great intricacy and difficulty. Certain facts we shall, I trust, be able to establish with clearness; but respecting many others we shall not be able to get further than the stage of more or less confident inference. I had at one time intended to bring before you a good deal in the form of attempted proof—that is, of statistical tabular statements of fact. I have found, however, in the preparation of the lecture that the time at my disposal will not permit of more than a brief sketch of the whole subject, and I shall therefore, on compulsion, spare you much of the detail. It is, however, only just both to you and to myself to state that my arguments and assertions this evening will be based upon the careful examination of a lengthy series of recorded cases. A large part of these will be found given at length in vols. vii. and viii. of the Ophthalmic Hospital Reports, and the remainder I have in type before me, although not yet published.

Definitions of Gout and Rheumatism.—Before we proceed to inquire whether gout may be deemed to be the cause in some instances of such diseases as hæmorrhagic retinitis, recurring iritis, glaucoma, and others, it may be well to state that I wish to keep a clear distinction between gout and rheumatism. This distinction is in practice often very difficult, and sometimes quite impossible to draw, but for all purposes of accurate clinical pathology we must insist upon its existence. By gout I shall mean all states of health which are, whether directly or remotely, connected with the accumulation of lithate of soda in the blood as the result of overfeeding or defective assimilation.

Under the laws of inheritance of morbid tendency it may easily be the fact that a person may feel the effects of this condition in his parents, who may yet himself never exhibit it. We may have a form of inherited gout which is not associated in the patient with either lithiasis or lithæmia. Hence, as I shall have to show presently, some very peculiar forms of morbid action.

Thus it may perhaps be conveniently laid down that there are two fundamental conceptions of what gout is. They are not antagonistic, but rather in mutual coexistence. In practice the two methods of influence constantly modify each other.

What I may call the primitive conception of gout regards it as due to a state of the blood induced in part by errors in feeding, and in part by defects in assimilation and depuration. It has regard to the food, to the digestive power, to habits as regards exercise, and the integrity of the kidneys. In this form of dietetic or humoral gout the stage of lithæmia is essential, and the final product of deposit of urates in the tissues is almost equally so. We must, however, seek a wider vision than this. As an introductory stage to such wider view let us imagine the condition of a man who many years ago was subjected for a long period to the ordinary causes of primitive or humoral gout, but who for a considerable series of years has carefully avoided them. In such a person it is easy to see that although his blood may have been long kept free from excess of urates, yet, as the consequence of conditions of long duration in the past, his tissues may have received modification, and may be prone still to suffer in a peculiar manner when exposed to the ordinary exciting causes of disease. In particular they may be liable to grow old on a peculiar type. Not only are his tissues in general modified, but those of his nervous and vascular systems have probably been especially influenced. Hence the power of control over any process of inflammation, by whatever cause it may have been initiated, is peculiar and effective. If such a man sprain a joint it will not recover in the way it would have done had he never had gout, yet the joint may nevertheless be very far from assuming a typical gouty state. There may be no tendency whatever to the deposit of urates. Now, let us take another step in the attempt to give reality to our conceptions of the hidden influences under which the everyday phenomena about us are produced. Let us imagine that such a person as we have supposed—one who has suffered severely and through many years from humoral gout—becomes a parent. His offspring will inherit his tissues, his tendencies as regards digestion, kidney excretion, skin elimination, and all the rest. These will, no doubt, give a greatly increased proclivity to common typical gout should the cause of it come into play. They may, however, do much more than this. They may render their subject liable—quite independently of exciting causes, or with but little help from them—to forms of inflammation or of degraded nutrition, which are not unequivocal gout, but which are yet the direct consequence of it in his predecessors. The modification which is here inherited is, I suggest, of the tissues and not of the blood, though it is obviously very easy that the two may complicate each other. The subject of tissue modifications from inherited gout may easily become the victim of humoral gout as well.

Inherited Gout.—It is clear from this argument that we must be prepared to see inherited gout assume very different forms from those to which we are so well accustomed to in the primitive type. Permit me now to suggest that it is the clinical, or rather the social, fact that a not inconsiderable proportion of the well-to-do classes of the British population are born under the conditions which I have been supposing. The number of those who are the descendants of parents who have suffered from humoral gout is very large indeed, and, especially in our large towns, it is by no means restricted to the educated classes. We must be prepared, then, to encounter, not unfrequently, peculiar types of morbid action which derive their peculiarities from this association. It is the duty of the clinical investigator to carefully examine the evidence which is forthcoming as regards each before he admits its claim. Certain diseases of the eye for which this claim is with more or less confidence put forward will form part of our topics for discussion this evening. It may, perhaps, facilitate matters if I express at this stage the belief that most of the varieties of what is called rheumatic gout stand in this relation to true gout. This list would include lumbago, sciatica, neuralgia, crippling rheumatism, arthritis deformans, osteo-arthritis, many forms of iritis, and many cases of glaucoma. I by no means wish to suggest my belief that any one of these is in all cases in some degree dependent upon the inheritance of gout. Some of them are doubtless in not a few instances purely rheumatic, and this admission renders it desirable that I should say two or three words as to what our conception of rheumatism ought for the most part to be. Let me then hint that from our primitive idea of rheumatism I should like to exclude all causes having reference to food or assimilation, and to count only those which

Digitized by Google

regard climate and weather, and especially exposure to cold and damp. The rheumatic diathesis, like that of gout, may become ingrained, and at the same time modified by hereditary transmission, and in this connexion it is easy to overlook its original causes, and even to believe that it may begin spontaneously, or in consequence of other influences than the true ones. The hereditary diathesis of rheumatism (arthritic susceptibility to weather) may easily coexist with that of gout (arthritic susceptibility to diet), and each of them or both together may combine in endless variety with other forms of morbid tendency. It follows that we have to study many hybrid or mongrel types of disease in more or less close connexion with them.

"Hot Eye," Irritable Eyes, Quiet Gout, &c.—There is a condition to which, for want of a better name, I have for long been in the habit of recognising as "hot eye." It is one of the many curious phenomena which attend quiet gout. I use the term "quiet gout" as distinct from acutely paroxysmal gout. In families liable to gout, for one person who becomes the subject of acute attacks of podagra, what is known as unequivocal gout, there are often half a dozen who are the subjects of minor symptoms which denote a similar tendency. In them the tendency never rises to sufficient height to induce a severe and characteristic paroxysm. They are nevertheless liable, after taking beer or wine injudiciously as to quantity or quality, to experience slight pricking pains in the joints, attended by lithic acid in the urine and other unmistakable signs of the diathesis. In many these symptoms occur in such invariable association with the causes suggested, that it is not possible to doubt as to their nature. The liability varies with the weather and time of year, and it often ends, unless precautions are taken, in a sharp attack in the great toe. The terms "suppressed gout," or better, "undeclared gout," are often used in reference to it; but since it is simply a minor form of the disease not in any way suppressed, and certainly not to trained observers undeclared, I prefer the term "quiet." Amongst the frequent occurrences which denote its presence are repeated short attacks of congestion of the eye. Usually one only is affected, but sometimes both. The conjunctiva becomes red, and the eyeball feels hot, and pricks, as if sand were in it. The attack may come on within half an hour of the meal which has disagreed, and it may last a few hours, or a day or two. Sometimes, owing to interference with the ciliary muscle, vision is slightly dim, and all attempts at accommodation are usually painful. Those who are liable to hot eye not unfrequently in the end suffer from iritis; indeed, it is not unfrequently an introductory stage to that disease. On the other hand, many are liable for years to very frequent attacks of it without apparently any risk of its assuming more serious proportions. In the intervals of the attacks the eye is usually quite well, and it is indeed its definitely paroxysmal character, its sudden development, and very complete and rapid disappearance, which especially mark its arthritic relationship.

In connexion with this subject it may be noted that not unfrequently those who suffer from unequivocal gout experience shoots of sharp pain in the eyeballs, the nature of which they well understand. A man, William B——, aged fifty-four, who had suffered much from gout, and whose father and four of his father's brothers had all had it, complained much of this kind of pain, yet he had never had iritis. When he was gouty he said he frequently had "darts of pain through the middle of each eyeball," and occasionally across the bridge of the nose.

A further practical note I must ask leave to make. It is to the effect that many cases of irritable hyperæsthetic and easily tired eyes in young persons are in association with inherited gout. I feel sure that in some of these cases we are in the present day in danger of pushing the recommendation of spectacles to an excess. Some slight degree of hypermetropia may be detected, and it is assumed to explain the irritability of the eye. Yet glasses do no good, and, in fact, only increase the irritation. In such cases, very often, the real malady is inherited gout.

Transverse Calcareous Bands of the Cornea.—I must admit, in the commencement of our investigation, that little or no evidence exists as to the deposit of urate of soda in any of the structures of the eye. I doubt whether it has ever been proved in any single case, although several observers have suggested its presence. I trust, however, that we are long past the stage of belief which regards such deposit as essential to a gouty inflammation. The nearest approach to proof of gout deposit has been made probably in the case of what are known as the transverse calcareous bands in the cornea. Sir William Bowman, in the year 1848, was, I believe, the first to publish cases of this kind, but the earliest case had been observed by Mr. Dixon. Valuable information respecting the disease has recently been collected and studied by Mr. Nettleship. I believe I may fairly sum up the present state of our knowledge by saying that no one has yet proved that the salt deposited is that of gout. It is usually calcareous. The disease occurs in persons very likely to suffer from gout, and sometimes with a gouty history, but we are not as yet justified in holding that this earthy deposit is in direct connexion with that diathesis.

Arthritic Iritis.—It will be admitted without dispute from anyone that there are several forms of iritis which are arthritic in their origin—in other words, they occur to those who are liable to attacks of inflammation of joints, and the inflammations of the eye occur under conditions similar to those which excite the inflammations of the joint. Both are in some cases prone to occur in an acute but transitory attack. Both are very apt to recur after periods of complete immunity, whilst in other cases both may assume a chronic, persisting, and destructive form. With such features of similarity we are justified in assuming, as indeed is done by all authors, that they are due to the same causes. The problem which I have to consider to-night is whether these causes belong to gout or to the rheumatic class; whether they are sometimes the one and sometimes the other; and, lastly, whether they are not in some cases of a hybrid or mixed nature. Permit me briefly to state some of the peculiarities which are to be observed in different types of arthritic iritis; and to ask respecting each what evidence we possess which would connect them with the tendency to gout. Let us take first the common form in which the iritis occurs in acute transitory paroxysms. Of this, good typical examples will be in the memory of us all. Its subjects are usually men, and often of vigorous health, and past middle life. The iritis scarcely ever affects both eyes at the same time, but occurs first to one and then to the other, sometimes keeping to the same eye during several successive attacks, and then leaving it to assail its fellow. The attacks are often acute, beginning very suddenly, and attended with great pain. When they subside, they subside completely, and leave the eye without the slightest degree of irritability. The duration of the severity of an attack may vary greatly at different times in the same patient. The tendency to form adhesions is extremely great. It is very remarkable how in most cases of this class the disease restricts itself to the iris and shows no tendency to disorganise the globe. Thus, a patient in whom, in consequence of repeated attacks, the pupils may be occluded, with the exception of mere pinhole apertures, may yet continue to enjoy very fair sight. I by no means wish to imply that this is usually the case. The case of Dr. Curry, as recorded by himself in the Medico-Chirurgical Transactions, is a good type form of this disease. Dr. Curry had suffered much from true gout. I may cite, however, as another good type illustration of this class, that of a gentleman whose friendship I had the privilege to enjoy during a long period of my early life. He was a florid fair complexioned man, of vigorous habits, a large eater, and through life accustomed to drink beer. He inherited rheumatism, but there was no known history of gout. He had suffered in boyhood in consequence, as he believed, of too free bathing when hot, from rheumatic fever. When I knew him first he was about forty-five, and from that time onwards to his death, at the age of sixty, he had a variety of arthritic complaints—lumbago, sciatica, chronic arthritis of the knees and other joints, and recurrent iritis. Both his pupils were closed with the exception of very small apertures, through which, however, he still continued to see enough to follow an occupation in which everything depended on good sight. I attended this gentleman year after year, usually in the early part of February, for most severe attacks of iritis, never affecting both eyes at once. He was benefited by large doses of iodide of potassium and the free use of blisters. At length his attacks ceased to occur, and during the ten years preceding his death I believe he had not had any. I made a post-mortem examination of his body, and found no proof of gout. His knees contained loose cartilages, and there were patches where the articular cartilage was wearing away, but there was no urate of soda.

I have the record of a considerable number of cases in which the liability to these recurrent forms of iritis occur

Digitized by Google

in those who were the subjects of unequivocal gout. But there were a far larger number in which the concomitant symptoms were of rheumatic arthritis and not of true gout. The question remains, however, whether this form of rheumatic gout, although unattended by lithate of soda deposit, be not in reality a hybrid disease possessing, in addition to an unquestionable share of rheumatism, an admixture also of gout tendency. The infrequency of the disease in women, the age, the habit of body and the mode of life of those who are usually its subject, seem to me to strongly support this view. So does also the extreme severity of the attacks, and their rapid and complete subsidence, when once the point is turned. When this form of iritis does occur to women, it is never, I think, so acute or so paroxysmal as in men; and it almost always happens to those whose relatives have suffered from gout.

Various Forms of Arthritic Iritis.—Next to this form of recurrent iritis, and including perhaps some of its examples, I have to mention the iritis which occurs in connexion with gonorrhœal rheumatism. All observers will admit, I think, that iritis associated with ordinary rheumatic fever is infinitely rare. So also is it in connexion with that type of arthritis to which the name of crippling rheumatism may be given—in other words, iritis in association with either acute or chronic rheumatism is a thing that we scarcely ever observe. In men, however, the rheumatic affections, whether acute or chronic, which are induced by gonorrhœa, are not unfrequently accompanied by iritis. This iritis is less distinctly paroxysmal and much more liable to persist and be destructive than the case in the form which I have just described. My explanation of this is easy. The reason why gonorrhœal rheumatism so often causes iritis is because it occurs usually in the subjects of inherited gout.

A third form of arthritic iritis is one which affects women more frequently than men, which not unfrequently attacks both eyes at once, which is apt to spread to the ciliary region and choroid; to persist and to prove destructive. In a very considerable proportion of the women who suffer from this form there is a history of gout in former generations.

Another group of arthritic iritis might be constituted of cases in which the malady happens to young patients, and proves but slightly, if at all, liable to recur. These single attacks of iritis without history of gonorrhœa or syphilis, and occurring in young persons, usually, I think, affect the male sex, and almost always there is the history of gout in relatives.

I must just mention, in order to complete my classification, although it is but of little clinical importance, the group of cases in which iritis occurs in association with glycosuria. In these, according to my experience, the patient is almost always the subject of gout also.

To sum up, then, I would say that although in many individual cases of arthritic iritis there may be no proof of liability to gout in either the patient or his relatives, yet the tenour of the evidence in general is in favour of the conclusion that when iritis occurs there is in reality some gout complication. The more purely and definitely is the case one of rheumatism, and the less the probability that iritis will happen. When iritis occurs the complications are almost invariably those which suggest what we call rheumatic gout rather than rheumatism pure and simple; that the smaller joints are often affected and nodi digitorum present, whilst sciatica, lumbago, and neuralgia are frequent complications. I have elsewhere tried to prove that gonorrheal rheumatism occurs in nine cases out of ten to those who inherit a gouty constitution, and that it is chiefly this inheritance that gives the proclivity to it. I cannot stop now to recapitulate the evidence on which this belief rests; but if it be trustworthy, it offers an explanation of the fact that iritis is so frequently met with in association with this type of rheumatism.

In certain cases of iritis with arthritic associations a very peculiar condition is observed. I allude to the filling of the anterior chamber with a soft gelatinous jelly-like mass. This material, which produces an appearance most alarming to the uninitiated, concealing the pupil and suggesting entire destruction of the cornea, is susceptible of very rapid absorption, and may, in the course of a very few hours, clear right away. I believe that in some cases of syphilitic iritis this peculiar form of appearance has been noticed; but if I were to speak from my own experience, I should cite it as a symptom very strongly indicative of gout. I would make the same remark, though with less confidence, respecting the rare cases of iritis complicated with hæmorrhage.

Statistics as regards Arthritic Iritis.—My report on arthritic iritis, published in the *Ophthalmic Journal* of 1872–74, contains the narrative of 104 cases which are suitable for our present purpose; for various reasons I omit a few on account of doubts as to their nature or imperfections as to the details. The report comprises cases of all varieties in which either rheumatism or gout, or the two together, were supposed to have been the causes of inflammation of the eye. They were collected from my note-books, both from hospital and private practice, up to the date mentioned. It is right to state that at that time my opinions as to the influence of true gout were less advanced than they are at present, and that my knowledge as to the means of recognising it was also less. The notes of many of the cases had been taken some years before they were published, and thus certain inquiries, which I should now carefully make, were unfortunately omitted. On this account I have no doubt that we must consider that the report does not show the influence of gout so strongly as it would have done had the cases been taken with better knowledge. Out of the 104 cases, I find a positive history of gout having occurred in the patient in only eighteen cases, and only in twenty-nine was there the history of positive gout in near relatives. It is to be observed, however, that these numbers take cognisance only of what has been termed "unequivocal gout"—namely, of those in which an unmistakable attack of inflammation in the great toe or other single joint had unquestionably occurred. It omits altogether the much larger number in which the gouty tendency had remained undeclared or had been manifested only in what we may term its quiet form. Any one who will examine for himself the narratives to which I refer will, I feel sure, agree with me in this opinion. In a very large proportion there was, I think, good reason for believing that a taint of gout existed where the narrative mentions rheumatism only; the arthritis had constantly been of the chronic type, and had very frequently presented exceptional conditions. If we may count such maladies as sciatica, lumbago, neuralgia, nodi digitorum, gonorrhœal rheumatism, rheumatic gout when affecting the smaller joints, as being for the most part indications of gout rather than of pure rheumatism, we shall then find that facts at any rate suspicious of gout are present in nearly all the cases. It is, I think, decidedly exceptional for rheumatism pure and uncomplicated to show any tendency to attack the tissues of the eye. Iritis in conjunction with rheumatic fever of the ordinary form is almost unknown, and even in cases in which patients suffer from repeated attacks, as is sometimes seen, the eyes usually remain free. So soon, however, as changes of type occur, the disease showing a tendency to attack the smaller joints, or to affect only single joints, or to pass into the chronic form, then we get the liability on the part of the eye to suffer. On this point my own experience is quite in accordance with that previously expressed by an acute and zealous clinical observer, the late Dr. Fuller. Dr. Fuller in his first edition, speaking of rheumatic gout, stated that in 11 out of 101 cases which he had tabulated when medical registrar to St. George's Hospital, the eye had suffered more or less severely, and in 14 out of 193 cases which had subsequently been under his own care in the hospital. In a second edition, he stated that he had so far modified or developed that opinion, that he had come to believe that many, if not all, of the cases in which this complication occurs were examples of obscure gout or else of gonorrhœal rheumatism, adding, "This at least is certain, that since my attention has been specially directed to this question, I have been enabled to find a gouty or venereal [meaning, I think, gonorrhœal] taint in every case in which the eye has been inflamed in connexion with presumed rheumatic gout." This is strong testimony, stronger certainly than I am prepared to give, but I doubt whether it much exceeds the truth. Among other authors who have distinctly recognised gout as a cause of diseases of the eye, and appear to have referred a considerable proportion of those diseases, when arthritic, to gout rather than to rheumatism, I may mention Dr. Jacob, Mr. Weller, Mr. Middlemore, Dr. Copland, and perhaps Mr. Wardrop. Mr. Middlemore goes so far as to think that he has seen in one or two cases the pupil occupied by calcareous concretion of a gouty nature. None of these observers have, I think, recognised any other special disease as connected with gout than recurrent iritis. Almost invariably I find sclerotitis put down as rheumatic.

(To be concluded.)

CHOLERA.

BY MAX VON PETTENKOFER, M.D.,
OF MUNICH.

(*Continued from page 864.*)

THE further one investigates the drinking-water theory the more and more improbable does it appear. Robert Koch, too, the famous bacteriologist, has hitherto failed to substantiate the drinking-water theory, and I feel convinced that the time is not far distant when he will own that he has gone in the wrong direction. Koch has succeeded in finding the comma bacillus in a water tank in a region where cholera was prevalent. I have the greatest respect for this important discovery, not as a solution of the cholera question, but only as a very promising field for pathological, not epidemiological, inquiry. It must be remembered that cholera was already prevalent in the neighbourhood of the water tank from which Koch obtained the bacillus. Now, this tank was used not only for drinking purposes, but also for bathing the person and washing clothes, as Koch himself admits. According to my view the comma bacillus must have been present in the water. It had not been shown, however, that the bacillus was in the water before the outbreak of cholera. Koch is of opinion that all the bacilli in the water tank could not have come from the washing of clothes of cholera patients, but must have partly been derived from multiplication, yet he forgets that, as he himself has shown, the meat broth in which the bacilli grow must not be too dilute. It would have been interesting if Koch had estimated the strength of the nutritive material in the water tank. But what chiefly contradicts the doctrines of the contagionists is the simultaneous disappearance of the cholera on land and the cholera bacillus in the water-tank. If it were really true that every case of cholera, the first as well as the last in an epidemic, had the same infective material in its intestinal discharge, and that the epidemic only ceased because the susceptibility of man had passed away, then the bacillus would continue to exist in the tank, always supposing that there was sufficient pabulum for it. And thus it is most probable that the bacillus gets into the tank from man, and not *vice versâ*. Whilst Koch was in Calcutta the English physicians there imbued him with their views on cholera and drinking water. The English had been brought up on the drinking water theory of typhoid fever and cholera, and could only lay it aside with difficulty. But a few of those English physicians who had studied widespread epidemics had renounced their original ideas. Dr. Bryden (the chief of the Statistical Department), Dr. J. M. Cuningham (the sanitary commissioner), Dr. John Macpherson (the Inspector-General of the Bengal Army), Dr. Lewis, and Dr. Douglas Cunningham were all disbelievers in the drinking-water theory. Koch was further strengthened in his views, in opposition to the few Englishmen just named, from the fact that after Fort William in Calcutta was supplied with pure water no more cases of cholera occurred there, although it had formerly been ravaged by the disease. The gentlemen in Calcutta had not, however, told Koch the whole truth. For it was a fact that cholera had begun to decrease in Fort William since 1863, and yet the fresh water-supply was introduced as late as March 25th, 1873 Moreover, it was not true that the only improvement then effected was a change in the water-supply, for many other changes were carried out, the fortress being made a model of cleanliness. Alterations in the drainage of the soil were effected in and around the foundations of the building, which before this was nothing more than a morass during the rainy season; so that, inasmuch as the nature of the soil, as well as the drinking water, was changed, the case of Fort William affords an argument as much in favour of the localists as it does for the contagionists. I may here call to mind an episode which was much commented on at the time, and which is perhaps of the nature of an experiment. Macnamara writes, in his work on Cholera: "In connexion with this position I may narrate a case which happened in another part of the country, but for which the facts can be vouched. Some dejecta from a case of cholera found their way into a jug of drinking water, and the mixture was exposed to the heat of the sun for the day. Early the next morning a small quantity of this water was drunk by nineteen individuals. Nothing was noticed, either in the appearance or taste of the water, by those who had partaken of it. All remained well during the first day. On the following morning one man was seized with cholera as he awoke; the others remained well till the second day had passed, when two more cases of cholera occurred, and the day after that two other cases were observed. The rest of the party remained well till sunset of the third day, when again two were seized with illness. These were the last cases, and the other fourteen persons continued to enjoy immunity from diarrhœa, cholera, or any disturbance of health." This case is, etiologically, not worth much. Where was the original case from which the infection was supposed to have come? Was it not possible for the nineteen persons to be brought under the same circumstances as those under which the original case had become affected? Were the nineteen in a place which was as a rule free from cholera, and could they only be affected through the drinking water? Several cases in India are known to me where guests at a banquet having drunk no water were yet the victims of cholera. For instance, at a baptismal feast which a sergeant gave a gallon and a half (six litres and three-quarters) of rum was supplied. Twelve persons, including the man and his wife, sat down to the banquet, and on the following evening the whole of the group, except the baby which still lives in Calcutta, were in their graves. At this feast there was no question of a mixture of anything with the stools of cholera.

When I ask myself how it is that men usually astute can place such implicit reliance on the drinking-water theory, which entails such ambiguity and contradiction, I can only think of two reasons. Partly, no doubt, there exists the belief that on general hygienic grounds no stone should be left unturned in order to procure a good supply of water where it had previously been bad, and thus the fear of death and the devil proves stronger than the love of truth and God. Again, the drinking-water doctrine appears to many to be the lesser evil as compared with the threatening local and periodical predisposition, which implies a more mysterious and less definable conception. They imagine that the, to them, uncomfortable facts of time and place may be explained on the drinking-water doctrine. The places where the cholera excreta can contaminate the drinking water have a local disposition, and the times at which even cholera prevails, and excreta may contaminate springs and watercourses, have to do with periodical dispositions, and thus they escape from explaining the subtle influences of soil and ground water. But anyone who thoroughly investigates the local and periodical factors in epidemics of cholera must reject such an explanation. A study of the tables previously given from Brauser places great obstacles in the way of accepting these doctrines. The constant periodicity of cholera in Calcutta or Madras cannot thus be cleared up. In the same way it is impossible to understand on this doctrine how it is that the hot dry season, which must be destructive to the bacilli, is the period during which cholera is most prevalent, and how it is that in the hot and wet season, which is favourable to the growth of bacilli, cholera is at its lowest ebb. That cholera and typhoid fever are more flourishing when the ground water is sinking than when it is rising has been explained by the drinking-water theorists on the view that when the ground water is falling it becomes more concentrated, thicker, and therefore more dangerous. Now, the prolonged researches of Wegner, Aubry, and Port have proved the direct opposite. When the ground water is low it is always purer than when high. Dr. Port has studied for a number of years the state of the water in the garrisons of Munich with a view of watching its relations with the movement of typhoid fever, and he has found that when the water began to be impure then a falling off in the disease might be predicted. Why this should be so has received an experimental explanation from Dr. Franz Hoffmann. Great and numerous are the objections to the explanation of the local disposition to cholera by means of the drinking-water doctrine. Lyons was until the year 1858 supplied with water from superficial wells. The analyses of the waters from a number of the wells prior to the introduction of a better supply would astonish anyone. The contagionists get out of their difficulties by merely asserting that though it is always the water which transmits cholera, yet there are a thousand ways in which this may be accomplished. But we have already shown that severe epidemics may occur without

Digitized by Google

drinking water being implicated, and consequently it is questionable whether, in those epidemics where the water may have been a factor, other causes did not play a more important part in the development of the malady. It is for the contagionists to prove why the infection by drinking water can only be verified in certain cases. The most popular argument of the contagionists is the proposition that cholera spreads by human intercourse, a fact which I unhesitatingly accept. But the interpretation which the contagionists put upon the fact is nullified by the fact itself, as is shown by a closer study of all the influences of intercommunication, whether by land or sea.

In many regions there are main streets running in watered valleys in the direction of the stream, and yet other principal streets having a direction at right angles to that of the stream. In these streets, as is well known, at short intervals there exist sites which may be dotted on a special map where the frequency of cholera may be investigated, just as I had done for the epidemic of 1854 in Bavaria. It transpired that the sites of the epidemic preferred to spread in the length of those streets in the valleys which followed the course of the stream. When, however, one investigated the epidemic spots in streets which cross valleys between which hills or tablelands lie, it was found that the cholera attacks those sites which lie in a valley which crosses the streets, and the places which are situate on the heights between two valleys are spared. In the valleys, however, which are only crossed by one principal road, the epidemic spreads itself in places which lie in the valley upwards and downwards in the direction of the river, although the intercommunication may be very slight and the river not navigable. In Central India for a long time the great rivers were the principal means of communication, and the cholera spread by preference along these routes. When in recent times the Indian railways were started, it was thought that cholera would forsake the old routes and travel along the railway. But such was found by Cornish not to be the case. Of course the same statement holds good in Europe. Saxony is perhaps as thickly peopled and as much overrun with railways as any State in Germany. Since 1836 cholera prevailed in Saxony on no less than eleven different years; but, as Reinhard and Günther have proved, its propagation was not in any way directed by the developing network of railways. Certain places in Saxony always were the centres for cholera, and so remained despite the railways. Freiberg, in Saxony, was never visited by cholera either before or after the railway was completed, whilst certain parts of the Mulde and Pleisse Thal were regularly visited. As often as an epidemic of cholera broke out in North or South Germany, cases were observed in Saxony; but for an epidemic to develop in Saxony always required time. Every year in Saxony which was marked by a heavy death-rate from cholera was preceded by a year during which the mortality was comparatively slight. Thus, in 1849 there were 488 deaths; in 1850, 1551; in 1865, 358; and in 1866 as many as 6731; again, only 4 cases in 1872, but 365 in 1873.

If the cholera can be brought by sufferers direct from India to Toulon, where the sea-passage lasts only three weeks, then if the disease prevail in North Germany it must always spread to South and West Germany, and inversely, since we have nothing but cholera on the one hand and healthy people on the other. But whoever studies the history of cholera will find nothing but contradictions of this postulate of the contagionists. In 1854 Berlin took no cholera from Munich, and in 1866 Munich received no cholera from Berlin, notwithstanding extensive intercommunication during the Industrial Exhibition and despite the war.

(To be continued.)

THE HOSPITALS ASSOCIATION.—At the general meetings of this Association to be held during the winter, papers on the following subjects, amongst others, will be discussed: On Hospital Ships, by Dr. P. Murray Braidwood; Rediscussion of the Out-patients Question, by Dr. J. S. Bristowe; on Horse Ambulances in connexion with Hospitals, by Captain William Joynson, chairman of the Northern Hospital, Liverpool; Relation of the Provident Dispensary to the Hospital, by Mr. C. J. Radley. The opening meeting will be on Dec. 6th, but it will take the form of a *soirée*, and will be held at the rooms of the Medical Society of London, No. 11, Chandos-street, Cavendish-square, when the members will be received by the Council of the Association.

CHRONIC CATARRHAL LARYNGITIS:

ITS VARIETIES, WITH THEIR ETIOLOGY, PATHOLOGY, AND CLINICAL RELATIONS.

By GORDON HOLMES, M.D.,

PHYSICIAN TO THE MUNICIPAL THROAT AND EAR INFIRMARY, LONDON CONSULTING PHYSICIAN TO THE SHEFFIELD EAR AND THROAT HOSPITAL.

(Concluded from p. 868.)

III. GLANDULAR LARYNGITIS.

Semeiology.—Subjectively considered, the symptoms of this malady have a decided character as regards voice and local sensations, and are even distinct from those of the two affections already described with respect to cough and expectoration. (*a*) Under ordinary circumstances the patient does not suffer from hoarseness, except in cases of a rarely aggravated type; but in a majority of instances the complaint of not being able to emit high or acute vocal tones is made. This symptom, it will be seen, is an etiological one, as it is not likely to be noticed or dwelt on unless by professional speakers or singers. (*b*) A sensation in the throat of heat and pricking or stinging usually accompanies this disease, and in the more pronounced instances has a very troublesome and persistent character. In addition, dryness of the throat, provoking frequent efforts of swallowing, in order to gain the moistening influence of the saliva, is very constantly present. (*c*) Hacking efforts, so common in the two former kinds of catarrhal laryngitis, and involuntary cough, scarcely exist in this malady. (*d*) Expectoration also is conspicuous by its absence. The condition of the larynx, being one of abnormal dryness demanding extra deglutitory acts for the sake of moisture, does not favour the development of this and the last symptom. Small shreds of partly dried mucus are, however, sometimes raised by voluntary coughing. (*e*) As regards dysphagia, pain, spontaneous or on external pressure, and constitutional symptoms, they are rarely if ever present, and in uncomplicated cases can never attain to any marked degree.

The *objective* sign of this malady is a granular condition of the mucous membrane in those positions where the racemose glands or follicles[1] are most numerous. This phenomenon must, therefore, be especially looked for over and along the sides of the arytenoid cartilages, chiefly towards their front aspects. Such is the most constant site of the granulations, but they may occur to a lesser extent in other places, particularly on the cushion of the epiglottis. In slight cases the elevations are few, but in advanced examples they may be so numerous and closely packed that the affected surface has the appearance of a fine shagreen. In the early stages they present a red or congested colour, but after they have been in existence for many months this hue is gradually lost, and finally replaced by a dirty white or greyish tint, most evident at the centre of the summit of each granulation. The patches or filaments of white concretion or exudation, so constantly seen in granular pharynx, are seldom or never observed in this, the analogous condition of the larynx. In the most developed and persistent cases, however, the top of each elevation may become the seat of a minute ragged opening, to some extent to be considered as a small perforating ulcer. The ordinary state of the mucous membrane generally is one of slight congestion and dryness; but, in the milder cases it may be comparatively healthy outside the granulations, whilst in the worst type of the malady it has a markedly dry, dusky, and thickened appearance. In pathological, or at least etiological, association with follicular laryngitis elevations, seemingly of a dense and indolent hypertrophic character, are occasionally met with on the vocal bands, especially on their free edges. This is the con-

[1] Coyne's (*op. cit.*) discoveries are briefly:—(1) The bed adjacent to the epithelium consists of a reticulated lymphoid tissue, such as is found in similar relationship in the small intestine. (2) Closed follicles, similar to those of the small intestine, exist in the superficial part of the mucous derma, estimated at thirty to forty in number. (3) On the free edge of the vocal bands papillæ are found, "certainly vascular and probably nervous": they are best developed anteriorly. Kölliker, Rauchfuss, &c., had denied the existence of follicles in the larynx. In 1863 Rüdinger (loc. cit.) had said: "The laryngeal mucous membrane, as is unanimously proved, possesses nowhere a trace of a papillary body." In 1873, however, Luschka (Der Kehlkopf, &c., p. 140) asserted the existence of papillæ, though few in number, in some parts of the larynx. These, according to Coyne, were merely folds of the mucous membrane.

Digitized by Google

dition named "chorditis tuberosa" by Türck.[2] It is rare to find more than a single tuber or node in any given instance. A more extended disease of the kind is spoken of by Türck as trachoma of the vocal bands, in which a more general thickening or mammillated condition of the ligaments is observed.

Pathogenesis.—The leading cause of this disease is excessive use of the voice in public speaking or singing, but those who suffer probably always have a constitutional predisposition in the form of some cachexia, either strumous or the so-called "herpetic diathesis" of the French pathologists.[3] But the direct subsidiary cause is persistent overwork of the racemose glands and follicles of the laryngeal mucous membrane, and the affection has a perfect etiological analogy with the skin disease named lichen tropicus, or "prickly heat," in which a continued and exaggerated demand on the cutaneous sweat glands urges them into a state of subacute hyperæmia and inflammation.

The most detailed and reasoned description of follicular laryngitis has been given by Krishaber and Peter;[4] their conception of the process by which the malady is brought about in professional voice users is well worthy of reproduction in their own words: "In these cases the mucous membrane is brought every instant in contact with air rapidly inspired, which has not passed through the nose and its channels, so as to be there warmed and moistened, and which consequently arrives in abundant quantity, cold and dry, in the pharynx and larynx. To combat the aridity which parches it, the mucous membrane secretes sufficiently for the lubricating of its surface. With this object all the pharyngo-nasal and laryngeal glands combine their action. Now all repeatedly exaggerated secretion is a cause for hypertrophy of the organ at work; hence then is hypertrophy of the pharyngeal and laryngeal glands. As to the pharyngeal glands, however, we have only a physiological act in response to a necessity; they secrete merely because solicited by the cold air. But we shall see that the glands of the larynx not only obey this same solicitation, but that a wholly mechanical cause intervenes to exaggerate their secretion. This mechanical cause is none other than the proper and multiple movements of the larynx, in which the mucous membrane is found to be compressed, elongated, thrown into vibration—in a word, influenced by the essential mechanism of function." Hence as the parts of the larynx most rich in glands—viz., the arytenoid cartilages and the interarytenoid fold,—are also the principal seat of the intrinsic motions of the organ, the site of glandular laryngitis agrees practically with the coincidence of the anatomical and functional causes. These observations apply in a lesser degree to the base of the epiglottis, which is the second seat of motion. The difficulty of producing high notes is also well explained by Krishaber and Peter. It clearly depends on the thickening of the tissues over and between the arytenoid cartilages, which being thus hampered in their action cannot close the glottis tightly, especially at the intercartilaginous portion. Hence the fixity and tension of the vocal bands necessary in the upper register of the voice are insufficiently attainable. This symptom would of course arise in any form of laryngeal disease accompanied by thickening in the same position, and is only particularly associated with glandular laryngitis on account of the frequency of this affection amongst the members of voice using professions. Apart from excessive vocal exercise, glandular laryngitis arises sometimes from the more ordinary sources of throat irritation—i.e., abuse of alcohol, inhalation of acrid vapours or powders, smoking in excess, &c. Under the circumstances, however, it is rarely primary in the larynx, but is an extension of a previous pharyngeal attack. With respect to age and sex, the disease is almost peculiar to the early years of adult life, and is considerably more common in the male sex. Statistics have not yet been collected to ascertain definitely these points. In twenty-one well-recognised cases of my own all occurred between eighteen and thirty-three; seven were females. In nine instances, however, the chief seat of disease was the pharynx.

Pathological anatomy.—Autopsies and other investigations by Lewin,[5] Rüdin,[6] Türck,[7] Rindfleisch,[8] De Mussy,[9] and Rheiner[10] are in evidence to determine this part of the subject. The first step of the morbid process appears to be a dilatation with catarrhal proliferation of epithelium of the orifices of the racemose glands. Gradually the whole interior of the glands becomes similarly involved, they pass into a state of persistent hyperæmia, whence a weak but long-continued hyperplasia, and eventually a permanent hypertrophy of their whole substance. The manifest swelling of the glands, however, which gives rise to the granular condition of the mucous membrane is chiefly the result of distension of the cavities by undischarged secretion. This complication is the immediate result of the diseased action at their aperture and in their ducts. At first these become blocked, and afterwards their walls partially agglutinate through imperfect plastic efforts at repair. Later on the pent-up secretion forces its way outwards, and compels the reopening of the ducts, which henceforth are in an irregular and eroded condition, especially at their external apertures. Hence originates the appearance of minute but deep ulcers, few of which have the superficial area of an ordinary pin's head. Such parts of the mucous membrane as do not contain diseased glands are generally free from morbid changes except in contiguity with the granulations, where as a rule a state of simple chronic catarrh prevails. In typical and long-standing cases there may be a general hypertrophy of epithelium, and it occasionally happens that the chronic hyperplasia fixes itself on the dermoid layer of the mucous membrane, which becomes hypertrophied and exhibits papillæ like those of the skin; a class of bodies which are very rare, and until Coyne's researches were thought to be entirely absent from the normal larynx. This latter condition is that first described and named by Förster[11] "dermoid metamorphosis." Such, doubtless, is the nature of the lesion which, when affecting the vocal bands in an irregular manner, gives to the nodular thickening before mentioned as trachoma or chorditis tuberosa.

Diagnosis.—The history of the case, and the etiological inferences therefrom, will often lead us to surmise the existence of glandular laryngitis; and when the pharynx is in a granular state, with subjective symptoms emanating from the larynx, there will be little room for doubt as to the precise pathological condition of the latter organ. But the elevation caused by the diseased glands must be seen with the laryngoscope before a final decision can be arrived at. A better illumination of the larynx is required for these cases than usually suffices for the recognition of other lesions of this part. In the earlier stages of the malady scattered red points will be seen, and later on elevations, mostly in well-defined groups, in the sites of predilection already described.

Prognosis.—As the lesions in this disease extend too deeply to be easily influenced by the ordinary surface applications, the treatment is often protracted; but when the affection clearly springs from excessive vocal exercise, it will get well spontaneously on removal of the cause as readily as lichen tropicus disappears on changing to a temperate climate. Careful local treatment, with preventive measures, will nearly always effect a permanent cure.

Treatment.—As there is generally a constitutional taint, strumous or otherwise, appropriate remedies for its removal, such as cod-liver oil, iron, and other suitable tonics, will have to be administered. Occasionally there is no evidence of any but local disease, and in such instances it will be unadvisable to subject the patient to any general treatment. When the malady occurs in professional speakers and singers the practitioner should impress on the patient the importance of replenishing the breath as much as possible through the nose. The best teachers of elocution have generally counselled a strict adherence to nasal inspiration in public speaking, and considered that this simple measure has a most potent influence in guarding the health of the vocal organs. We even find that in the last century the knowledge of this hygienic fact, then only recognised by experts, was believed to be of such value that it was [illegible] sold for a large sum under a pledge of secrecy.[12] In singing, however, the necessity of keeping exact time often precludes rapid inspiration through the mouth; but [illegible] there are natural pauses in every melody, which [illegible] advantage of to refill the lungs through the nose.

As regards *local* treatment, warm [illegible] of steam medicated with benzoin, [illegible]

be most useful as palliatives when there is much heat and irritative sensation. Astringent lozenges of kino, rhatany, tannic acid, &c., will often much lessen hyperæmia, and daily applications of solutions of perchloride of iron (two drachms to the ounce), sulphate of copper (twenty grains to the ounce), or chloride of zinc (thirty grains to the ounce), simultaneously, may banish this symptom entirely from the surface. Such measures will sometimes suffice to effect a cure in mild and incipient cases. In more obstinate instances insufflation of astringent powders (alum, gallic acid, borax, powdered catechu, &c.), two grains at a time, through a curved tube brought close to the larynx, will be found effective. At the same time the patient may use the astringent solutions of half or quarter strength in the form of spray inhalation, two or three times a day for five minutes at a time. In the long-standing and fully developed examples, however, when the granulations are present in considerable number, an application of more causticity is absolutely necessary, so as to destroy gradually the substance of each elevation. For this purpose nitrate of silver is the only safe and convenient salt. It must be used in the solid form, the end of a curved sound or probe being coated with it (as originated by Lewin), daily, or on alternate days; the caustic must be pressed closely to each granulation or group of the same, by the aid of the laryngeal mirror; and the process must be continued until the elevations are brought down to the level of the normal mucous membrane.

Finsbury-square, E.C.

INTESTINAL RESECTION.

BY C. EGERTON JENNINGS, M.S., F.R.C.S ENG.,
ASSISTANT-SURGEON TO THE NORTH-WEST LONDON HOSPITAL.

THE following experiments were performed, at the suggestion of Sir Spencer Wells, to test the value of a method for removing portions of intestine. Afterwards, the edges of the intestine, above and below the part removed, would be adapted, a cylinder having been previously introduced within the gut to facilitate the application of the sutures. Cylinders, hollowed into tubes with stout walls, conical at either end, have been cast for me in cocoa butter in eight different sizes, the smallest cylinder being of a size suitable for the small intestine of a child, the largest appropriate for the colon of an adult. After the operation the cylinder would be melted by the heat of the body, and the fluid would pass harmlessly along the interior of the intestine. Sir Spencer Wells suggested that perhaps gelatine would be the best substance for the composition of the hollow or tubular cylinders. So prepared they are slightly flexible, a very important advantage where it is impossible to withdraw much of the intestine from the abdomen during the operation. The cylinders are made by Probyn and Company.

Experiment 1.—Performed on a black-and-tan bitch, weighing 16·3 lb. July 18th, 4.20 P.M.: Subcutaneous injection of a grain and a half of morphine and one-fifty-sixth of a grain of atropine. 5.30: Ether, mixed with a little ammonia, was administered, that the fluidity of the blood might be well maintained during the operation, and every bleeding point secured. Listerian precautions, save the spray, were taken. After the abdomen had been opened in the linea alba to the extent of 3½ in., a piece of the small intestine was withdrawn, but at once returned into the abdomen, since the smallest cylinders which had been provided were of considerably larger size than the ileum of this animal. The sigmoid flexure was therefore withdrawn and isolated from the abdominal cavity by being passed through a small aperture made in the centre of a sheet of carbolised gutta-percha tissue. A piece of the gut about 2 in. in length was separated, from the remainder of the knuckle, by two ligatures. A triangular portion of the mesentery was excised, the base of the triangle corresponding with the part of the bowel included between the ligatures. All bleeding points having been secured—the hæmorrhage was very great,—the intestine was cut through with scissors above the upper and below the lower ligature. A cocoa-butter cylinder having been inserted, the edges of the bowel were united at a point diametrically opposite to the mesenteric border by an interrupted Lembert's suture of fine carbolised silk. By means of two continuous sutures, which included the peritoneal and muscular tunics, the remainder of the circumference was closed. The divided edges of the mesentery were coapted by chromicised gut ligatures. The intestine (with the cylinder within it) was returned into the abdominal cavity, and the wound in the linea alba was united with interrupted silk sutures. After the experiment the animal was rather collapsed. 19th, 10 A.M.: This morning the dog awoke apparently quite well, and even ran about. The cocoa butter had evidently dissolved during the night, for some of it had escaped per anum. The wound looked healthy and smelt sweet. Redressed; no signs of peritonitis. Hypodermic injection of a grain of morphia and $\frac{1}{128}$ of a grain of atropia. The dog passed a small dark stool immediately after this injection. Slept well till 8 P.M. Given milk only to drink. 20th, 10 A.M.: Unfortunately during the night another dog, tied up in the same room, slipped its collar, and bit through the cord which secured the subject of the experiment. The dressings were found removed, and both the dogs had been running about the room. Now the animal lay on its side; the abdomen was tympanitic, and very painful to the touch. Respiration 60 per minute. A subcutaneous injection of a grain of morphia and one-eighty-fourth of a grain of atropia was at once given to relieve pain and promote the euthanasia. Death occurred at 11.45 A.M. Dr. D. van Duyse kindly made an autopsy forty-eight hours after death. There was general peritonitis. The intestinal sutures had given way, so that the interior of the intestine communicated with the peritoneal cavity by an aperture about equivalent to a third of the circumference of the gut; therefore the fæces escaped freely. It seemed quite probable that the ends of the gut, which had been united by the sutures, were torn apart, during the night previous to death, by the movements of the dog. On inspecting the interior of the gut, one point of the suture had pierced the mucous membrane and had ulcerated through it.

Experiment 2.—Performed on a bitch weighing 16 3 lb. July 21st, 3 P.M.: Subcutaneous injection of one grain and a half of morphia and one-fifty-sixth of a grain of atropine. 4 P.M.: Injection repeated and chloroform administered. An incision 3½ in. in length was made obliquely through the abdominal wall, parallel and internal to the position of the sigmoid flexure. Two inches of the intestine (the upper part of the rectum and the lower part of the sigmoid flexure), were removed. A triangular piece of the mesentery was first excised, and the cut edges were adapted with a chromicised catgut suture. The intestine was divided a little obliquely in order that after union the line of junction should be of rather greater length than the normal circumference of the gut. A little fæcal matter escaped into the peritoneal cavity during the insertion of the cylinder into the ends of the intestine, but it was sponged away carefully. Continuous and interrupted silk sutures, exceedingly numerous, were used, to maintain the peritoneal surfaces in accurate contact. The greater part of the abdominal wound was closed with a continuous catgut suture, the remainder, the lower part, was closed with interrupted sutures. The animal being collapsed after the operation half a drachm of brandy with water was injected subcutaneously. 22nd, 9 A.M.: The bitch looked very well; dressings displaced; fæces had passed naturally during the night; the tail, anus, and pudenda were covered with fæces and cocoa butter; incontinence of urine. The parts were thoroughly cleansed immediately and the dressings were reapplied. The wound appeared aseptic. Subcutaneous injection of half a grain of morphine with $\frac{1}{128}$th of a grain of atropine. The animal was found dead at 12 30 P.M. An autopsy demonstrated recent peritonitis of a local character. The intestinal sutures were all properly in place, but on forcing water with a syringe through the piece of gut, after its removal, there was a slight leakage noticed at the seat of resection. The sutures were numerous and very closely set, but apparently not close enough just at the point of attachment of the mesentery. This seems to be the part to which attention should be specially directed during the operation.

Experiment 3.—A black dog, weight 47·35 lb. July 22nd, 3 P.M.: The operation was performed under chloroform, four grains of morphia having been previously injected. A piece of the small intestine was withdrawn from the abdomen, through an incision three inches in length, made in the linea alba. A triangular piece of the mesentery was excised, and the edges adapted with a continuous chromicised suture, as in the last experiment. A cylinder of rather larger size than the calibre of the gut was selected, so that after the removal of about two inches of the intestine, the ends of the

Digitized by Google

gut were distended by the insertion of the cylinder. The ends of the gut were united by two rows of fine silk sutures, an inner row joining the edges of the peritoneum and muscularis, and an outer row of Lembert's sutures. These stitches were exceedingly closely set, and after the cylinder had melted they would lie still closer together, for the intestine would then contract to its normal calibre. The operation was concluded in the ordinary manner. 23rd, 10 A.M.: The dog looked quite well. It drank milk-and-water. It had tossed about a good deal during the night, and had displaced the dressings. Wound redressed; it appeared aseptic. Two grains of morphia injected subcutaneously. Vomiting immediately followed the injection. Somnolence. 12.30 P.M.: The dog was not asleep. It looked quite comfortable, lying on the abdomen, with the head resting between the fore-paws. Subcutaneous injection of a grain of morphia and one-sixty-fourth of a grain of atropine. No vomiting. Asleep. The dog died during the night. 24th: The autopsy was made by Dr. van Imschoot. The abdominal wound had closed. There was peritonitis, radiating from the seat of resection as a centre. A piece of omentum had adhered to the abdominal wall and had compressed the gut just below the resection. Great tension was thus put on the line of suture, which gave way, to a small extent, at the convexity. The remainder of the intestinal wound had united satisfactorily.

Remarks.—The employment of hollow or tubular cylinders undoubtedly facilitates the performance of intestinal resection, and therefore considerably shortens the operation. It appears a great advantage to make the section of the abdominal wall directly over the part of the intestine to be removed. The application of the sutures is clearly the most important point for consideration. Braided silk is to be preferred, for it will not kink. Continuous sutures can be applied more speedily than interrupted ones, but if one point of the continuous suture gives way, the entire suture loosens. Doubtless the last dog perished from a complication which could hardly be anticipated. And I believe the other dogs would have survived had they been kept in a state of perfect quiescence after the operations; a thing very difficult to accomplish with dogs, but very easy with mankind. Sir Spencer Wells advises that the legs of the dogs should be tied together after the experiments. This plan would certainly be more effectual than the use of morphia, unless the injections are very frequently repeated, for the action of this medicament on dogs is but transient. To Prof. Boddaert van Custem, of Ghent, I am exceedingly indebted for the kind assistance he rendered me in conducting these experiments.

ON THE

"DISCOVERY OF ONE OF THE 'SEITES' SET APART (IN WHITECHAPEL) FOR A PEST-GROUND IN 1349, *TEMP.* EDWARD III."

By ROBT. FOWLER, M.D., M.R.C.P.E.,
PRESIDENT OF THE HUNTERIAN SOCIETY.

In July last I was instructed by the Metropolitan Board of Works to examine a site of ground in Cartwright-street, Whitechapel, and to report as to whether there were any sanitary conditions preventing the utilisation of the ground for building purposes, and generally as to the condition of the human remains lying therein. The locality of the site is well indicated in the subjoined plan (Lot 3). This site in 1875 formed a portion of an area of about six acres or thereabouts, which comprised some courts and alleys of the most wretched description, inhabited by a population of some 3750 persons. The entire area, according to the then medical officer of health of the district, afforded upon an average 8·2 square yards, but in some of the courts only 3·4 square yards, to each person, the average number of persons to a house in the entire area being 8·3.

On July 27th, 1875, the medical officer of health made an official representation of the unhealthiness of this area to the Metropolitan Board of Works, and used this strong language in his report:—"I desire to represent to your board that by reason of the closeness, narrowness, and bad arrangement, as well as by reason of the bad condition, of the courts and houses within such area, diseases indicating a generally low condition of health amongst the population have been from time to time prevalent; and the death-rate of such population has been excessive, such excess being more than 50 per cent. above the ordinary rate of the district of Whitechapel, of which it forms a part. I further desire to represent that the evils connected with such houses, courts, and alleys, and the sanitary defects in such area, cannot be effectually remedied otherwise than by an improvement scheme for the rearrangement and reconstruction of the streets and houses within such area, or some of such streets and houses." The ground was cleared in 1881; and in consequence of the recent discovery of "human remains lying therein," I was consulted accordingly. Three trenches, about 6 ft. square each, and of varying depths, were dug for my inspection. These trenches are marked respectively A, B, and C on the accompanying plan. A was exceedingly shallow, and, so far as I could observe, contained no human remains whatever. B was about 9 ft. deep, and was literally teeming on all sides with human bones. The skeletons were packed closely,

one upon the other, from within 2 ft. of the surface to the very bottom of the trench. C was about 4 ft. deep, and also contained many human bones. Here and there were distinctly visible the remains of decayed (possibly coffin) wood around and between the skeletons. In this trench, about 2 ft. from the surface (having apparently dry ground intervening), was a patch of about half a yard square of somewhat humid, sodden, greasy earth. It is very possible this was simply the result of rain percolation; at all events, in no other part of the excavated ground were similar appearances to be found. I was thus firmly convinced that the spot had been an old burial-ground, and being desirous to establish—first, its extent, I had two trenches dug respectively 50 and 100 ft. to the north of the former trenches. In neither of these two northernmost trenches (respectively marked D and E on the plan), although each was of the depth of at least 11 ft., in fact down to the sand or gravel, were there found any human bones whatever. The excavated earth contained simply some few bones and horns of certain of the lower animals. It would therefore appear that the human remains were confined to so much only of the site of ground I had to examine as was comprised within about 120 ft. by 60 ft. of

[1] Read before the Hunterian Society on Wednesday, Oct. 8th, 1884.

Digitized by Google

its southernmost boundary. That this was but a portion of an old burial-ground, which extended further southwards under the present Darby-street, and certain cottages and schools on the south side of this street, is conclusively shown by a reference to Roque's map of Ancient London, dated 1746, wherein the whole plot delineated on my plan is called "Aldgate churchyard," and what is now Cartwright-street is named "Churchyard-alley." In the next place, it was very important for me to determine, if possible, the age of this burial-ground; or, in other words, the latest period when interments were made therein.

I deduced this from the following data:—(*a*) Omitting the slight exceptional condition existent in Trench C, the whole of the human remains I examined were in a dry, and, so far as exhalations are concerned, comparatively inert condition. They were simply old and dried bones. Dr. Navier, of Chalons, in 1775,[2] states that after twenty years' burial a body has been found "covered with flesh, and in a state of putrefaction." (*b*) Walker's work on graveyards was published in 1839. It was the work which led to the abolition of intramural burials, and to the establishment of the present cemeteries. This ground in Cartwright-street is in no way alluded to by Walker, although he speaks of Aldgate Churchyard in the High street as "truly alarming,"[3] and of the burial-ground of St. Mary's, Whitechapel, as "extremely disgusting."[4] (*c*) No burial-ground has existed in Cartwright-street within living memory. The former owner built, in 1852, the houses upon this very ground, which was then called the "Ruins." He distinctly remembers human bones being turned up whilst the foundations were being put in. These foundations were laid at a depth of about 4 ft. from the true surface of the ground, and after 4 ft. of super-accumulated soil had been previously removed. As a matter of fact, in Trench B the foundations rest in some places immediately upon human skeletons, and in other places human bones are interspersed amongst the brickwork. The memory of this gentleman goes back to 1832, when the Asiatic cholera was exceedingly fatal amongst the inhabitants of the old houses built upon the adjoining land. He tells me that a nonagenarian friend of his died a few years ago, and that in repeated conversations this old man said he never remembered the place as a burial-ground, but had been told that an old "brewery" once stood there. (*d*) The former owner of these houses assures me that he never remembers any subsidence whatever of the walls of the houses during the thirty years of their existence. This assertion is fully confirmed by the present stable appearance of the schools on the south of Darby-street, and of the adjoining cottages which were part of the said owner's block. (*e*) In the second edition of Richard Horwood's Map of London, 1809, the whole adjoining land appears covered with houses, and the courts and alleys have the same names as when they were cleared in 1881 by the Metropolitan Board of Works. Cartwright-street appears on this map; but the burial-ground shown on Roque's map of 1746 is not named in Horwood's map; a blank space, however, not covered with houses, corresponds with the actual site. This was doubtless, even at that time, the "Ruins." No burial-ground existed in Cartwright-street at the commencement of this century. (*f*) John Noorthouck, in 1773,[5] wrote these words:—"At the south end of the Minories the street opens upon East Smithfield and Tower Hill; and between both these plots of ground once stood a religious foundation called by the several names of the New Abbey, the Abbey of Grace, and East Minster. This house was founded by King Edward III. upon the seite of the pest-ground, ... and called the Churchyard of the Holy Trinity; and upon the seite of that abbey is built the King's Victualling Office, which stands on the upper part of Little Tower Hill, near the end of King-street. This building contains ..... (*inter alia*) a brewhouse." This quotation fully corroborates the statement of the nonagenarian friend of the former owner that an old "brewery" once stood there. This fact of the concession of the religious house is also alluded to in similar language by Stow.[6] He says:—"This house (the monastery) at the late general suppression was valued at £546 10*d.* yearly. It was surrendered in the year 1539, the 30th of Henry VIII., since the which time, the said monastery being cleane pulled down by Sir Arthur Darcy Knight and other; of late time (in place thereof) is builded a large store house for victual, and convenient ovens are builded there for baking of bisket to serve his Majesties shippes. The grounds adjoining and belonging to the said abby are imployed in building of small tenements." Furthermore:—(*g*) In the map by Ralph Aggas (1562) of "Ancient London in the early part of Queen Elizabeth," the Eastminster is shown to have been then located on this very spot, now covered by the Royal Mint,[7] with the ground behind and to the east of it. The Royal Mint, as it is to-day, was completed in 1811. Ground adjoining thereto is still called "Victualling Office-square." I am thus led irresistibly to the conclusion that the plot of ground I was instructed to examine in Cartwright-street was no other than one of the "seites" set apart for a pest-ground in 1349. Under this date, *temp.* Edward III., Noorthouck[8] says:—"A great plague which first appeared in the northern parts of Asia now spread over Europe, ... At length it reached London, where the common cemeteries were not capacious enough to receive the vast number of bodies; so that several well-disposed persons were induced to purchase ground to supply that defect.....There was also another piece of ground purchased at the east end of the city, just without the wall, by one John Corey, a clergyman, for the same use; on which spot was afterwards in this reign [in 1359][9] founded the Abbey of St. Mary of Grace, for Cistertian monks; it is now covered by the Victualling-office and adjoining houses. It was asserted that not one in ten escaped this calamity, and that not less than 100,000 persons died in the whole." Other old writers[10] allude more or less in detail to the above facts. This horrible pestilence was no other than the so-called "black death," or "great mortality," which, probably originating in China, entered the western countries of Asia, and was brought to Constantinople from the northern coast of the Black Sea. It devastated Europe from 1347 to 1351. Hecker[11] assumes that Europe lost during the "black death" 25,000,000 inhabitants, a fourth part of the then estimated population of this continent. We know from Noorthouck,[12] and also from other authorities,[13] that the great plague in 1665, after devastating the western parts of London, became very violent in Stepney and Whitechapel. It is therefore just possible that the "seite," which had previously been used as a "pest-ground" when the plague visited London in 1349, and which site had also since then formed part of one of the religious houses, would be again utilised for the disposal of some of the dead amongst the plague-smitten of Whitechapel in 1665, and that during this year occurred the last interments of human bodies in this said ground. The mode of burial of the bodies indicates that the last interments were hurried, and not always conducted in a strictly orthodox way. Some of the skeletons, especially in Trench B, lie with the feet to the east, and others immediately below them with the feet to the west; and this is observed where the skeletons are apparently undisturbed far beneath the remaining foundations of the houses.

The result of the recommendations I made to the Metropolitan Board of Works is that the Board have decided not to build on the site of the graveyard. The "Disused Burial Grounds Act" passed this year will thus be complied with. The advice I gave the Board was not in the least influenced by any idea that these subjacent old dry bones had anything whatever to do with the necessity for clearing the ground. That the "low condition of health," and the "excessive mortality" of the inhabitants of this condemned area were due exclusively to the visible insanitary state of certain of the "houses, courts, and alleys," is pretty well proved by one great fact—viz., that all the houses built over and upon the burial-ground itself, with its substratum of decaying human remains, were of so healthy a character that in the first instance they were, for this reason alone, actually excluded from the improvement scheme; and the aid of the Home Secretary had to be invoked by the owner, on the plea of

deterioration of property, to compel the Board also to purchase this spot, or oasis of health, in the midst of its wretched insanitary surroundings.

Old Burlington-street, W.

FRACTURE OF THE BASE, FOLLOWED BY ENCEPHALITIS, ATAXIA, AND APHASIA; RECOVERY.

BY M. J. MOLONY, L.R.C.P., L.R.C.S. ED.,
ASSISTANT SURGEON, TREDEGAR IRONWORKS.

ON the night of April 11th, 1883, I was called to see W. W——, aged thirty-four, who had been found lying insensible in the street. He was ordinarily a strong healthy man. The following was the condition of affairs: Profound insensibility, pallor and coldness, copious hæmorrhage from left ear, slight epistaxis, pupils inactive and unequal, pulse intermittent, respiration slow and feeble. I noticed that there had been recent hæmatemesis. The blood vomited was of the dark peculiar colour which Sir Prescott Hewett describes when he speaks of fracture of the base, and which he attributes to the action of the gastric juice. Behind the left ear was an extensive contusion, best marked over the mastoid region, but also including the occipital and posterior cervical areas. There was no history as to how the injury had been received, nor has any clue been since discovered. The patient was of a rather bibulous and pugnacious disposition at times. The extent of the hæmorrhage from the ear, and the subsequent draining away of cerebro-spinal fluid, indicated beyond doubt a fracture of the base. How was the fracture caused? There was nothing whatever which pointed to either a fall or blow on the vault of the skull. The most careful examination revealed nothing. However, as we know that fracture by *contre-coup* may be produced without an external mark, the mere absence of injury at the vertex would of itself be of but little value. There was, however, the positive evidence of direct violence, applied if not actually at the base, at least in close proximity to it. I refer to the contusion at the mastoid and occipital regions.

No doubt Sir Prescott Hewett, in his article on Injuries of the Skull, lays some stress on the fact that discolouration may occur from the oozing of blood through the fracture, and the consequent infiltration of the cervical cellular tissue. But in this case the discolouration was most marked exactly in the region corresponding to the mastoid portion of the temporal bone, and presented all the appearance of a contusion in so pronounced a form as hardly to admit of a doubt as to its origin by direct violence. Moreover, the short period which had elapsed between the discovery of the man and my arrival—a quarter of an hour—would scarcely account for so extensive an infiltration. That the patient was found almost immediately after the injury there can be little doubt, as there were still many people in the streets. Thus I believe we have evidence of fracture of the base, caused in a manner by no means usual, or at least not commonly described. The treatment at this stage consisted in measures calculated to restore the heat of the body and to avert collapse. The application of warmth to the feet and sinapisms to the calves produced the desired effect. During the three or four days succeeding the injury the symptoms were such as one might expect to follow severe concussion, with probable contusion and laceration of brain substance. The pupils were still inactive and unequal; the pulse grew perceptibly stronger; the patient was semi-conscious and restless. He complained of headache and intolerance of light, and was, particularly towards evening, violent and delirious. Soon, however, he began to improve to the extent of recognising his attendants, and partially realising his position. The treatment now consisted in the application of cold to the head, purgation, and the administration of bromide of potassium. Morphia was also found useful in controlling the violent delirium. The case was now progressing favourably. The patient's faculties were gradually approaching the normal; the condition of the pupils was decidedly better; the delirium was less frequent and much less violent. About this time a remarkable symptom manifested itself, and pointed, I believe, to cerebellar mischief. This was a tendency to roll over repeatedly, and further, to roll continuously from side to side. This exercise was indulged in to an almost incredible extent, and was most distressing to the observer. Against any attempt to control the motion the patient protested most violently. Such symptoms are described by physiologists as occurring in animals whose crura cerebelli have been divided; and cases in which similar movements occurred in man have been recorded by MM. Seres and Belhomme, and by Dr. Paget. This phenomenon gradually disappeared, and on April 20th the patient, despite all efforts to prevent him, rose from his bed, dressed, and was with difficulty dissuaded from going out. Though less violent than hitherto, his condition seemed by no means favourable. His mind wandered; he was at times perfectly oblivious; his speech was jerky and incoherent; and his gait was distinctly ataxic. Between the 20th and 25th there was little or no alteration. On the 26th, and a few days afterwards, a distinctly new train of symptoms revealed themselves, and indicated beyond doubt inflammation of the brain: intolerable headache, rigors, quick pulse, pyrexia, intense photophobia; and subsequently strabismus, violent delirium, and convulsions. I applied ice to the head, purged freely, and gave aconite. Chloral and bromide were also useful. In the course of a few days the fever had subsided, the headache and other symptoms had considerably abated, and the condition of affairs was entirely satisfactory. Recovery now progressed steadily; and on May 5th the patient was allowed to sit up, but without leaving his room. He was now very good-humoured and tractable, and laughed heartily on hearing the tale of his previous performances. His condition at this period and for some time after, looked at from a physiological point of view, was of the most interesting character. The following symptoms were more or less constant: Headache, deafness, tinnitus aurium, strabismus, double vision, ataxia, jerky articulation, loss of memory, and aphasia. The strabismus, which was external and accompanied by other signs of paralysis of the third nerve, including ptosis and dilated pupil, disappeared in the course of a few weeks. The ataxia was well marked. The patient was unable to stand erect with his eyes closed. The movements of both upper and lower extremities were clumsy; the "muscular sense" was impaired. Westphal's symptom was also present, the "patellar reflex" being much diminished. The above motor derangement depended presumably on some cerebellar trouble, the earlier effects of which had already manifested themselves in the manner previously described. Loss of memory was a striking feature. While the patient's recollection of remote events was good, he utterly failed to remember recent ones. He called to mind without effort incidents of the Franco-Prussian War, yet he was unable to tell where he had been or what he had been doing three weeks before his illness. His memory for names of places seemed a complete blank. However, as he suffered from aphasia, it was of course a matter of great difficulty to decide when his failure arose from loss of memory pure and simple, and when it arose from aphasia, amnesic or otherwise. The aphasia was of a pronounced and complicated nature. I believe I was able to distinguish the amnesic, agraphic, and ataxic varieties, although to draw a hard-and-fast line where one variety began and another ended I soon discovered to be a hopeless task. Thus, for instance, on being asked his name he was unable to pronounce or write it. On hearing it he recognised it at once, and repeated, but failed to write, it. Then, again, on other matters he expressed himself correctly on paper where words of mouth absolutely failed him. On being asked his age he could not tell, but on being handed a pencil and paper he readily expressed it in figures. When he spoke for a little time his inability to coördinate the complex movements of articulation (ataxic aphasia) made itself apparent. During this latter stage a mild mercurial course, blistering, and iodide of potassium seemed beneficial.

As time wore on the above symptoms steadily disappeared, and in six months from the time I first saw him my patient was enjoying excellent health, in full possession of all his faculties and quite capable of attending to business. Deafness of the ear, from which the cerebro-spinal discharge occurred, was persistent.

The case, I believe, presents the following points of interest:—The somewhat unusual manner in which the fracture must have been produced; the distinct evidence of cerebellar mischief, the encephalitis supervening, as I ought to have mentioned, synchronously with the suppression of the cerebro-spinal discharge, the ataxic phenomena obviously depending on injury to the cerebellum; and, lastly, the loss of memory and aphasia.

THE EFFECT OF COCAINE UPON THE EYE.

BY LUCIEN HOWE, M.R.C.S.,
PROFESSOR OF OPHTHALMOLOGY IN THE UNIVERSITY OF BUFFALO, NEW YORK.

THE readers of English medical journals[1] may remember that about ten years ago attention was called to the leaves of the erythroxylon coca, and considerable interest manifested in their real or supposed effects. Of late notice has again been attracted to the plant by a brief communication made by Dr. Carl Koller of Vienna at the last meeting of the Heidelberg Ophthalmological Congress. From the number of those who are at work in the same direction it is probable that the literature of the subject will grow rapidly, and it therefore seems to me worth while to record briefly some of the conclusions arrived at, especially those based on experiments with animals. The practical bearing of the matter will be apparent when it is stated, without any fear of exaggeration, that the proper use of cocaine, before operations involving the conjunctiva, cornea, or iris, lessens the pain of the patient, and thus facilitates the manipulations of the operator, without producing any irritation or serious inconvenience. These deductions are drawn from the experiments mentioned, and upon an observation of the effect of cocaine in thirty-eight cases in the clinics of Professors Schoeler and Schweigger. To these gentlemen acknowledgments are due for the clinical material placed at my disposal. In a study of the subject we are led to consider the degree of anæsthesia produced. It is by no means easy to estimate this from the varying statements of patients. In order to obtain some measure, therefore, at least approximately, of the amount of pain in one eye as compared with another, it seemed possible to make use of the physiological fact that every irritant to a sensitive nerve is accompanied by a corresponding increase of blood pressure. Accordingly, by means of a mercurial kymograph, in the laboratory of Professor Zuntz, I have noted the effect upon the blood pressure when the same irritant was applied successively to each eye, and have made 124 such observations in various ways upon several rabbits. There were 104 of these tests, or 52 in pairs, which could be fairly compared; and, in addition, I have used occasionally guinea-pigs and cats when a verification of the experiment was deemed essential. The conclusions thus far may be briefly stated as follows:—

I. The effect of the same irritant upon the blood pressure, other circumstances being the same, is invariably less in the eye with cocaine than in the normal eye.

II. The degree of difference varies (1) with the amount of the dose, (2) with the time when the dose is given, and (3) with the part of the eye which is irritated.

1. *As to the amount.*—Two drops of a ·02 per cent. solution is sufficient to produce a noticeable difference in the size of the pupil, but at least twice that quantity is the minimum which will effect the sensibility materially. If a 2 per cent. solution be used, the effect at the end of about fifteen minutes does not differ materially from that which follows the use of the same quantity of a 4 or 5 per cent. solution. Certainly, the intensity of the effect in the latter case is not twice as great as in the first.

2. *As to the time required for its action.*—From two to six minutes after a full dose some anæsthesia of the conjunctiva appears. The maximum effect is reached in about fifteen minutes, and in thirty or forty minutes commences to subside. When the cocaine has been once applied, subsequent applications apparently act with more rapidity than at first. When the dose is sufficient to produce a well-marked anæsthetic effect, this precedes the dilatation of the pupil. The latter, however, continues for some hours after the former has disappeared.

3. *As to the different parts of the eye.*—The anæsthesia is shown, first, in the conjunctiva and cornea, afterwards in the iris. Its degree is also much greater in these external portions than in the iris. It reaches the latter by passing into the anterior chamber, as can be shown by drawing out from an eye already treated with cocaine the aqueous humour, and dropping that into a normal eye. If a 2 per cent. solution be injected into the anterior chamber, comparatively little irritation is produced, but the degree of anæsthesia, especially in the iris, is not apparently greater than when the same quantity is dropped upon the conjunctiva.

Second in importance to the anæsthetic effect of cocaine is its action as a narcotic. In many of the acute inflammations of the cornea or iris, in abrasions of the conjunctiva from foreign bodies, and in the pain following the use of silver nitrate or cupric sulphate, its influence in this respect is very decided. In the third place, it should be remarked that it acts as a mydriatic. Reference has already been made to this fact. It must be conceded, however, that atropine possesses this quality to a greater extent. Intimately connected with the mydriasis is the paralysis of accommodation. The comparatively slight degree of this, together with the short duration of the mydriasis, is of evident advantage in ophthalmoscopic examinations. Fourthly, the mydriasis is accompanied by a perceptible increase of intraocular tension, as shown by the double manometer of Graser. Fifthly, a slight anæmia of the conjunctiva and enlargement of the palpebral fissure are noticeable within five minutes after the use of a 2 per cent. solution. Sixthly, it does not retard the healing of wounds. Seventhly, watery solutions so complete as to hold no particles in suspension do not irritate the eye. Although not relating immediately to its effects upon the eye, it may be worthy to note, eighthly, that stronger solutions, those of about 5 per cent. and upwards, delay the putrefactive changes in an extract of meat. Ninthly, when cocaine enters the circulation rapidly, the kymograph shows an immediate lessening of the blood pressure, the animal dying with paralytic condition of the heart as one of the chief symptoms.

It is probable that future experience may modify some of the conclusions thus far reached. In the first trials of an apparently useful drug the judgment is apt to be warped by ardent enthusiasm. A fair consideration, however, of facts already well established seems to justify the belief that cocaine is destined to rank as one of the most valuable agents in ophthalmic surgery.

BRIEF NOTES OF

PAINLESS EYE SURGERY BY THE USE OF COCAINE.

BY C. BADER,
CONSULTING OPHTHALMIC SURGEON TO GUY'S HOSPITAL.

CASE 1.—Lady, aged twenty-two. Burnt both corneæ with acetic acid; exhibited extreme intolerance of light and suffered great pain. An ointment composed of chrisma (one ounce) with 2 per cent. of muriate of cocaine was ordered. Immediate relief and rapid recovery followed.

CASES 2, 3.—Aged sixty and sixty-five respectively. Slitting of lower tear puncta and canaliculi. Five, three, and one minute before operating a drop of a 2 per cent. solution of cocaine was applied to the inner surface of the lower eyelids. The patients did not complain during the operation.

CASES 4, 5, 6.—These cases were young ladies with convergent strabismus. The 4 per cent. solution of cocaine was used in one case only to one eye, to note the difference as to pain, which was most striking.

CASE 7.—Tumour removed from upper eyelid. A 2 per cent. solution of cocaine was applied five, three, and two minutes before the operation. No pain was complained of when making the incision, but the patient experienced some pain while I was crushing the tumour.

CASE 8.—Double iridectomy. A 4 per cent. cocaine solution was applied four times in six minutes. No pain whatever at the corneal incision, but the patient felt some pain while the iris was excised.

CASES 9, 10, 11.—Aged forty-five, seventy-five, and eighty respectively. Extraction of cataract by corneal flap without iridectomy; left eye in all. Large hard cataract in the two latter cases. One week after operation the incision was healed; central clear pupil. One case will illustrate the proceedings adopted in the others. I arrived at the patient's house at 3 P.M., and immediately put a drop of a 4 per cent. solution of muriate of cocaine on the inner surface of the left lower eyelid three times in six minutes. At the seventh minute no sensation was experienced by the patient when

Digitized by Google

touching the cornea. The operation was performed in the old-fashioned way, no speculum or fixing forceps being used; central clear pupil; both eyes were bound.

The patient stated that he felt no pain, and seemed much pleased and astonished.

The above cases occurred from October 16th to Nov. 10th. The muriate of cocaine was prepared by Messrs. Allen and Hanburys, 37, Lombard-street, E.C. A fair dilatation of the pupil indicates a more profound insensibility. I believe the future of cocaine to equal that of eserine. In cases of intolerance of light it acts like magic. Its action on the sensitive nerves of the iris must render it valuable to the physiologist. Dr. Koller of Vienna first brought the cocaine before the Ophthalmological Congress at Heidelberg on September 15th, 1884.

London.

COCAINE AS A LOCAL ANÆSTHETIC IN INTRA-LARYNGEAL OPERATIONS.

BY FELIX SEMON, M.D., M.R.C.P. LOND.,
ASSISTANT-PHYSICIAN IN CHARGE OF THE THROAT DEPARTMENT OF ST. THOMAS'S HOSPITAL.

COCAINE has lately been highly recommended as a local anæsthetic in operations upon the eye and throat. Having on my first trial of this new remedy for operations upon the larynx met with very signal success, I think it my duty to record the fact at once for the benefit of others.

I have under my care at the present time a lady with the largest papillomata of the larynx I have ever seen in an adult. The prolonged interference with respiration has so lowered the patient's vitality that on each of the seven occasions on which I have removed masses of the growth by forceps, the mere introduction of the instrument has caused alarming shock. Recently I painted the interior of her larynx with a 20 per cent. solution of muriate of cocaine once, and after waiting five minutes I was able to introduce the forceps four times and remove each time considerable portions of the tumours without the patient experiencing any pain at the moment or subsequent shock. She described the sensations caused by the cocaine as, first, a slight feeling of constriction, followed by a sensation of burning, which quickly passed away.

UNIVERSITY COLLEGE HOSPITAL.

CASE OF HYDROPHOBIA.

(Under the care of Dr. POORE.)

FOR the notes of the following case we are largely indebted to Mr. J. H. Brock, house-physician.

Mary Anne R——, aged thirty, was admitted on Sept. 8th, 1884. It was stated that about a year before the patient had been bitten by a dog on the index and middle fingers of the left hand. About six months later the left index finger had also been bitten by a cat. These wounds healed without difficulty, and soon ceased to attract the patient's attention. It was further alleged that the dog subsequently bit a boy on the shoulder and was destroyed, but there was no distinct evidence that the animal suffered from rabies. Similar evidence was wanting in respect of the cat. The patient and her husband had both been hop-picking and had been indulging freely in drink, and there was a history that on or about the 4th of September the patient was frightened by a dog jumping upon her, but this animal inflicted no bite. On that day (the 4th) the patient complained of some pain in the jaws, and found that they were stiff. On the 6th there was some difficulty in swallowing, and this increased on the 7th, especially when attempts were made to swallow water, and the patient became at times violent and delirious. On the 8th she was seen by Mr. Ingledew, of Woolwich, who, recognising the nature of the case, transferred her to the hospital.

When first seen by Dr. Poore at 4 P.M., about an hour after admission, the patient was sitting up in bed. The face was red and somewhat suffused, and there were superficial abrasions on the cheeks. The colour of the face was partly attributable to exposure to the sun, but the abrasions were caused by the patient trying to allay the irritation of the face by rubbing it with her hands. The expression exhibited considerable excitement mingled with terror, strikingly like that of a hunted animal. The eyes were wide open, and the pupils of medium size and equal. The patient answered questions and appeared sensible, excepting for the fact that she talked almost incessantly, and seemed possessed at times by vague and unreasoning terror. She manifested the greatest unwillingness to make even an attempt to swallow, and positively refused to take a drop of croton oil on butter which was offered to her. On trying to swallow a teaspoonful of milk, which she carried hurriedly and nervously to her mouth, she was seized with a violent spasm of the faucial muscles, which was accompanied by great distress. Whenever the attempt was made to swallow, the same phenomena were observed. Bowels constipated. Tongue somewhat coated. No paralysis or spasm of the limbs or trunk. Temperature 101·4°; respiration 28; pulse 150. It was noted that the knee-jerk was absent in both legs, but that the superficial reflexes were normal.

The patient continued to get more excited and delirious. Her language was extremely obscene, and she constantly stated that she saw various objects, dogs, cats, and human beings, which were all provocative of fear. Towards night she became violent and quarrelsome. At 1 A.M. on the morning of the 9th she asked for water to wash, but at the sight of it she became very excited, and on dipping her hands into it she was seized with a pharyngeal spasm. She gradually got weaker, and at 5.30 A.M. she complained of pain in the legs which prevented her from standing. During the night the urine was passed into the bed. It was noted that while the pulse steadily increased in frequency, the rate of respiration decreased, and at 10 A.M. the temperature was 102·4°, the respiration was only 12, while the pulse was too rapid to be counted. The suffusion of the face steadily increased. At 12.10 P.M. on the 9th the patient had a severe pharyngeal and respiratory spasm, fell back on the pillow and died.

The treatment consisted in the maintenance of surroundings as absolutely quiet as was compatible with the due care of the patient. In addition to this an enema containing sixty grains of bromide of potassium was administered soon after admission, and three hypodermic injections, each of one-third of a grain of morphia, were given at intervals. These had the effect of producing quiet, and affording a little sleep.

The post-mortem examination was made within two hours of death. No change was detectable by the naked eye with the exception of general venous engorgement due to the impaired respiratory power and the mode of death. The necropsy was made as soon as possible in order that "cultivation experiments" might be carried on. It is known that Pasteur has not as yet succeeded in detecting any micro-organism having a definite relationship with hydrophobia. Mr. J. Lister, the assistant of Mr. Watson Cheyne in the biological laboratory of the Health Exhibition, attended the post-mortem, bringing with him a supply of sterilised tubes filled with gelatinised meat infusion. These tubes were inoculated with minute portions of the medulla, the salivary glands, and kidney. Some "growth" has taken place in several of these tubes, but as to the nature of this growth (whether specific or otherwise) no conclusions have as yet been arrived at.

LIVERPOOL NORTHERN HOSPITAL.

EPITHELIOMA OF PENIS; COMPLETE AMPUTATION, WITH FORMATION OF PERINEAL URETHRA; RECOVERY; REMARKS.

(Under the care of Mr. CHAUNCY PUZEY.)

J. H——, aged seventy, was admitted on May 2nd, 1884, suffering from epithelioma of the penis, said to be of only six months' duration. A considerable portion of the glans penis had disappeared, and the body of the organ was evidently involved in the disease, suspicious induration extending as far as the scrotum. The patient's general

Digitized by Google

condition was not very promising; his vessels were very atheromatous, his circulation feeble, and his face injected and dusky in hue; but as he was suffering much from pain and irritation, and as the condition of the inguinal glands was fairly satisfactory, free removal was recommended to and accepted by the patient.

As the man was subject to bronchitis chloroform was given in preference to ether. Two curved incisions were made, one on each side of the penis, from the pubis into the scrotum, dividing the latter freely. The knife was passed round the body of the penis to completely divide its facial envelopes, which could then be freely detached in a backward direction by the finger; the suspensory ligament was divided with scissors, thus freeing the organ from its attachment to the arch of the pubis but leaving the crura undisturbed. The penis was then pulled forward and its deepest exposed part transfixed with a stout curved needle in handle, and beneath this a whipcord ligature was passed and temporarily tightened; the organ was then cut through bloodlessly, the vessels tied, and the tenaculum and ligature removed. The remaining portion of the urethra was detached from its penile attachments, and the perineum having been transfixed with a scalpel was brought through, and, its under surface having been slit up for about half an inch, was stitched to the perineal skin with several silver sutures. A small drainage-tube was passed into the perineal wound (in front of the newly located urethra) and brought out below the pubes, and the scrotal wound was completely closed with metal sutures. The bladder was drained continuously by a perineal catheter to which was attached a piece of tubing long enough to hang over the bed, and into a porringer containing carbolic solution.

There is little to record regarding the after-progress of the case. The patient suffered very little from the effects of the operation, but an enlarged and tender condition of the prostate gland necessitated the removal of the catheter after a few days, and he suffered slightly from cystitis. However, he made a good recovery and left the hospital on June 10th. The wound was then soundly healed, no trace of the penis being left except a slightly depressed cicatrix. He had complete control over his bladder and there was no difficulty in keeping the perineal meatus open.

Remarks by Mr. PUZEY.—I have not seen this patient since he returned to his home in Wales, therefore am unable to report as to his present condition. But last May I had the satisfaction of seeing a patient upon whom I performed a similar operation nearly two years and a half previously, and who is now in perfect health and comfort, in excellent spirits and quite free from any trace of disease.[1] In his case the disease was more extensive, and necessitated the removal of about half the scrotum; the patient was exhausted by loss of blood, by profuse fetid discharge, and by the effects of prolonged retention of urine with enormous distension of bladder, and I certainly did not anticipate such a successful result. In that case the scrotum was divided completely through the line of the raphé, and the incision continued along the perineum; but in that just recorded, the scrotal structures being very lax and the wound therefore distensible, it was found possible to complete the operation in the manner described, the result being less hæmorrhage, probably less shock, and less subsequent call upon the healing powers of nature.

THE NATIVE HOSPITAL, BUTTERWORTH, TRANSKIE, SOUTH AFRICA.

CASE OF A MORPHIA HABITUÉ, SAID TO HAVE TAKEN DAILY FORTY GRAINS OF MORPHIA HYPODERMICALLY; TEMPORARY ABSTENTION; RELAPSE; DEATH.

(Under the care of Mr. J. H. NANKIVELL.)

W. M——, an officer in the Colonial Commissariat Department, aged thirty-eight. About five years ago, when living at the Diamond Fields, he had flying attacks of articular rheumatism followed by severe pain in the left thigh bone about two inches and a half above the knee. Medical treatment proved of no avail and the bone was trephined for supposed abscess without any good result following. After leaving hospital he suffered such agony that on more than one occasion, according to his own account, he drank two bottles of raw brandy before noon. Having been at one time for nearly ten days without sleep he went to a medical man, who gave him a morphia injection. From this time he used morphia subcutaneously in gradually increasing doses, and he stated that during the past eight months his daily allowance has been 480 minims, 12 minims containing 1 grain of the hydrochlorate, or 40 grains a day. Thirty-five minims is the smallest quantity which has at present the desired effect on him. He would sometimes go for nearly a fortnight without a motion of the bowels, as he was much troubled with piles, and then the hard fæces gave him great pain. Shortly before admission he had taken to alcohol drinking, and had at the same time been deprived by accident of his stock of morphia. Mr. Nankivell refused him his favourite drug, put a stop on his supply of alcohol, and admitted him into hospital. For the two days before admission his stomach had rejected every form of nourishment.

On admission, on October 19th, 1882, he was very thin, of a sunken, sallow, muddy complexion, and in a state of great nervous debility and physical exhaustion. Upon the front of the arms, forearms, thighs, and legs were cicatricial spots, as large as the palm of the hand, formed by the constant insertion of the needle. The bowels had not been open for five days. He cried and threatened alternately, and begged constantly for sleep and relief from a cold sensation across the chest. Pulse 54; temperature 98°. No albumen in the urine. Ordered a mixture of subnitrate of bismuth, acacia powder, and spirit of chloroform—a dose just before taking food. During the afternoon he retained two cups of beef-tea and an ounce of brandy, but vomited frequently, bringing up bile, mucus, and a little blood. At night he had thirty grains of chloral hydrate, ten drops of solution of morphia hydrochlorate in chloroform water.

20th.—No sleep all night; very restless and troublesome all day. To have no sleeping draught unless he eats well. Vomited four times, each time bringing up a little blood. Retained a little beef-tea and milk. Bowels opened freely; Stools hard, black, and round, causing in their passage great pain and a good deal of bleeding. Towards night he got into a most abject and pitiable state. At 7 P.M. the draught was repeated.

21st.—About two hours' sleep towards morning; very noisy and troublesome all night. He was told that unless he ate well he should have no more medicine. He took nourishment every hour during the day and vomited twice only. One motion of the bowels, the fæces returning to their natural colour. Ointment of gallic and opium for the piles, which bled freely. At 7 P.M. sleeping draught repeated.

22nd.—A good night's rest. From this time he recovered rapidly, eating well and sleeping fairly with the help of opiates, which were gradually weakened. He left hospital and returned to his work on the 26th, a watch being kept on him that he obtained no more morphia.

Possession was previously obtained of his apparatus, which included four new syringes and a box of needles. On Nov. 24th he handed over four ounces of hypodermic solution of morphia and four ounces of hydrochlorate of morphia, which he had ordered six weeks previously. Four months later he gave way first to drink and then to morphia, from the effects of which he died last year in hospital at Grahamstown.

[1] The case was reported in THE LANCET of July 8th, 1882.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Fatal Hæmoptysis from Bronchial Ulceration.—Ulcerative Endocarditis.—Carcinoma of Stomach in a Girl.—Uterine and Ovarian Disease in Animals.—Hydronephrosis removed by Lateral Abdominal Section.—Bones of Tabes Dorsalis.

AN ordinary meeting of this Society was held on Tuesday last, Mr. J. Whitaker Hulke, F.R.S., President, in the chair. The attendance was numerous.

Dr. PERCY KIDD showed specimens from a case of Fatal Hæmoptysis due to Bronchial Ulceration. The patient was a girl aged fifteen, who had died suddenly from profuse hæmoptysis in the waiting-room of the Hospital for Consumption, Brompton, while under the care of Dr. Mitchell Bruce as an out-patient. The post-mortem examination showed that the air-passages contained blood throughout. Both lungs were marked by patches of inhaled blood, and were studded with small hard nodules. The left apex contained a large cavity, and there were a few small cavities

Digitized by Google

in the lower part of the upper lobe; the small bronchi were generally thickened and slightly dilated. A large firm post-mortem clot filled the main bronchus and the secondary bronchi on the left side. The bronchus leading to the upper lobe had been perforated about half an inch beyond the origin from the main bronchus by ulceration, which also implicated the main bronchus. The ulceration of the bronchus had extended into a secondary branch of the pulmonary artery, causing a perforation as large as a hempseed. A little below and internal to this point there was another perforation of the bronchial wall leading into an irregular space containing a crumbling cretaceous gland. The bronchial ulceration was soft and ragged, and had some of the ordinary characters of scrofulous or tubercular ulceration. The other lung contained no cavities. The bronchial glands were generally cretaceous and slightly enlarged. The stomach contained two pints of blood, but was healthy. The intestines showed slight scrofulous ulceration, the mesenteric glands were enlarged and calcareous, and the liver was slightly amyloid; the other organs were normal. The hæmorrhage in this case was clearly due to perforation of the pulmonary artery by the bronchial ulceration, which in its turn was set up by the presence of an enlarged calcareous gland. The case was an extremely rare one.

Dr. CARRINGTON read a paper on a remarkable case of Ulcerative Endocarditis. The patient was a male, aged twenty-three, who was admitted into Guy's Hospital on April 30th, suffering from acute rheumatism. He had been ill for the previous three months. There was a blowing systolic murmur which suddenly became intensified and harsh on June 11th. The urine, though free from albumen, became and continued to be albuminous and bloody on May 30th, and the temperature ranged between 100° and 103°. At the autopsy there was extreme ulcerative affection of the mitral valve with rupture of many of the chordæ tendineæ. The spleen weighed twelve ounces and a half, contained infarcts, one of which was sloughing. The kidneys were in a condition of acute nephritis and contained many infarcts. Pushing inwards the posterior wall of the stomach at the cardiac end was a hemispherical mass two inches and a half in diameter. This was found to be a false aneurysm, into which the splenic artery opened by its entire calibre. The aneurysm was filled by firm laminated clot. An ulcer without a trace of induration, having for its floor the firm aneurysmal clot occupied the summit of the mass. Recent clot was found round the circumference of the ulcer between the gastric wall and the aneurysmal contents. The stomach contained fifteen ounces of clot. A smaller superficial ulcer was found half an inch off, but not communicating with the aneurysm. In the duodenum a small clot the size of a horsebean was discovered between the mucous and muscular coats bulging the mucous membrane, which was not ulcerated. The case was interesting, for ulceration of the stomach in cardiac disease is rare; and although this fact was undoubtedly a strong argument against the embolic theory of gastric ulcer, the present case might illustrate one mode of formation of gastric ulcer. The three stages seemed to be indicated by the condition of the duodenum without ulceration, and the superficial and deep ulcers in the stomach. Probably the pressure of the effused blood caused local anæmia and allowed of solution of the gastric tissues. Another point of clinical interest which had been dwelt upon by Dr. Goodhart, was that an aneurysm although seemingly cured might bleed between the wall of the sac and its contents. The sudden increase in intensity of the cardiac bruit had enabled a surmise of rupture of the chordæ tendineæ to be made.

Dr. NORMAN MOORE read notes of a case of Carcinoma of the Stomach in a child. The patient was a girl, aged thirteen years, who was under his care in St. Bartholomew's Hospital during March and April, 1884. She was brought to the hospital in a condition of extreme anæmia, with puffiness of the face and œdema of the legs and arms. She was so short of breath that she could scarcely walk. The heart's action was feeble, and there was a loud systolic murmur, best heard at the left base, and accompanied at the apex by a well-marked systolic thrill. There was no albuminuria, and the chief symptom was the recurrence of cardiac distress. She never vomited blood, but two days before death complained of pain in the abdomen, and had several attacks of vomiting. An enlargement of the spleen could be felt. She died five weeks after admission. The autopsy revealed a new growth at the cardiac end of the stomach, close to the œsophagus. The mass measured about three inches in diameter. The peripheral parts arose from the mucous membrane, and were of the same colour, but the central parts were ragged, dark-coloured, and very dense. On section it was seen to be red, with paler stripes. The outer part of the growth was adherent to the liver, but did not penetrate it. There were signs of slight recent peritonitis, apparently due to a tear at the periphery of the growth. No glands and no other organ were infiltrated. There was a very old, perhaps congenital, dislocation of the right hip-joint. The heart was greatly dilated, and contained several adherent, softened, ante-mortem clots, and there was an adherent thrombus in the left jugular vein. This was the earliest example of cancer of the stomach (determined microscopically) on record. It was less dense than such new growths in the gastric wall usually are, but it agreed with them in the absence of secondary deposits. The microscopic characters of the growth were those of a carcinoma with somewhat wide trabeculæ and extensive mucoid degeneration, with hæmorrhages into several parts of the growth. Three distinct stages were visible in the growth. In the least degenerate numerous cells of an epithelial type were collected in large alveoli. In another advanced mucoid changes were observable in the epithelial cells, and in some cells the nuclei had disappeared. In the most degenerate parts almost all the nuclei had disappeared, leaving a mass of mucoid material intersected by traces of the cell boundaries. Having heard from the child's mother that its paternal grandmother had died of cancer at the age of fifty-three, Dr. Moore wrote to Dr. E. D. Wallis, of Leiston, in Suffolk, who informed him that he had made a post-mortem examination on the grandmother in May, 1878, and found a tumour which had obstructed the descending colon. There were no secondary deposits. This growth was probably a true carcinoma, and the early age at which carcinoma of the stomach occurred in his case may be regarded as an example of the well-established law as to the tendency of hereditary peculiarities to appear at an earlier age in the progeny than in the ancestor.—Mr. HENRY MORRIS spoke of a fatal case of cancer of the breast in a woman, whose mother died of cancer many years after her.—Mr. FREDERICK EVE said that the cells in adenoid cancer were generally cylindrical, whilst the cells of Dr. Moore's case were spheroidal.—Mr. HARRISON CRIPPS disbelieved in the hereditary theory of cancer.—Mr. JONATHAN HUTCHINSON said that in his experience whenever cancer occurred at unusually early periods he had found the strongest hereditary history of cancer. In two cases of carcinoma of the testis, occurring in children under the age of one year, he had obtained the strongest evidence of cancer in the family.—Mr. W. HULKE spoke of a case in a lady aged seventy-four, whose elder sister also became cancerous still later in life, whilst their parents died of cancer in early life.—Mr. BUTLIN said that as the grandmother was the only relative known of, there but a slender history of cancer in Dr. Moore's case.—Dr. NORMAN MOORE thought it was well established that some varieties of structure were transmitted to the offspring at an earlier age.

Mr. J. BLAND SUTTON read a paper on Uterine and Ovarian Disease in Amphibia, Aves, and Mammalia. He exhibited a series of specimens which served to show that flexions of the uterus are not confined to the human race. The first was an example of retroflexion in a macaque monkey; the second specimen showed acute anteflexion in a bonnet monkey; the third, acute lateral flexion of the uterus to the right side, also in a monkey. In the last two specimens, the pelvis was considerably distorted, as a result of rickets. Two other specimens, illustrating anteflexion of the uterus, were taken from deer: one from a hyomoschus, which had, a short time previous to its death, given birth to a young one; the other from a molucca deer. The pressure of the anteflexed fundus in the last case had caused atrophy of the anterior wall of the uterus. The uterus of a kangaroo was shown, in which both Fallopian tubes had become greatly distended on account of the accumulation of caseous material in their interior, due to some obstruction of their openings into the uterine cavity. Some of the contents of the tubes had probably leaked into the peritoneal cavity, and had given rise to fatal peritonitis. Mr. Sutton stated that ovarian disease was not uncommon in animals born in confinement, but seemed to be very rare in "wild animals." He observed that it had long been shown that some cysts in the broad ligament frequently arose from abnormal distension of the tubules forming the "organ of Rosenmüller" (the parovarium). He had made an investigation with a view to determine how far the notion of cystic dilatation of tubules

Digitized by Google

having no functions held good. The results, briefly stated, were that male toads possess the remains of Müller's ducts in a well-marked degree; and it was no uncommon thing to find these ducts, which in the male toad had no function, dilated in their lower third into cysts, some very small indeed, but others of considerable size, and affording indisputable testimony to the origin of cysts from pre-existing ducts. About 250 frogs and toads were examined to test the point, and about ten well-marked examples of the cyst were found; they were, as a rule, arranged symmetrically. In birds, as in frogs and toads, upon the Müllerian ducts devolved the duty of conveying the ova from the abdomen to the outer world. In the embryo chick there were normally two oviducts; but the left duct alone persisted, whilst the right one usually disappeared, though now and then a small rudiment of the lower end, from a quarter of an inch to an inch long, remained attached to the cloaca. It might become the seat of cystic change, and in some cases assumed considerable proportions. The occurrence of these cysts was by no means unfrequent; and their presence was injurious, for a cyst might become detached, and set up fatal peritonitis. A curious fact, first pointed out by Hunter, was occasionally noticed; a hen bird would lay aside the sober plumage of her sex, and take on that of the cock. This fact had been attested by several naturalists of eminence; and Mr. Sutton exhibited a drawing of a hen golden pheasant now living in the Zoological Society's Gardens. Two years ago she assumed the resplendent dress of the male bird, the only difference being that there was no white rim to the pupil, and no spurs. She lived quite happily with her mate, and they did not fight. This singular change was always associated with disease of the ovaries or the oviduct. In mares, cysts in the mesosalpinx were so frequently found that in fifty old mares, taken at random, two-thirds possessed cystic ovaries, the cysts varying in size from a grape to an orange, and in number from three or four to a dozen. Careful examination of these cysts had convinced him that they arose by dilatation of the tubules of the parovarium, brought about by the increased blood-supply to the ovary in old age, due to the dilatation of the ovarian veins, much as was seen in the prostate of men advanced in life. Among other animals, he had met with cystic ovaries in a tiger that was born in this country and lived in confinement for twelve years. The cysts were small, numerous, and pedunculated, resembling the incipient cysts so frequently seen about the ovary and Fallopian tubes in virgins. Cystic tumours were also shown from a cat, a goat, and a tree-porcupine. He had brought these facts before the Society, not as mere curiosities of disease occurring in animals, nor as interesting in that they illustrated truths which might *a priori* have been anticipated, but because they demonstrated, unquestionably, that there was a strong tendency for ducts having no function to dilate into cysts.—Mr. ALBAN DORAN observed that in the human female atrophy or removal of both ovaries was not invariably followed by loss of the attributes of femininity. In examining the hypertrophied broad ligament attached to ovarian tumours he had observed that large or small thin-walled cysts were often developed between the layers of the broad ligament far from the parovarium and even above the Fallopian tube. Yet such cysts were certainly developed, in other cases, from the extremity of the horizontal duct of the parovarium. Cysts of the vertical tubes of that structure of the hilum of the ovary and of Gärtner's duct always appeared to contain papillomatous growths. There was no doubt that the parovarium existed in woman as a part of the Wolffian body, that Gärtner's duct was generally persistent though impervious, and that the duct ran into the walls of the uterus, passing through the cervix, and then entering the cellular tissue of the vagina, where it ended in a blind extremity. Sometimes it made a turn on itself and ended in the same manner in the cervix, not reaching the vagina; this variation depended upon the extent to which the lower part of the fused Müllerian ducts developed into uterine, at the expense of vaginal structures. The pair of tubes in the walls of the human female urethra lead to ducts and have probably nothing to do with Gärtner's ducts. These "Skene's tubes" were subject to catarrhal affections.—Dr. DAWTREY DREWITT referred to the acquisition of male characteristics by female birds in whom there was disease of the ovaries or oviducts.—Mr. FREDERICK EVE spoke of large tumours formed at the expense of persistent Müllerian ducts. The hydatid of Morgagni about the epididymis was generally believed to be the dilated upper extremity of Müller's duct. Many encysted hydroceles of the testicle were derived from the organ of Giraldès.—Mr. SUTTON, in reply, said the cysts contained clear coagulable fluid but no papillomata. The remains of the Wolffian bodies in the hilum of the ovary might be the source of origin of papillomatous growths. Gärtner's duct might develop a cystic growth about its termination near the vagina.

Mr. KNOWSLEY THORNTON showed a specimen of Hydronephrosis due to Calculus, removed by Langenbuch's operation. The patient was a single woman aged thirty-two, who when first seen had an abdominal cystic tumour; she had enjoyed fairly good health till about two months before October, when the abdomen was found to be much enlarged and tender; an exploratory operation was made and the diagnosis arrived at. She had had pain in the right loin since eight years of age, and renal colic accompanied by sharp hæmorrhage occurred nine years ago. The urine was passed in normal quantity, was clear, pale, acid, and of a specific gravity of 1020, but contained no albumen. On Oct. 8th the lateral operation was performed and the ureter drawn out at the lower angle of the wound. Before removal of the kidney three pints of urine were drawn off, which contained a trace of albumen, had a specific gravity of 1015, and was slightly cloudy; an oval brown calculus was found on a bed of papillomatous tissue obstructing the ureter. The renal tissue was almost entirely destroyed over the whole of the renal cyst. This was the ninth successive case in which the abdominal operation had been successfully performed. The specimens of the tenth and eleventh cases were also shown. No cause could be assigned for the eleventh case. In the ninth case the left kidney was felt to be much enlarged along the side of the lumbar spine.

Mr. J. HOPKINS showed specimens of Bones from two cases of Tabes Dorsalis. Of the first case the upper end of a femur with old fracture of the neck presented changes identical with rheumatic arthritis. The patient had well-marked signs of tabes; the movements of the right hip-joint were too extensive, and gave rise to no pain; the right knee-joint was distended with fluid. During the three years the case was under treatment there were lightning pains and daily vomiting, but no gastric crises; the use of morphia aggravated the symptoms and caused vivid illusions, which later in the case became a marked feature. Muscular tremor and general wasting, together with bulbar symptoms, set in towards the close of the case. There was optic neuritis in the left eye, with concentric loss of vision. Of the second case the femur and articular ends of bones forming the knee and ankle-joint presented irregular cartilaginous surfaces, due to past ulceration and wearing down of cartilage. A ring of new cartilage, partly ulcerated, was to be seen round the head of the femur. There was a well-united fracture of the femur. The patient had suffered from lightning pains, but never vomiting. Bulbar symptoms were observed from time to time during three years. There was effusion into the right ankle-joint, which lasted six months; a spontaneous fracture of the left femur remained ununited after being kept in splints for three months. The patient had had optic neuritis of the right eye. There were well-marked symptoms of disease of the bulb at the time of death.

The following card specimens were shown:—Dr. Hebb: Sarcoma of Spinal Cord and Bacilli in Primary Cancer of Liver. Dr. Turner: Laceration of Kidney, with Aneurysm of the Renal Artery. Dr. Edmunds: Hypertrophy of Tibia. Mr. K. Thornton: Cystic Kidney and Scrofulous Kidney removed by Abdominal Operation. Mr. Arbuthnot Lane: Fracture of Sternum. Mr. Hutchinson: Diffuse Morphœa of Hand with Gangrene of Finger.

The following recent specimens were exhibited:—Mr. Rickman Godlee: Fracture of Skull with Effusion of Serum. Dr. Hale White: Primary Encephaloid Cancer of Liver; Ulceration of Trachea from Tracheotomy Tube.

Mr. Davies Colley showed a living specimen of Spondylitis Deformans of Dorsal Region.

CLINICAL SOCIETY OF LONDON.

Dysentery treated by Voluminous Injections of Nitrate of Silver.—Charcot's Disease.

AN ordinary meeting of this Society took place on Nov. 14th, Sir Andrew Clark, Bart., President, in the chair. The discussion on Mr. Morrant Baker's paper was adjourned till the next meeting.

DR. STEPHEN MACKENZIE read a paper on Cases of

Digitized by Google

Chronic Dysentery treated by Voluminous Enemata of Nitrate of Silver. The author alluded to a former series of cases he had brought before another Society, and stated that extended experience had strengthened his belief in the value of large enemata of nitrate of silver in the treatment of cases of chronic dysentery or dysenteric diarrhœa. The mode of procedure he adopted was as follows:—The quantity of nitrate of silver to be used was dissolved in three pints of tepid water in a Leiter's irrigating funnel, which was connected by indiarubber tubing with an œsophageal tube with lateral openings. The patient was brought to the edge of the bed and made to lie on his left side with his hips well raised by a hard pillow. The terminal tube, well oiled, was passed about eight or ten inches into the rectum, and the fluid allowed to force its way into the bowel by gravitation. The injection rarely caused much pain, and often none. It usually promptly returned, but when long retained it was advisable to inject chloride of sodium to prevent absorption of the silver salt. Various strengths had been used, from thirty to ninety grains to three pints of water, but usually one drachm of nitrate of silver was employed. The treatment was based on the view that, whatever the nature of dysentery, whether constitutional or local in the first instance, the later effects were due to inflammation or ulceration of the colon, which was most effectually treated, as similar conditions elsewhere, by topical measures. Sometimes one injection was required and sometimes two, and in some cases numerous injections were necessary; but in all the cases thus treated, many of which had been unsuccessfully treated in other ways previously, the disease had been cured. In most cases other treatment was suspended, but in some Dover's powder or perchloride of iron, which had been previously administered, was continued or subsequently prescribed. Six cases were narrated. In the first the disease had lasted several years off and on; two injections were used and the case was cured in six weeks. The second case was a second attack of dysentery of uncertain duration; four injections were used, and the case got well at the end of five weeks. The third case had lasted two months; two injections were used, and the case was cured in three weeks and a half. The duration of the fourth case was five years; one injection was used, and the disease was at an end in three weeks. The fifth case lasted eighteen months; two injections were used; the dysenteric symptoms disappeared, but the patient remained under treatment for diabetes. The duration of the sixth case was fourteen months; one injection was used, and a cure was effected in seven weeks. The treatment, which laid no claim to novelty, was brought forward to elicit the experience of others who had tried it, or to induce others to employ it in suitable cases.—Dr. CARRINGTON doubted whether on further experience such favourable results would be repeated. At the Seamen's Hospital he had much experience of dysentery. He supposed that it was the voluminous nature of the injection for which the value of the treatment was claimed. He had employed injections of one pint without any marked effect on the disease. To him it seemed incredible that the severe lesions of dysentery could be cured by such a moderate amount of treatment. Moreover, it was probable that as much as six pints would be required to fill the colon.—The PRESIDENT said that the use of voluminous injections was known to the ancients. Dr. Mackenzie had clearly shown that the use of voluminous injections of nitrate of silver was of great value under certain circumstances.—Dr. CULLIMORE asked whether the treatment advocated by Dr. Mackenzie had any advantages over other methods of treatment; were the cases cured in a shorter space of time? He considered that perfect rest, a proper dietary, and removal from their former mode of life, were the most important matters to attend to in the treatment. He referred to one case in which the injection of a solution of nitrate of silver caused a considerable amount of pain along the course of the colon. He had seen a case which led him to believe that starvation might be sufficient to cause the disease. Injections of iodoform were used, but opium and tincture of krameria did far more good.—Dr. DYCE DUCKWORTH said that he had treated but one case, and in this the results were not very remarkable. The case was a moderately severe one, involving the colon and sigmoid flexure. He could not but think that cases which were called dysentery varied much in etiology and pathology. The influence of temperament and diathesis in tropical diseases was one which required to be a good deal more recognised than was at present the case.—Dr. BERNARD O'CONNOR asked how long a time had elapsed since the above results had been obtained. He had known hot water injections to cure the disease.—The PRESIDENT asked the author to state the mode in which the injections were used, and to describe the character of the stools before the treatment was begun.—Dr. STEPHEN MACKENZIE, in reply, said that the account in his paper would answer most of the questions. Many times in his paper he used the terms chronic dysentery or dysenteric diarrhœa. These names related to a condition which those who had had acute dysentery at some time might suffer from. The patients were greatly emaciated, and there was much anæmia, with dryness of all the mucous membranes. In cases of slighter ulceration, he believed that this method of treatment would be found to be far more effectual than other modes. He had noticed that the same class of cases came to the London Hospital as went to the Seamen's Hospital at Greenwich; amongst them were cases of various degrees of chronicity and severity. He had seen a single injection cure a case of dysentery which was complicated with cbyluria. It was impossible for him to speak as to the permanency of the cure in the class of patients who were under his care: He ventured to think that distension of the colon was not required, and might be dangerous; three pints was a good quantity to inject, and seemed to effect all that was necessary.

Mr. MORRANT BAKER read a paper on three cases of Joint Disease in connexion with Locomotor Ataxy. The paper was illustrated by casts and specimens. The patients were two males, aged respectively forty-six and fifty-six; and a female, aged fifty-four. In all, the symptoms of locomotor ataxy were well marked, the disease having existed in one case for about two years, in another for a few months, and in the third for twenty years. In the two men the joint chiefly affected was the right knee-joint; in the female the right elbow-joint and both hip-joints, with incipient disease of the left elbow-joint, were the diseased parts. In all the cases the disease of the joints was apparently a typical example of the affection usually termed Charcot's disease. The joints were much enlarged, the articular surfaces greatly misshapen, and the ligaments weakened or destroyed. There had been very considerable wearing away of the articular ends of the bones—one or other condyle and a large portion of the head of the tibia in the case of the knee-joints, and apparently nearly complete disappearance of the heads of the femora in the case of the hip-joints. The joints were loose and flail-like; although in the case of the diseased elbow-joint, and in those of the knee-joints, the patients retained considerable power of voluntary movement. Mr. Baker remarked that he had brought the cases before the Society chiefly in order to add to the record of facts regarding a rare and not well-understood disease; but he thought a discussion might well be raised in connexion with them on the following points:—(1) Whether the disease is actually new? (2) What are its alliances, if any, with rheumatoid arthritis? (3) If connected with the last-named disease, is its occurrence in conjunction with locomotor ataxy a mere coincidence? or do these stand in the relation, one to the other, of cause and effect; and (4) if connected pathologically both with rheumatoid arthritis and with locomotor ataxy, should not all cases of rheumatoid arthritis be considered of neurotic origin, whether accompanied or not by symptoms of locomotor ataxy? There is still another theory possible, even if Charcot's disease and locomotor ataxy and rheumatoid arthritis are all connected in pathological origin. It is conceivable that all arise from some antecedent diseased condition of which the result is expressed in pathological changes, sometimes in the cerebro-spinal nervous system, sometimes in the joints, and sometimes in both.—Mr. ARTHUR E. BARKER related the case of a man aged thirty-eight, a railway porter, who came to him suffering from urinary troubles, the chief of which was increased frequency of micturition; the disturbance of the act of micturition was most evident when the bowels were loaded. Much nausea with curious feelings, and even vomiting with pain in the epigastrium and a feeling of distension about the abdomen, were complained of. Numbness in the feet and attacks of "rheumatic" pain in the limbs were experienced sometimes. The first symptoms began in January, 1881, and later a perforating ulcer appeared in the sole of the right foot, but, with the above exceptions, there were no other symptoms of ataxy, as Drs. Gowers and Barlow testified on different occasions. A second ulcer on another part of the sole of the foot appeared a few months after the first. Both these ulcers were benefited by treatment, and the patient was

Digitized by Google

lost sight of for a time. When next seen gastric symptoms were again dominant, and the ulcers on the right foot had taken on fresh action; it was also noticed that the foot was much worse after the gastric attacks. With a variable course the case went slowly on, when at the beginning of the present year complaints of shooting pains in the left thigh and quivering of the muscles were recorded. A feeling of sudden weakness was from time to time experienced. Soon one of the knee-joints underwent complete disorganisation. The tibia was dislocated inwards and a little backwards. Yet all through this time, and up till the present date, the knee jerks were present; there were no ocular phenomena, and none of the ordinary objective phenomena of tabes dorsalis.—Dr. DYCE DUCKWORTH implied that the view which referred the joint disease to the class of ordinary rheumatic arthritis was not accepted by him. He believed that Charcot's disease was a definite form of joint-disease distinctly associated with disease of the nervous system. Clinically, the course of the two diseases above mentioned was very different. If we remembered that in the course of a few weeks an amount of destruction existed such as was not seen in ordinary cases of rheumatic arthritis after the lapse of twenty years, he did not perceive how confusion between the two diseases could arise. He was of opinion that an acute observer of such long experience as Charcot was hardly likely to fall into error on this question. The joint change was not due to injury and was not like an ordinary arthritic affection. Referring to pathological appearances, he said that if there were one creed in medicine which was more axiomatic than another, it was that which believed that identity of lesion was by no means a proof of identity of process which had led to it.—Dr. HALE WHITE said there must be something radically wrong if an acute observer like Moxon could assert that out of thirty cases of tabes dorsalis there did not happen to be one of joint disease, when it was recollected that one in every ten was the proportion given by Charcot. He referred to a case which he had discovered in the post-mortem room where the temporo-maxillary articulation presented changes perfectly indistinguishable from those ascribed to Charcot's disease, whilst all the other points were unmistakably examples of rheumatic arthritis. He thought there were many points in common between the two maladies; examples of the two cases were mixed up, and there were so many connecting links between the two that the opinion that Charcot's disease was rheumatic arthritis modified by the special conditions of the disease was probably the correct one.—Dr. BUZZARD thought that although we had no proof, yet the probability was that the disease was not new. He had searched through Graves' work, which antedated Romberg's or Duchenne's account of tabes dorsalis, and there discovered an account of a case characterised by typical gastric crises which was without doubt one of locomotor ataxy; and this occurred as long ago as 1823. Further, it must be remembered that cases were so little recorded in earlier times, that an enormous increase of population had occurred, and that till within the past fifty years or less there were no out-patients to our hospitals, and so it was not strange that we should come across many more cases in proportion than would have been met with many years ago. It was in 1868 that Charcot described a case of joint affection alone, and it was five years later when a case with disease of several joints and with spontaneous fractures of the long bones was published by him. That observer believed that the osseous tissues were primordially involved in these cases, and that the joint disease was a part of the osseous alteration. Lionville investigated the subject by comparing a case of arthropathy associated with tabes dorsalis and a case of spontaneous fracture of the bones occurring in locomotor ataxy. He found that the same changes pertained in each instance. There was dilatation of the Haversian canals, with remarkable thinning and erosion of the bones. Regnard investigated the bones from a chemical standpoint, and found that the mineral substance was reduced from 48 to 11 per cent., and that the fat rose from 5 parts to 37. Dr. Buzzard suggested that surgeons should measure the specific gravity of the bones entering into the formation of the diseased joint with a view to possibly distinguishing between Charcot's disease and rheumatic arthritis; the specific gravity would probably be found to be greatly diminished in the former. In Dr. Adams' classical work on Rheumatic Arthritis no mention is made of such changes. It was to the surgeons that cases of joint disease naturally went, and though he had seen some hundreds of cases of tabes dorsalis, yet he could almost count on the fingers of his hands the number of cases of joint disease which had come to consult him amongst the sufferers from tabes dorsalis. He opined that a suddenly occurring painless swelling of a joint would not lead its possessor to go to a physician. Dr. Charcot's opportunities at the Salpêtrière were different from those of a physician to an English hospital. The patients included such as are found in our workhouse infirmaries, and they remained for years under observation. These considerations afforded a complete explanation of Dr. Moxon's experience. Having had to do with a large number of cases of nervous disease in the out-patients, as well as in the in-patients, of a hospital devoted to nervous diseases, it was not strange that he (Dr. Buzzard) should have met with several cases of associated joint disease, and yet in every such association the nervous disease was found to be tabes dorsalis. On the other hand, he had watched cases of rheumatic arthritis for years, and they never developed the symptoms of tabes dorsalis. He had investigated a great many cases of rheumatoid arthritis in English infirmaries, and, except where the mechanical conditions prevented him from testing it, he found the knee-jerks always present and the ocular phenomena natural. He considered that Charcot's disease contrasted clinically in the strongest manner with rheumatic arthritis.

The following living specimens were shown before the meeting:—Mr. Malcolm Morris: A case of Favus from Lisson-grove. Dr. Radcliffe Crocker: Atrophy of the Scalp from Favus of long standing. Mr. A. E. Barker: Intra-uterine Constrictions of Lower Limbs. Mr. Morrant Baker: Charcot's Disease. Mr. Anthony Bowlby: Joint Disease and Locomotor Ataxy. Mr. R. W. Parker: Two cases of Spina Bifida. Dr. Charlwood Turner: Charcot's Disease. Dr. Donkin: Muscular Atrophy and Osseous Disease.

MEDICAL SOCIETY OF LONDON.

Koumiss.—Conduction of Physical Signs.

AN ordinary meeting of this Society took place on Monday last, Mr. Arthur E. Durham, President, in the chair.

Mr. NOBLE SMITH exhibited a case of cured Meningocele of the Occipital Region, treated by iodo-glycerine (Morton's fluid), in a child aged eleven months.

Dr. CARRICK read a paper on Koumiss. He drew attention to the similarity between asses' milk, mare's milk, and human milk. A table contrasting the cow's milk with woman's, mare's, and asses' milk was drawn up, from which it was shown that the reaction of the larger group was always alkaline, whilst the cow's milk was neutral or slightly acid. The casein of the larger group occurred in thin flakes; that of cow's milk in thick, compact, lumpy masses. When dried the casein of the larger group was granular and soluble in water and coagulable by neutral salts—e. g., sodium chloride; casein from cow's milk when dry was horny and almost insoluble in water and not coagulable by sodium chloride. Cow's milk could be churned into butter, but this was not the case with the milk of the larger group. The subjective symptoms due to a diet of koumiss were described in detail, and the effect of such a diet on the chemistry of the body was entered into. Koumiss was of much value in all diseases associated with wasting and in many kinds of ulceration of the bowels. Its powerful diuretic action might prove of use in cases of renal disease. In cardiac disease koumiss was most valuable. But consumption was the disease *par excellence* in which koumiss effected so much good.—Dr. JAGIELSKI had introduced koumiss into this country fifteen years ago. Clinical experience led him to believe that koumiss made from cow's milk was as good as that made from mare's milk. It was necessary to remove part of the casein and part of the fat and to regulate the amount of sugar.—Dr. THEODORE WILLIAMS said that Dr. Burdon Sanderson had not formed a very good opinion of the use of koumiss in consumption. He had tried it in many diseases associated with vomiting with marked benefit.—Dr. CULLIMORE thought the climatic conditions had much effect in the koumiss cure in the steppes of Russia.—Dr. EDMUNDS understood that the author only claimed koumiss to be a nutritive agent of extraordinary power. New milk was known to be more digestible than milk that had stood for some time.—Dr. CARRICK said that koumiss was fermented mare's milk and not fermented cow's milk.

Dr. MARKHAM SKERRITT (Clifton) read a paper on the

Conduction of Physical Signs in Diseases of the Lungs. It was universally recognised that the lung tissue acted as a conducting medium for physical signs in heart disease, but it was not so fully appreciated that the physical signs of lesions of the lungs themselves might be detected at a distance from their source. It might be stated (1) that physical signs due to disease of a limited portion of lung were liable to be conducted by the adjacent tissue so as to be recognised at a distance from the site of the lesion—as in front when the disease was at the back, or on the sound lung when one lung only was affected; (2) that it was therefore as important to trace to their origin the physical signs dependent upon lung disease as it was to follow out those of a cardiac lesion. Instances were adduced of the adoption by a consolidated lung of the signs of pneumothorax derived from the opposite side: the transmission to the sound side of the tubular breathing of pneumonia, the interchange of physical signs between the affected side and the unaffected in pleuritic effusion, the conduction of the physical signs of phthisis, from one apex to the other, and the conveyance throughout the pulmonary region of sounds having a strictly localised origin. The physical signs most liable to conduction were those of auscultation; and of these, chiefly rales and altered breathing. In the localisation of a conducted sign in lung disease the process was the same as in the case of a cardiac lesion. In conduction a physical sign (1) retained its special quality; (2) lost in quantity in proportion to the distance from its source. The readiness with which a physical sign was conducted was also of value as an indication of the state of the transmitting tissue. The subject of the paper was one of considerable practical importance, as instances had been met with where error had resulted from the want of a due appreciation of the facts adduced.—Dr. THEODORE WILLIAMS remembered several instances in which it had been difficult to arrive at a correct diagnosis from physical signs being conducted away from the place at which they originated.—Dr. DE HAVILLAND HALL thought that the auscultatory signs over the lung ought to be checked by palpation, percussion, and auscultation of the vocal sounds. He referred to the possibility of conduction by means of a thickened pleura or enlarged mediastinal glands.—Dr. COUPLAND thought there was some novelty in the belief that the physical signs of phthisis might be conducted to the healthy lung, and related a case of asthma bearing on the subject.—Dr. KINGSTON FOWLER said it was very common to find that the physical signs of a cavity at one apex of the lungs were conducted to the opposite apex. It was necessary to verify the auscultatory signs by other methods of physical examination.—Dr. SKERRITT briefly replied.

OBSTETRICAL SOCIETY OF LONDON.

A MEETING of the above Society was held on Wednesday, Nov. 5th, Henry Gervis, M.D., President, in the chair.

The following specimens were shown:—Mr. Sydney Jones for Mr. Lawson Tait: Tubal Fœtation. Mr. Thornton: Fibroid Uterus, with two Cystic Ovaries, removed by operation. Dr. Aveling: Fibroid of Uterus, with Cystic Degeneration, removed by operation. Mr. Walter Griffith: Retroverted and Adherent Uterus, with two Prolapsed and Adherent Ovaries. Dr. Bantock: Hagedorn's Surgical Needles and Holder. Dr. W. Duncan: Double Intra-uterine Tube. Dr. Godson: Greenhalgh's Spring Pessary, with Glycerine Pad.

A plea was raised for the revival of Toughened Glass Specula by Dr. Heywood Smith.

A paper was read on the Severe, or so-called "Uncontrollable," Vomiting of Pregnancy, by Dr. GRAILY HEWITT. Although many theories of the cause of the severe, or so-called "uncontrollable," vomiting of pregnancy have been put forward, the profession has not adopted any of them. The author's object in the present paper is to investigate the question as to the influence of morbid conditions of the uterus in giving rise to the disease. The facts and cases published and available for discussion of this question are now arranged, and tabulated, and analysed. The first series of cases are thirty-two in number, and include all cases the author has been able to collect in which the condition of the body of the uterus was noted and observed in cases of severe vomiting in pregnancy. In a second series of cases, thirteen in number, the condition of the os and cervix uteri was particularly noted and described. These two series of cases constitute the clinical data available for use in the discussion of the question as to the influence of the condition of the uterus itself in causing the vomiting, and they include 10 cases observed by Prof. Horwitz of St. Petersburg, 8 recorded by the author, 7 by Dr. Copeman, 2 by Stoltz, 2 by Dance, and single cases recorded by other authorities. In the series of 32 cases there are 28 cases of a very typical description, in which sickness of an intense degree of severity was present in the course of the first half of pregnancy. In the majority of these 28 cases the vomiting was so severe that the question of artificial abortion arose. In 23 of these cases the uterus was in a state of decided anteversion or anteflexion, and in 12 of these 23 cases there was impaction of the anteverted or anteflexed uterus in the pelvis. In one case the uterus was anteverted slightly, but had been considerably anteflexed shortly before the pregnancy occurred. In 4 of the 28 cases the uterus was retroverted. It thus appears that out of the 28 cases in question the uterus was decidedly altered in shape and position in 27 cases, and in the one case remaining was anteverted slightly. The cervix was thickened and unduly hard in 3 out of the 32 cases, and much thickened in 6 cases. In the other series of 13 cases the cervix was described as very hard in 4 cases. In 2 cases (of the 32 series) pus was found between the uterus and decidua after death. There was excessive sensitiveness of the uterus in most of Horwitz's cases, and in 4 or 5 what Horwitz terms parenchymatous inflammation. The remarkable feature in the series of 32 cases is that in all the cases where attempts were made to raise the uterus from its displaced position, and when that attempt was successful, the vomiting ceased, whereas when the attempt failed the vomiting continued and the patient died, the exceptions being those in which artificial abortion was induced, and one in which abortion occurred naturally. In some of the cases artificial abortion was had recourse to as a primary procedure. Of the 32 cases, 11 died, 20 recovered, and in 1 the result was not known. The 20 recoveries include 6 after induction of artificial abortion, 1 natural abortion, 7 after manipulative treatment and replacement of the uterus, and 6 following positional treatment, rest, anti-inflammatory remedies, &c. The second series of 13 cases were, with one exception, cases in which the new treatment suggested by Copeman was carried out, and in which no record is given as to the state of the body of the uterus. In these 13 cases recovery took place. The author concludes: (1) That the cases in which the disease is due to some other organ than the uterus are so few in number (only 1 in the series of 32) that they may be almost excluded from consideration. (2) That in the large majority of cases the disease presents itself during the first half of pregnancy. (3) That the evidence points to interference with the normal expansion and growth of the gravid uterus as the condition of the production of this dangerous affection, and that this is most frequently brought about by or in connexion with detention of the bulk of the uterus in the bony pelvis, in 88 per cent. the uterus being anteflexed or anteverted, and in 12 per cent. in a state of retroversion; the other conditions met with being hardness, resistance, or unusual rigidity of the os and tissues of the cervix. (4) There appear to be two factors to be considered capable of interfering with the expansion of the uterus: (*a*) incarceration with flexion or version; (*b*) undue hardness and rigidity of the os and cervix; these may be conjoined in a given case. It appears to be borne out by the facts recorded that the incarceration is the more important of the two factors as a rule at least. The facts appear to point to the occurrence of embarrassment in the expansion of the uterus very early in the pregnancy, such as might be expected to be occasioned by a previously flexed state of the uterus, or to a congested indurated state of the cervix, or to the two conditions combined. As the pregnancy advances the congestion and swelling are intensified and the resistance to expansion thus increased. It appears probable that the particular cause of the sickness observed is the compression of the nerves situated in the tissues which are especially exposed to compression—viz., those around the cervix uteri and especially those near the internal os. Copeman's success in the treatment of severe sickness by dilating the internal os is evidence in this direction. The importance of the flexion element has been denied, one principal objection being that sickness is not always present when the uterus is flexed. But the case is the same in the non-gravid uterus; severe sickness is not seldom due to flexion of the non-gravid uterus, while flexions are observed without sickness. Corroboration of the author's views are contained in Gebrung's

Digitized by Google

recent paper. As a rule severe sickness is limited to the first half of pregnancy, in a very few cases it persists longer; in these rare cases the cause may be rigidity of the tissues round the internal os, persisting to a late period. As regards treatment the first indication is to secure the normal upward movement of the fundus uteri, to relieve the incarceration of the uterus when present, if that be possible, and to prevent its occurrence by a properly arranged method of treatment. Absolute rest in the supine position if anteversion be present, or on the face or side if retroversion be present, and the use of the knee-elbow position will be required. These measures suffice in many cases. If the uterus be fixed gentle continuous pressure must be applied internally by the fingers or by an air-ball and the position maintained by a suitable pessary. These measures failing, Copeman's procedure of dilating the cervix should be employed. The last alternative, induction of artificial abortion, will, it is believed, be rendered unnecessary if the other less severe measures are applied sufficiently early.—The discussion, which was adjourned soon after its commencement, will be given in the notice of the next meeting.

ABERNETHIAN SOCIETY.

AT the meeting held on Thursday, Nov. 13th, Mr. O. LANKESTER and Mr. STEPHEN PAGET read short papers on Infantile Diarrhœa and Abdominal Abscesses respectively. Mr. Lankester's paper treated of simple diarrhœa, unconnected with organic disease of the intestine. He divided the subject into the four varieties of (1) non-inflammatory, (2) inflammatory, (3) choleraic, and (4) dysenteric. Of these four, he discussed only the first two varieties. He mentioned cold, bad feeding, dentition, and worms as the chief causes, and sketched out the diet of infants. He mentioned the complications of diarrhœa—as blood in the stools and prolapse of the rectum; and spoke of the use of opium in the latter complaint. Mr. Lankester next alluded to the uncertainty of diagnosis in cases of diarrhœa caused by dentition. With regard to the inflammatory diarrhœa, the causes may be the same as those of simple; also bad smells. In considering the question of diet, he spoke of the necessity of avoiding milk, and advised the substitution of broth; also white wine whey in cases where collapse is present. He alluded to the use of mustard baths and brandy, to the antiseptic treatment, washing out the stomach, and administering small doses of benzoate of soda frequently. In chronic forms of inflammatory diarrhœa, the utmost attention should be paid to diet, and pepsin and raw meat were very useful in such cases.

Mr. STEPHEN PAGET, in discussing Abdominal Abscesses, divided the subject according to the causes. 1. Injury or disease of the wall itself: (*a*) contusion; (*b*) tracking of discharge from a non-penetrating wound; (*c*) injury or disease of bones or muscles; (*d*) inflammation of the connective tissue between the muscles. 2. Inflammation of the sub-peritoneal connective tissue. 3. Injury or disease of internal organs. 4. Deep-seated cancer. Mr. Paget mentioned some extraordinary cases which have been recorded from time to time, and also the frequency of abscesses following necrosis of a rib from scrofula or typhoid fever. He next discussed the nature and appearance of phlegmonous inflammation of the connective tissue, and cases were cited showing its causes, and also its course under treatment.

Mr. PAGET brought forward three cases of Pelvic Abscesses in young women which were treated by puncture or incision through the abdominal wall, and also three cases of Deep-seated Abscesses of the Subperitoneal Connective Tissue incised above the pubes and drained. Lastly, six cases were given of Abscesses of the Abdominal Wall due to Deep-seated Cancer. In conclusion, Mr. Paget urged the necessity of treating all acute abscesses of the abdominal wall as soon as possible and by incision rather than by puncture, and impressed upon his hearers the fact that in elderly people the cause is frequently cancer.

GLASGOW UNIVERSITY MEDICO-CHIRURGICAL SOCIETY.

Address by Professor Gairdner.

THIS Society, established and maintained by the students of the university for the purpose of mutual improvement and the reading of papers and discussions during the session, met on the 14th inst. to hear the address of the annual honorary president, Professor W. T. Gairdner, M.D., LL.D. Dr. Joseph Coats, the retiring honorary president, took the chair, and was supported by Dr. Rutherford, the acting president; Mr. John M'Phail, vice-president; and other office-bearers, together with Dr. Lindsay Steven, a former president. Dr. Gairdner's address, as announced, was on "The Self-Education of the Medical Student." On this subject he said that the purpose of the address, which, he feared, must after all be very unequal to his intentions and to his hearer's goodwill, was to make a few reflections or suggestions as to what he had termed "self-education"—meaning thereby something outside the regular discipline of the curriculum, and yet not so entirely removed from professional work as to be even apparently foreign to, and apart from, it; in other words, not the more general—moral, religious, ethical—discipline which is usually implied in "self-culture," as, for example, it has been admirably treated in a little book by his friend Professor Blackie. Professor Gairdner's aim was to show that, even in the midst of the medical education, so called, which is laid down in the curriculum, and which is therefore compulsory, and may be even felt by some as a bondage, there is a good deal over and above which is really and truly a part of medical education, and which a student can only do effectually for himself. It was impossible, however one might try it, altogether to sterilise the human mind. The mind of man, from babyhood upwards, presents a fruitful soil on which one may grow almost anything, provided only that the thing in question is alive, or has the potency of life in it. The true distinction between education, properly so called, and what is termed mere erudition, or cramming, is that the latter consists of putting into the mind lifeless or comparatively inert matter, not necessarily useless, inasmuch as it may make a good manure, but not seminal, and therefore not capable of growth; while the former consists in a process of inoculation or insemination of the mind with principles which, being alive and fitted for growth, and finding there a fitting soil, inevitably tend to grow and develop into organisms. This being the essential nature of all education, that it is a growth as of a seed into a plant within the mind, there may be, nay, there must be, a bad education possible as well as a good. The principles of evil will grow in that fruitful soil of the human mind just as well as the principles of good, in some cases, perhaps, still more actively and irrepressibly. The one point in both instances which makes it an education is that it is a growth; that in the act of developing into an organism the seminal principle implanted or inoculated alters the very constitution of the mind itself as effectually as the yeast fungus changes the nature of a saccharine solution, or the septic organism disintegrates the nitrogenous elements in which it becomes developed. Continuing the analogy, Professor Gairdner stated that this education, or insemination, of the mind for good or for evil was, in reference to other minds, of the nature of a contagion or infection. A small, often an infinitesimal, inoculation of the results of education in one mind was sufficient so to influence another, or even a multitude of other minds, as to give rise to a similar growth in them to an extent practically limitless, so that a single truth in science, a single principle of working in an art, a thought that breathes, a word that burns, may spread its influence through a family, a school, a profession, or a nation, it may be, as surely as the torula cerevisiæ will multiply in any number of saccharine solutions, or as the germs of anthrax, or of small-pox, or of cholera will spread through any number of flocks and herds, or of human beings, all over the world, if only they find a fitting, and, still more, an unexhausted or virgin soil for their development. If one does not implant, or inoculate, the right kind of germs, or educational influences, in sufficient abundance, or if one does not place them in the necessary conditions for their growth, other influences will certainly occupy the field, and will grow there in spite of all efforts, till the mind becomes, like the world in the eyes of the Prince of Denmark—

> "An unweeded garden,
> That grows to seed: things rank, and gross in nature
> Possess it merely."

THE late Mr. Jonathan Barlow by his will directed that the residue of the pure personalty be handed over to the vestry of St. George's, Hanover-square, or the vestries of any of the adjoining parishes, at the discretion of his trustees, for the maintenance of public waterclosets and urinals and their proper inspection, so that the public may have free use from the public thoroughfare.

Reviews and Notices of Books.

On Sclerosis of the Spinal Cord. By JULIUS ALTHAUS, M.D., M.R.C.P. Pp. 385, with nine engravings. London: Longmans and Co. 1885.—The first 323 pages of this volume are chiefly occupied with the morbid anatomy, pathogenesis, etiology, symptoms, diagnosis, prognosis, and treatment of so-called tabes dorsalis. There can be but little question that "locomotor ataxy" deserves all the attention which it has received at Dr. Althaus' hands. The work is strongest on the clinical side; that department, in fact, in which the author has had the most experience. Chapter 6, on the symptoms of "tabes spinalis," is a very careful and accurate study of the disease. In the first or pre-ataxic stage of the malady the author makes twenty-one divisions, not to count the subdivisions. The process of division is not carried too far. A glance at the table of contents relating to symptomatology perhaps does more towards giving one an idea of the protean nature of the pre-ataxic stage of locomotor ataxy than any amount of continuous reading would do. The whole work is highly commendable. A characteristic feature is the introduction of a large number of clinical cases gathered from the author's wide experience. In the departments which are not devoted to the symptoms and treatment of the disease, Dr. Althaus presents his readers with the best results of other authors. Recent researches receive proper recognition in their appropriate places. This work cannot be reviewed in other than a favourable strain. In phraseology a few peculiarities may be found. We do not appreciate the phrase "reflectory rigidity of the pupil" as a descriptive one for the "Argyll-Robertson pupil." Dr. Althaus speaks favourably of the use of antisyphilitic treatment in the first stage of "tabes dorsalis." "As far as electricity is concerned, however, we must look to the constant current as our sheet-anchor in these cases. The constant current is not able to restore central nerve tubes which have been destroyed, but it has the tendency, by its catalytic and stimulating effects, to improve the nutrition of those which are beginning to be diseased, to strengthen the remainder, and also to some extent to call into play the law of substitution, thus causing healthy fibres in neighbouring strands to perform the work of others which have perished." It is perhaps too much to believe that the constant current exerts all the properties which are here attributed to it.

Transactions of the Academy of Medicine in Ireland. Vol. II. London: Baillière, Tindall, and Cox. 1884.—This second large volume is a very good continuation of the new series. Want of space forbids our giving it the full recognition it deserves. The subjects of which it treats are both numerous and varied. The articles in the Pathological Section are exceptionally good. Mr. Benson's investigations into the nature of jequirity inflammations constitute a new chapter in the progress of the pathology of inflammations caused by the drug. Dr. Nixon's papers on brachial monoplegia and reflex paralysis are of much interest and Mr. Story's articles on cases of disease of the nervous system must also be mentioned. Mr. Stokes' case of ossifying sarcoma of the skull is accompanied by an excellent illustration. Nine other illustrations give the volume an additional value.

The National Dispensatory. By ALFRED STILLÉ, M.D., LL.D., and JOHN M. MAISCH, Phar.D. Third Edition. London: J. and A. Churchill. 1884.—We have much pleasure in recording the appearance of a third edition of this excellent work of reference. It is an admirable abstract of all that relates to chemistry, pharmacy, materia medica, pharmacology, and therapeutics. It may be regarded as embodying the Pharmacopœias of the civilised nations of the world, all being brought up to date, with the exception of our own, which, from its antiquity, is useless for all practical purposes. The work, as a rule, has been very well done, a large number of extra-pharmacopœial remedies having been added to those mentioned in previous editions. The only fault to be found is with the paucity of references to pharmacological papers. It would be easy to give examples, but it will suffice to instance the subject of nitrite of sodium, the literature of which appears to have escaped the notice of the authors.

Life in the Soudan. By Dr. JOSIAH WILLIAMS, F.R.G.S. London: Remmington and Co. 1884.—At a time when our thoughts are largely concentrated on the Soudan, this work by Dr. Josiah Williams will prove acceptable to a considerable section of the reading public. Dr. Williams has travelled a good deal, and has seen something of military life as a surgeon in the Turkish Army. In 1881 he accompanied a party of gentlemen, who were visiting the Soudan for sporting purposes, and the book before us is his diary extending from the winter of 1881 to the spring of 1882. Dr. Williams is a lively writer, and has an eye for detail which is always pleasant in a book of travels. He gives the history of the journeyings of the caravan day by day from December to March, and a perusal of it affords a capital insight into the camp life of the sportsman, and some of the manners and customs of the tribes of Upper Egypt and on the borders of Abyssinia.

The Asclepiad. By Dr. B. W. RICHARDSON. London: Eade and Canlfield.—The October number of this quarterly maintains the high standard of its predecessors. An essay on the mental phenomena of typhoid fever is full of suggestions; the author believes that every definite physical disorder has associated with it its own equally well-defined mental phenomena. Typhus is marked by short, delirious, broken dreams; remittent fever by long, dolorous, painful dreams; scarlet fever by realistic dreams; and so forth. A spontaneous cure of extreme portal congestion by copious accidental hæmorrhage is a carefully related clinical study. A coloured plate of perfect definition accompanies the description of disease due to bichromate of potassa. "Schools of Physic, Past and Present," is a very readable article. The article on a "Great Medical Reformer" has already received notice at our hands.

Christmas and New Year Cards.—Messrs. HILDESHEIMER and FAULKNER have forwarded to us packets of their leading designs in Christmas cards for the present season; also specimens of illustrated books. Many of these works of art are very beautiful. Our space will not allow of an enumeration of the specimens which have most excited our admiration, but the cards as a whole are of such excellence that no surprise can be felt that the above-named firm were successful in securing the gold medal (highest award) at the late International Exhibition.

THE University of London Lodge of Freemasons No. 2033, held a meeting on Thursday last, under the presidency of Mr. F. A. Philbrick, B.A., Q.C., when the following resolution was moved by the chairman, seconded by Dr. Alfred Meadows, J.P., and unanimously carried: "That this Lodge desires to place on record the expression of its sincere regret at the decease of one of its first members, the late Bro. Havers, F.R.C.S.E., and to express its sense of the great loss which English Freemasonry has sustained by the removal of one of its most able and zealous supporters." At the close of the meeting Professor J. Curnow, M.D., called attention to the circumstances attending the sad death of the late Dr. Rabbeth, a distinguished graduate of the University, through his self-devotion in endeavouring to save the life of a child patient, and the members present made a substantial addition to the fund now being raised for the purpose of establishing in the University a gold medal in honour of his heroism, and to perpetuate his memory.

Abstracts
OF
INTRODUCTORY ADDRESSES
DELIVERED AT THE
DUBLIN HOSPITALS & MEDICAL SCHOOLS
AT THE
Opening of the Session 1884-85.

ROYAL COLLEGE OF SURGEONS MEDICAL SCHOOL.

MR. STACK pointed out the attractions that Dublin possessed, in a scenic point of view, over other centres of learning, but there were, however, more solid grounds for preference. First of all he would mention the admirable clinical training that was given, far superior in every way to that provided in some of the best London hospitals. The lecturer then enumerated the various branches of knowledge which the students on entering would have to take up—anatomy, physiology, chemistry, materia medica, toxicology, and mechanics—and having dwelt upon the amount of general knowledge that should be brought to the study of each of these subjects, he pointed out how essential a thorough grasp of them was to a comprehensive knowledge of the requirements of the profession. Mr. Stack next referred to the particular branch with which he was connected. A truer knowledge of dentistry, he said, was now being diffused; great progress had been made in it in the medical schools throughout the United Kingdom, and the Council of the Royal College of Surgeons of Ireland had introduced into their schools all the most recent appliances in connexion with this long-neglected study. With the aid of some diagrams he next explained the structure of the teeth, and the various methods that had been adopted for arresting their decay. The use of plates was being gradually superseded, but it was evident that for a long time yet they would have to be used. He remarked upon the advantage it was to a dentist to have a knowledge of chemistry; in fact, of all the branches he had already referred to as entering their curriculum. He concluded by exhorting the students to apply themselves to their studies in such a way that they should hereafter become a credit to their College and ornaments to the noble profession they were now entering.

ST. VINCENT'S HOSPITAL.

DR. QUINLAN, after some prefatory remarks, referred to the results of the recent Copenhagen Congress and to the scientific work done there. Speaking generally, it might be said that the Copenhagen meeting showed that the most wonderful progress had been made in the last seventeen years, during which the profession of the whole civilised world had worked as one harmonious body, and had met periodically for international discussion. No other human avocation or calling presented the spectacle of several thousand scientific investigators from every part of the globe meeting together for a week in some selected rendezvous, listening and discussing, generally through the medium of some artificially acquired language, and the flitting to their distant homes enlightened and improved. There they heard and saw those famous celebrities who would otherwise be to them simply names. To enter into details would be impossible, but he would single out the great discovery of M. Pasteur, who appeared to have found out a method of extinguishing hydrophobia. M. Pasteur succeeded in attenuating the hydrophobia poison, and inoculated dogs with this enfeebled virus. The animals sickened but got well, and having gone through this process were found to be protected against hydrophobia even more effectually than ordinarily inoculated human beings are against small-pox. The next most important address was that of Tommasi Crudeli, of Rome, upon malaria. The debate on pulmonary consumption and tubercle was a remarkable one, notwithstanding the absence of Prof. Koch, who was not there to defend his bacillus. It was enlivened by the declaration of Prof. Jaccoud of Paris, that the bacillus discovery was almost sterile for clinical purposes, nor will any practical physician deny this. The infective character of consumption was admitted, but while there is no doubt that in Southern Europe there is an actual danger, in our colder latitudes the occurrence is exceptional. He would earnestly recommend his young audience to cultivate such an acquaintance with French and German as would enable them to at least understand these languages when spoken or read. The next meeting would be held in New York in 1887, and the following one in 1890 and probably in Constantinople. There was great and noble work to be done, and let them hope that their great cosmopolitan profession would approach it with intelligence, patience, and energy; with no political, religious, or personal object to serve, but looking solely to the advancement of science and the benefit of their common humanity.

MATER MISERICORDIÆ HOSPITAL.

MR. M. A. BOYD, after recommending his hearers to seek to obtain degrees in arts as well as medical degrees, and expressing his opinion that the prospects of scientific education never looked brighter than they do to-day, said that our knowledge of therapeutic science, or the physiological action of medicines based on scientific experiment, was every day being added to, and the action of remedies both new and old more thoroughly understood, and our knowledge of them rendered more accurate. In this particular branch he would instance the use of a number of new antipyretics or remedies that abate undue heat of body by lowering arterial tension, and regulate the action of the heart and blood-vessels through the nerves that govern them. It was seventeen years since the revision of the Pharmacopœia, and since then a number of new drugs had been introduced. During this time operative surgery had been revolutionised by the antiseptic treatment of wounds; dermatology by the use of petroleum ointments, and therapeutics swelled by the introduction of many important drugs and definite chemical remedies. The student of to-day had not to cudgel his brains as to what was the direct specific for this disease or that; his more exact knowledge of disease as affecting different organs, and the pathological changes taking place therein, consequent on their alteration or arrest of function, enabled him now to meet disease with remedies whose physiological action was in direct antagonism to the morbid alterations he had to treat. In this he could not fail to observe how the knowledge of the physiology of drugs simplified his art, and brought medicine day by day nearer to the goal it must ultimately attain of being an exact science. What would be the surprise of a practitioner of the old therapeutic school if he could rise from his tomb and see his most cherished remedies, his Lares and Penates, shattered and broken, the iconoclasts rushing in on all sides and from every country to share in the work of demolition. Still more would he be astonished to see a joint or an abdominal cavity laid open fearlessly by the surgeon of to-day, under an antiseptic atmosphere, or a chest tapped by aspiration, and fluid that pressed injuriously upon the lungs or heart withdrawn, with none of the untoward results of a bygone surgical time, when such operations would be looked on as certain to lead to a fatal result. The lecturer concluded by urging on students the cultivation of the senses in the investigation of disease, as well as of a wholesome scepticism in the value of vaunted remedies; also of patient courtesy in meeting the whims and petulance of those who might come under their medical care.

MEATH HOSPITAL.

THE lecture introductory to the session was delivered on the 3rd inst. by Professor RAWDON MACNAMARA. Speaking of medical students in general he said that as a class they came to them for the first time free from restraint, fresh from school, young, full of animal spirits, and perfectly unaccustomed to the temptations of a city life. Rough, selfish, thoughtless, unsympathetic, they might appear to be on their first entrance within the wards. Yet after a time, let occasion arise, who so gentle, who so thoughtful, who so sympathetic, who so self-denying, who so tender hearted. What a wonderful transformation! a transformation only, as he believed, to be seen in their ranks, and only to be accounted for, reverentially let it be said, by the Divine afflatus breathed upon their class through the person of the patron of their order, St. Luke the Evangelist.

As to the manner in which they should approach the discharge of their duties, he might be permitted to say a word. The regulations of their several licensing boards left nothing for him to say as to their preparatory studies beyond this, that in the majority of instances such regulations look upon such studies as being final. A more unhappy result could not be well conceived. He could well conceive a test examination as to whether the young man was fit at all to commence medical study—this of an elementary character, necessarily so; but of a final character, no; and he could not too strongly express his view that the only true way to establish their profession on a solid basis was to require some such academic position as would be evinced by an equivalent at all events to a degree in Arts, as conditional to admission within their portals. It might be utopian to look forward to this outcome of medical legislation, but nevertheless it was that for which they should agitate in the true interests of their profession. It had been well asserted that the gateways of knowledge were five in number—"seeing, hearing, tasting, feeling, and smelling." In pursuit of the study of their profession each of those gateways must be successfully stormed if they would be successful practitioners. Individually each one or other of these might be misleading, collectively they were proof strong as Holy Writ. The lecturer proceeded to bring forward arguments in favour of vaccination, and expressed his belief in the germ theory, but would not advocate the use of the carbolic acid spray. He concluded as follows:—"My idea is that to constitute a perfect physician a rare combination is essential—wisdom and experience. A man might be very wise, yet, lacking experience, will be but a poor practitioner; in like manner he may have great experience, yet, wanting wisdom, he never will carve for himself a niche in the temple of science. Inseparable from wisdom is truth. Without truth all is vain in science; for in it lies the foundation of all science. The grand characteristic of truth is its capability of enduring the test of universal experience, and of coming unchanged out of every possible form of fair discussion. Experience and wisdom, walking hand in hand, alone can add to our stock of medical knowledge. Wisdom will suggest that which experience will test, and the outcome is knowledge. But, gentlemen, above all things and before all things, bear in mind that "the fear of God is the beginning of all wisdom."

THE INTERNATIONAL HEALTH EXHIBITION.

MISCELLANEOUS FOREIGN EXHIBITS.

AMONG the exhibits grouped near the French and German courts there were many objects that suggest wide and as yet undeveloped sources of food-supply. Not that all these exhibits were worthy of encouragement, indeed some of them should not have been admitted. For instance, we do not understand why the Danes should have devoted so much space to exhibiting false colouring material for cheese and butter, and we protest against the huge stand which, like an altar, was raised in honour of butterine. If butter cannot always be obtained there is an ample supply of oil, notably the pure olive oil exhibited close at hand by Signor Carlo Gassi. Of the Scandinavian exhibits, the Swedish arrack punch has found much favour, particularly when combined with pine-apple; while the very delicate hurtle-berry preserves (*lingon vaccinium vitis idæa*), gathered in the mountainous districts of Sweden, were found most useful in arctic expeditions as a preventive against scurvy.

In the Swiss section were shown Mauchain convertible tables from Geneva, ingeniously contrived to prevent stooping; Souchard's chocolate mixed with iron—an agreeable means of taking a nutritious sweetmeat and a tonic combined; Chevallier's flexible capsules, easily swallowed, though the size of a pigeon's egg; and Dennler's Alpine bitters and iron, familiar and welcome tonics to the mountaineer. Forming part, apparently, of the Swiss section, though in no way connected with it, was the exhibit of Madeira wines by Wm. Gibson, and which are known as Blandy's Madeira. Some of these wines, especially the rich old "Bual," may prove useful for therapeutic purposes. Claiming to be equally useful for invalids is the "selected grapes" champagne of Messrs. Dupuy et Fils, Epernay. This wine is remarkably dry and free from the unpleasant after-effects which too often are found in champagne. The Amontillado from Wilson and Parker's vineyards at Xerez, imported by Messrs. C. Buswell and Co., is also a notable wine for dryness and flavour. The American Sea Foam wafer biscuits will bring out the flavour of these wines, which, with this light support, will constitute a pleasant and safe stimulant. The importers of the biscuit just mentioned, Messrs. A. W. Latham and Co., were also exhibitors of some admirably preserved fruits from California, where orchards of European origin were planted many years ago by monks. In spite of the long journey they retain their original flavour, and will supply a wholesome winter dessert. But the pine-apples from Singapore are a still greater delicacy. Instead of being preserved in sugar, they float in the juice extracted from those fruit that was too ripe for exportation; their flavour is consequently greatly intensified. Californian honey may also be recommended for its purity and admirable condition of preservation.

One or two more foreign exhibits remain on our list meriting notice, though quite disconnected with each other. The first among these were the boots shown by M. Méliès, who seeks to combine elegance of appearance with regard for the anatomical requirements of the foot. While avoiding exaggeration in shape, we nevertheless have the low flat heel, the broad sole, and room enough for the spread of the toes. Studying closely nature, it will be observed that the sole of the foot is not flat, and that treading on a hard even surface forces the foot upwards against the boot. Therefore M. Méliès has indentations on the inner surface of the sole within the boot, so that the foot retains its natural contour, and thus a high degree of comfort is secured. Again, if the boot causes pain, we lean or walk on the side furthest from the sore point; and bootmakers generally enlarge the boot on the tender side. This, says M. Méliès, is a mistake; relief should be given on the opposite side. Due observance of these principles has won for this firm medals at all the Exhibitions and the highest consideration in the trade.

Close by the exhibits of Rimmel, "whose very name smells sweet," as the late Mr. Blanchard Jerrold once remarked in one of his essays on French life, and who has contrived to perfume even coal tar soap, we found a unique display of sponges. The Greek sponges imported by Messrs. Henry Marks and Sons have taken some twenty-five years to collect. The rarity of shape and the fineness of texture constitute in certain of these sponges virtues which connoisseurs estimate at fabulously high prices, and this is not perhaps surprising, as one of the sponges in question cost the lives of two men before it could be snatched from its bed deep in the sea. When the Emperor of Germany was shot, his physicians sent all over Europe for some specially fine, cup-shaped sponges to dress his wounds, and only found what they desired among the rare collection of this firm. The bleaching of the sponge is a rather elaborate process. After immersion in muriatic acid, the sponge is soaked in a solution of permanganate of potash till it becomes almost black; but after this lime-water gives it the bright-yellow colour now in vogue. It will be seen that the process must remove all impurities.

WASHINGTON NAVAL MUSEUM OF HYGIENE.—During the past two years a museum of hygiene, organised under the Bureau of Medicine and Surgery of the Navy Department of the United States, has been in course of formation. The collection, which is extremely interesting and valuable, is in charge of Dr. J. M. Browne, Medical Director of the United States Navy. The library of the museum contains 7150 books, and also plans and drawings illustrating house and hospital construction, photographs of food and medicinal plants, and diagrams showing movements of disease. Attached to the museum is an experimental laboratory, equipped with the best apparatus for chemical, microscopical, physical, and physiological investigation, in which three hundred examinations have been made during the past year. The Bureau of Medicine and Surgery has ordered the purchase of several exhibits from the International Health Exhibition, London, among which are Mr. Francis Galton's apparatus for anthropometrical examinations, and Mr. Minnaert-Depunt's display of *sabots*.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 22, 1884.

THERE can be no greater mistake than to treat lightly the complaints of English students of medicine in regard to the hardship of compelling them to go out of their own division of the kingdom for degrees, medical or other. The desire to possess a medical degree may be wise or not. We cannot stop to argue that point here. Suffice it to say that the desire exists, and is becoming felt year by year by an increasing number of men, and that there is nothing in medical graduation but what is creditable to the individual and for the public good. So long as the terms of graduation are honourable, and the universities granting degrees are ready to give satisfactory public guarantees of their work, so long, it appears to us, should students be encouraged to graduate. At the present time in England, as compared with Scotland and Ireland, medical graduation is cruelly discouraged. The universities of Scotland, on the other hand, are said to make medical graduation too easy. Those who say so, including the great majority of London teachers of medicine, aver that graduation in Scotland is not more difficult, and does not imply the expenditure of more labour or money, than passing the two London Colleges. Professor TURNER, speaking before the Select Committee of the House of Commons, gave a very strong answer, at least so far as the University of Edinburgh is concerned, to those who so lightly disparage the present system of Scotch medical graduation. He gave particulars of the enormous sums of money that have been spent in university buildings, including chemical and physiological laboratories, of the curriculum of study, and of the nature of the examinations for medical degrees, which should at least be pondered by those who despise Scottish degrees. Professor TURNER'S evidence was the more effective on this point as he spoke from experience as an examiner in the University of London as well as from the point of view of a prosperous Scotch professor. We must leave the advocates of Scotch graduation and its assailants to fight this out, freely admitting that the Scotch universities in their recent action, under the fatal and misleading guidance of Sir LYON PLAYFAIR, have given too much reason to their enemies to say that they are afraid of public tests, and jealous for the pecuniary rather than the scientific and intellectual interests of their institutions. Whatever the truth on this subject, there can be no doubt of the fact that London, with its unrivalled field for clinical study, is placed at a great disadvantage in having no teaching university from which a degree on honourable terms can be obtained by English students, and that, in these circumstances, nothing remains but for them to go elsewhere. The act that this metropolis, with its four millions of inhabitants, the centre of commerce, and the home of the principal learned and scientific Societies of Britain, should not have a teaching university, is one that only needs to be stated to excite dissatisfaction and almost indignation. The like of it cannot be found in any other country known to civilisation. It is so unreasonable and anomalous that it cannot be suffered to continue. Now, when Liverpool, Manchester, and Newcastle are to be brought under academic influence, London must assert her transcendent claim to consideration. We speak from a medical standpoint with extreme responsibility. The study of medicine in this metropolis is conducted in a way that commands the respect of every foreign nation. There is no field comparable with that of London for the purposes of clinical and scientific medicine. And from this field our students are driven, often just at the very time when they most need its advantages. Their reason for going is the desire to graduate in universities where residence is a condition of graduation, and where, too, they imagine that they will best secure their ends by studying the crotchets of the professors by whom they have finally and chiefly, though not exclusively, to be examined. This is unfair to medical students, and it is grossly unfair to medical teachers, who are thus often deprived of the legitimate credit of conducting the final steps in the education and graduation of their best students. It is also unfair to the cause of medicine itself, in London, the pursuit of which would be stimulated by the creation of a teaching university controlling general and medical education, and giving proper form to the process of medical graduation. It is gratifying to find that these views, already foreshadowed in this journal, are taking practical shape and commending themselves to men of different character and calling, men so various and yet so influential as Lord REAY, Lord Justice BOWEN, Mr. FREDERICK POLLOCK, Mr. BRYCE, M.P., Sir FARRER HERSCHELL, Professor HUXLEY, Sir JAMES PAGET, Sir JOSEPH LISTER, Sir GEORGE YOUNG, Mr. ERICHSEN, Dr. PYE SMITH, Mr. MARSHALL, Dr. ORD, Professor CROOM ROBERTSON, Dr. WAGE, and others. In this list of names the existing University of London is powerfully represented. That university, to hear some speak, would seem to be hopelessly crystallised into its present form as a mere forcing and examining board, whose regulations are like the laws of the Medes and Persians, unalterable. The absolute self-satisfaction attributed to the London University is not shared by many of its most honoured medical graduates. At any rate, it is not the note of a wise and living institution capable of doing the most good and leading the academic life of London in present circumstances. We are unwilling to believe that the university is so hopelessly conceited as not to be able to meet the demand now pressed from so many sides, and even from its own graduates; it is still less credible that the medical schools and corporations of London will throw difficulties in the way of establishing a great teaching university in the metropolis. Under a well-appointed scheme, most, if not all, of these institutions would acquire new and higher functions, without being deprived of those they already possess.

A PATHOLOGICAL and clinical study which promises to exercise the best minds of the present generation for some years to come is the question of the nature of CHARCOT'S joint disease. It is mainly a question whether or not the morbid process implied by this name ought or ought not to be dethroned from the peculiar position which it at present

Digitized by Google

occupies and into which it was placed by the researches of the renowned physician whose name the disease bears. It was in the year 1868 that the arthritic disease first received public consideration. CHARCOT then published a case of joint disease alone, and it remained a question whether it was truly arthritic or merely osteoid in anatomical basis. Five years later descriptions of specimens were recorded where spontaneous fractures of the shaft of the long bones and joint mischief coexisted. By a careful study of the microscopical appearances LIOUVILLE arrived at the conclusion that the fractures and the arthritic changes were primarily due to a rarefying disease of the osseous tissues. It cannot but lead to the elucidation of truth if in the present state of affairs an attitude of scientific scepticism be adopted by all who take part in the consideration of arthritic and osseous changes occurring in patients the subject of tabes dorsalis. Whether the joint disease be merely the result of an injury in an individual who is the subject of tabes dorsalis; whether the arthritic mischief be an example of rheumatoid arthritis modified by the special conditions of the sufferer; whether the arthritic disorder be an idiopathic inflammatory process associated as a coincidence with tabes dorsalis; or whether the joint disease be as special as the name which it at present enjoys indicates—are questions which may be usefully discussed. We confess that the arguments which were urged by Dr. BUZZARD in favour of CHARCOT'S original contention seem very cogent and powerful. It is nothing to the point to argue that some physicians—e.g., Dr. MOXON—have never met with an instance of the disease in a certain number of cases of tabes dorsalis. It is to the point to assert that cases of joint mischief have occurred in which some of the joints showed changes unmistakably identified as those of rheumatic arthritis, whilst another articulation presented alterations which were equally certain, like those conditions met with in CHARCOT'S joint disease. We say it is to the point, though the interpretation put upon the facts by Dr. HALE WHITE and others may not have been arrived at by a conclusive form of argument. We cannot deny the truth of the axiom that many morbid processes may lead up to the same anatomical alterations; and dead-house experience is unable to settle the case in point. In the discussion at the Clinical Society, Dr. BUZZARD was at most pains to prove that the joint disease was not the same as rheumatoid arthritis. The rarefaction of bone with associated widening of the Haversian canals, which become largely occupied by fatty material, may be taken as the typical change which occurs in CHARCOT'S joint disease. Dr. BUZZARD suggested that some method of determining the specific gravity of the bones entering into the formation of the diseased joint might prove of value to surgeons, as helping to arrive at a diagnosis of the nature of the arthritic disease.

Suppose it were granted that CHARCOT'S disease is a specific malady and due to damage of the nervous tissues, it is by no means settled where the lesion is located. CHARCOT himself thought that the seat of the lesion was in the nerve cells of the anterior cornua, and in some cases which had lasted a long time CHARCOT and JOFFROY found that the anterior horns of grey matter were remarkably atrophied, and a considerable number of the large ganglion cells, especially those of the postero-lateral group, were atrophied or completely destroyed. In unilateral articular affections these changes were limited to the corresponding side of the spinal cord; and when the shoulder-joint was alone affected, the disease was detected only in the cervical region, and similarly, when the knee was involved, the alterations were discovered only in the lumbar region. But TALAMON failed to discover the change in recent cases of CHARCOT'S disease.

Some authors have believed that rheumatoid arthritis owned a neural cause, and certainly the muscular atrophy which attends many of these cases is very remarkable. Nevertheless, we must not forget that changes may occur secondarily in the nervous tissues as the result of damage to disease of joint, bone, and muscle. The changes which have been met with in the cord in cases of pseudo-hypertrophic paralysis have been regarded by GOWERS and others as of a secondary nature. BUZZARD has framed a hypothesis on the frequent association of gastric crises with arthropathies to the effect that some centre exists about the vagus nucleus which controls the nutrition of the osseous system. PITRÈS and VAILLARD have discovered inflammatory alterations in the peripheral nerves in cases of trophoneurosis associated with locomotor ataxy. PIERRET has recorded cases of locomotor ataxy in which no discoverable change existed in the spinal cord. It will thus be seen that many hypotheses may be framed to explain the occurrence of the joint disease which is believed to be special to tabes dorsalis.

AS will be seen from a report which appears in another column, the Council of the Royal College of Surgeons of England held an extraordinary meeting on Wednesday to consider two very important matters—namely, first, Mr. CHRISTOPHER HEATH'S motion on the mode of electing the President and Vice-presidents; and second, the Recommendations of the Association of Fellows. Mr. HEATH'S motion, which was divided into two parts, did not aim at any more than a slight change of custom. Heretofore it has been the custom of the Council to elect annually the senior vice-president to the office of President. The two vice-presidents in their turn are chosen by rotation from among the senior members of the Council, and each usually holds office for two consecutive years. The first part of Mr. HEATH'S motion sought to make the office of Vice-president tenable for one year only. The second part of the motion did not involve any alteration in principle, inasmuch as there is nothing to prevent the Council if it choose to re-elect the same member of Council to the office of President for any number of times. Hitherto the Council has not chosen to exercise the power, but has followed the easy, convenient, and amiable practice of making the election by rotation. Even if the second part of the motion had been adopted, there would have been no guarantee that the custom hitherto followed would be departed from. On the other hand, the amendment proposed by Mr. CADGE involved an important and acceptable change of principle. It recommended that the President of the College should be elected by the Fellows. Apart from the reasonableness of this proposal, it has the further advantage of coinciding with one of the Recommendations of the Association of Fellows, and we are willing to believe that this was the only reason against its immediate adoption by the Council. It was wisely referred to the committee on Charters and Bye-laws,

Digitized by Google

to which all the Recommendations of the Association of Fellows were subsequently referred.

We shall await with interest the report of this committee on the Recommendations of the Fellows. It is scarcely credible that the Committee of the Council will again be guilty of the unwisdom of deliberately ignoring the wishes of the most active, and, we believe, the most intelligent section of the Fellows. The Recommendations of the Association may require some modification to make them workable, but it cannot be questioned that as regards their general scope and character they are calculated to promote the efficiency and the welfare of the College. There is nothing revolutionary or chimerical or Quixotic in hem. They impose no hardships on the Council, and certainly imply no degradation. They simply make the proper and reasonable demand that the eighteen thousand Fellows and Members shall share with the twenty-four Members of the Council the responsibility of managing the largest medical corporation in the world. If the Council has the political sagacity to allow the claims of the Fellows and Members, the College must acquire increased influence, importance, and stability.

There is little in the Recommendations of the Association of Fellows that has not at some time and in some form been proposed and recommended by some of the most enlightened men who have sat in the Council. Their fulfilment cannot be longer postponed. Time, circumstance, and temper are all alike propitious to a prompt, liberal, and efficient settlement.

THE Committee of Comparative Pathology, which was formed by the Pathological Society at the instigation of Mr. HUTCHINSON when President, is fortunate in having amongst its members so industrious a worker as Mr. J. B. SUTTON. The contributions which that gentleman is making to our knowledge of disease in animals show how wide is the field open for inquiry, and also throw much light upon the nature of morbid changes in man. The communication made by him to the Society at its last meeting covered a quite novel ground, for hitherto little or no attention has been paid to uterine and ovarian disease except among the domestic animals. Mr. SUTTON'S research went much beyond this, for he has examined amphibia and birds as well as mammals, and has thereby succeeded in tracing the origin of such aberrant formations as parovarian cysts low down in the scale of animal life. He demonstrated in frogs and toads the frequent occurrence of cysts connected with the Müllerian duct of the male animal—structures mostly overlooked,—and proved the homology of these cysts with like formations connected with the rudimentary right oviduct of birds and the parovarium of the human female. From this arose the generalisation of the tendency to cystic disease in structures that persist as rudiments of fœtal formations. The occurrence of such disease in birds led to an incidental reference to the connexion in birds between the assumption of male plumage by the female and the derangement of the generative organs. Amongst many points of interest were the descriptions of uterine flexions in monkeys and deer, and the explanation given of the occurrence of these deformities in some cases. The Society appreciated the shrewd remark that such flexions produced no symptoms "probably because the animals were not cognisant of their possession of a uterus." The not infrequent occurrence of fatal peritonitis in the kangaroo received an explanation from the greater liability in that animal to a form of metritis from retained secretions owing to the peculiar structure of the uterine cavity. The frequent occurrence of cystic disease of the ovary in the mare, and its relation to the rich vascular supply, was another of the matters which has been investigated with so much care, and with remarkable assiduity, by Mr. SUTTON. We regard the prosecution of this line of research as being one of the most important that the Society could well undertake. Human anatomy and morphology depend largely for their true interpretation upon the facts of comparative anatomy; and what is true of normal structure is doubtless also true of morbid, so that we may hope to learn very much in the future as to the real nature of disease in man by the scientific prosecution of comparative pathology.

Annotations.

"Ne quid nimis."

THE HEALTH OF LONDON.

THE health of London, judged by its mortality statistics, has been unprecedentedly satisfactory during the past seven weeks. It appears from the Registrar-General's weekly returns that the annual death-rate from all causes in Registration London, with its estimated population of more than 4,000,000 of persons, did not exceed 18·9 per 1000 during the seven weeks ending November 15th. The nearest approach to so low a death-rate in the corresponding period of recent years was last year, when the rate was 19·3. With regard to the mendacious report of a portion of the Paris press that cholera is epidemic in London, it may be noted that the only death during these seven weeks from disease of a choleraic character was one of an infant, aged one year, certified to have died from "choleraic diarrhœa." The total deaths in London during this period of seven weeks from all forms of diarrhœal disease were 265, which were but 15 above the average number from these causes in the corresponding period of the ten years 1874–83, after correction for increase of population. The deaths from all the principal zymotic diseases in London since the beginning of October have been, with the exception of small-pox, considerably below the average. The recrudescence of small-pox prevalence is, in fact, the only unsatisfactory feature of the recent mortality statistics in London.

PHYSICAL SCIENCE IN EDUCATION.

THE education of the mind is guided by the use of letters or words. Words are the clothing of thought, and thought, at least in its primary and purest forms, is born and bred of association with nature. Led by these considerations, one can trace the pedigree of mental training and of language to its origin as a branch of the study of physical science. Even a formed language is flexible or apt in expression in proportion to the fidelity with which it follows its first aim, which is to give true and clear voice to intellectual ideas founded on observation. Most of us will, therefore, be prepared to agree with the teaching of a pamphlet by Mr. George Greswell of Rondebosch College, South Africa, that in all school programmes the cultivation of natural science should hold a place in keeping with its relation to other studies. There can be no accurate conception of the force of words in common use even, unless the process of selection which has

Digitized by Google

been gone through in their formation—the results of careful observation of nature, its forms, their relation and analogies, out of which all speech has grown—be understood. The study of language thus carefully conducted, on the other hand, repays the learner with facility, vigour, and correctness of speech which could not otherwise be attained. The pupil may be very early initiated in the habit of observation and in the elements of natural sciences, and this need not interfere with his progress in the mastery of studies of a less immediately comprehensible kind, such as dead or foreign tongues, which have their own advantages. The truly rational understanding of even these is not lost sight of, because it is necessarily postponed to a comparatively late period of the educational course.

OVER-PRESSURE.

ON mature reflection public opinion is coming round to the conviction that Dr. Crichton Browne was right and that his traducers were wrong. We are the more assured of this, because knowing people and influential people in places of prominence and trust are striving to "burk" evidence in support of Dr. Crichton Browne, while they are apparently anxious to give all the publicity in their power to the most pitiful pleadings against him, and in destruction of the case he has set up, and, as we think, conclusively proved. It is always an excellent sign when the opposition take to suppressing evidence. *The Times* is just now doing this with great energy, and we hail the fact as a token of conscious weakness on the part of the side the leading journal has taken in this controversy. Meanwhile the oracles of skilled opinion outside the purely official circle are, with one accord, declaring in favour of Dr. Crichton Browne, and endorsing his statements. We fail to see how there can possibly be two opinions on the subject. The facts are so very clear. Without laying any particular stress on individual "cases" of injury to brain or life from over-pressure, we find more than enough evidence to place beyond the range of doubts and questionings the fact that the "code" and the "cramming" in use at the schools of compulsory national education are weapons of injury which should be taken out of the hands of officials who have shown themselves careless or incompetent in the use of them. There must be an inquiry, and it is well that there are indications of an intelligent, if not altogether willing, submission to the force of circumstances on the part of the School Board. It is to be regretted that similar sagacity—the instinct of self-protection—has not yet dawned on the consciousness of the Council of Education.

RAPID RECOVERY AFTER WOUND OF STOMACH AND PROTRUSION OF VISCERA.

A REMARKABLE case of recovery, after severe abdominal injury, is reported in the *Gazzetta degli Ospitali* (12th inst.) by Dr. Iginio Tansini. P. G——, aged forty-six, a peasant of Lodi, was admitted into the local hospital on the 10th of Aug. in a state of drunkenness, with an extensive wound in the left hypochondriac region. Through it protruded the stomach, the transverse colon, and a large part of the great omentum. On the anterior surface of the stomach was a wound an inch and a quarter long, through which the lining mucous membrane bulged, so as to fill it. That wound was closed with two fine catgut sutures. After cleaning the displaced viscera with cotton pledgets dipped in a two and a half per cent. solution of carbolic acid, reduction was attempted, but the tightness of the edges prevented it. As the wound reached upwards to the costal margin, it was extended an inch downwards, and the viscera replaced. The parietal wound was then found to measure three and a half inches. A considerable amount of blood having accumulated in the abdominal cavity, the toilette of the peritoneum was very carefully performed, with carbolised gauze soaked in warm carbolised water. The first pledgets brought away blood; and others were introduced amongst the coils of intestine, and into the pelvis, until they came away quite clean. After inserting a thick drainage-tube into the lower angle of the wound, this was closed with four deep and four superficial sutures of carbolised silk; a broad antiseptic dressing followed. Progress was uninterrupted; no fever supervened. In the first three days much bloody fluid was carried off by the drainage-tube, which was gradually shortened and definitely removed the eighth day. On September 5th, the twenty-sixth day after admission, the patient left the hospital perfectly cured.

DR. TOMMASI CRUDELI AND SOIL RECLAMATION.

PROJECTED by Caius Julius, but first set on foot by Claudius Cæsar, the desiccation of the Lake of Fucino has for centuries been at once a necessary and a difficult undertaking. The basin has no natural outlet sufficient for the surplus waters which in the rainy season and on the melting of snow descend from the mountain sides to overflow its margin and do infinite damage to the neighbourhood. Deputation after deputation from the lacustrine townships came up to Rome imploring the Senate, Republican or Imperial, to avert these devastating floods, but not until A.D. 52 did the Emperor Claudius, after eleven years' labour and the employment of 30,000 men, succeed in tapping the lake and draining it through an *emissarium* into the valley of the Liris. The ruins of this colossal work are still the admiration of the traveller, but no adequate attempt was made to restore it, much as the neighbourhood suffered in consequence, till within the last hundred years, when efforts were again and again renewed to reopen the choked-up *emissarium*. In 1852 a Swiss company obtained a concession of the lake, entitling them, if they tapped it, to all the land thus reclaimed; but the undertaking was too much for them, so their rights were purchased by Prince Torlonia, who at the cost of about £1,400,000, and with the aid of the Swiss engineer De Montricher (the constructor of the aqueduct of the Durance to Marseilles), made a more perfect *emissarium* and reduced the circumference of the lake to half an hour's walk. Even with the Prince's immense resources the work cost the lives of so many surveyors and *employés*—all of them victims to fever—that the country people used to say, "O Torlonia secca il fucino, o il fucino secca Torlonia" (Either Torlonia will dry up the fucino, or the fucino will dry up Torlonia). Some 15,000 hectares of the reclaimed land are now under cultivation and yield a good return to the farmer, but the place is haunted with malaria—a result which, according to Mr. Hare and other lovers of the picturesque, must deter the application of similar draining processes to the beautiful lakes of Thrasymene and Bolsena. With the view of studying the effects of the desiccation of the Lago di Fucino from a hygienic point of view, a commission, headed by Dr. Tommasi Crudeli and the Commendatore Simeoni, is now on the spot, and from the skill with which the first named pathologist has already conducted investigations of the same kind, the report embodying his conclusions is awaited with much interest.

THE CASE OF CASSAN v. FYFE.

OUR readers will remember that (THE LANCET, August 9th, 1884) we gave an outline of this case, in which the plaintiff complained of certain statements alleged to have been made by the defendant in reference to the treatment of a patient suffering from retention of urine and stricture. We need not here repeat the particulars. The case ended, as so many lawsuits are apt to do, somewhat tamely. The judge ruled that the statements attributed to

Digitized by Google

Dr. Fyfe had not been proved, except perhaps those made to the representatives of the committee of the club, which, being in the form of answers to questions, were to be regarded as "privileged." On these views of the law, the learned judge directed the jury to find for the defendant, but granted leave for an appeal. Mr. Cassan, having already suffered much loss of money by his attempts to get legal redress, is resolved not to spend any more over the costly and very uncertain remedy of law. Perhaps he is well advised; the more so, as the club whose medical man he is, and to which the patient whose case gave rise to this action belonged, have passed a resolution virtually confirming him in his appointment, and expressing the opinion that the charges against him were not substantiated. We congratulate Mr. Cassan on the continuance of the confidence of the club, to which we think he is well entitled, and he may be assured of the sympathy of the profession.

KUSSMAUL'S COMA.

AT a meeting of the Midland Medical Society, held at the Birmingham Medical Institute on Wednesday, Nov. 19th, Dr. Robert Saundby read a paper based on two cases of Kussmaul's coma, and pointed out that while this peculiar condition was originally described as occurring in diabetes, it is now known to exist in many other diseases, especially where there is profound blood disorder — e.g., pernicious anæmia, Bright's disease with anæmia, and in cachectic states. He discussed the etiology of the condition, rejecting as untenable the various views which ascribed the symptoms to anatomical changes, whether of the nature of coarse disease or in the shape of fat emboli, and maintained that it is most probably due to some at present undetermined form of toxæmia. With reference to this point he referred to the recent suggestion of Minkowski, that the symptoms are caused by the dealkalisation of the blood and tissues, from the constant over-production of an acid (β. oxybutyric acid) in the circulation. Dr. Saundby also pointed out the fallacies attending the ferric chloride test, as an indication of the presence of acetone, and showed a new and beautiful reaction discovered by Le Nobel, a rose-violet colour gradually developed on adding nitro-prusside of sodium and ammonia to a urine containing acetone.

THE "P. & O." COMPANY AND THEIR SURGEONS.

THE Peninsular and Oriental Steam Navigation Company on Nov. 1st issued a circular to the commanders of their ships containing certain regulations which, if persisted in, will in the long run inevitably lower the status of its medical staff. We have no fault to find with the first paragraph of the circular, which declares that "under no circumstances whatever is a surgeon to ask for a fee." It is reasonable that passengers should claim their right to professional services during the voyage for which they have contracted, so long as it does not entail degradation or injustice on the medical officers. But to the second and third paragraphs, which run as under, we enter our emphatic protest: "A passenger ..... is entitled to ask for and obtain a copy of any prescription for any medicine which the surgeon has administered to him." "It does happen that passengers in delicate health or subject to occasional attacks of illness will desire to obtain medicines which have been prescribed for them by previous medical advisers. It is our wish that every facility should be given by the surgeon to gratify this natural desire; and surgeons are requested to dispense any prescription which a passenger may ask them to make up, if they have the medicines required, so long as the prescription does not direct the employment of any powerful medicine in an unusual dose, and the passenger is not seriously ill." Conditions more derogatory than these it is difficult to conceive. Is it the wish of the company to treat a number of legally qualified members of a learned profession as though they were dispensing chemists and errand-boys? do they consider it necessary for the success of a commercial enterprise that their superior officers should be made instruments to satisfy every passing whim or fanciful ailment of voyagers? Fortunately for those most concerned, the four corners of the above-mentioned circular are within the limits of their discretionary power, and it will be easy for them to evade the provisions of such ill-advised resolutions. At the same time it is practically certain that friction will arise between the directors and passengers on the one hand and the doctors on the other; and there can be no question as to who will be the greater losers in the long run. We sincerely trust that the company will at once recognise their mistake and take steps for removing a certain cause of peril to their undertaking.

THE MICROCOCCUS OF GONORRHŒA.

THAT gonorrhœal pus contains numerous micrococci, and that inoculation of the healthy urethra with these organisms can excite a specific urethritis, are statements accepted by many since the researches of Neisser, Bockhart, and others. But according to Dr. Sternberg, of the United States army, whose bacteriological work is so well known, the evidence in support of the specific character of the "gonococcus" is inconclusive. Writing recently upon the subject, to which he has before given attention, he declares that morphologically the micrococci of gonorrhœal pus are not distinctive, but he rightly assumes that this does not imply that they have no specific qualities. One cannot but be reminded of the cholera bacillus in reading the following sentence of Dr. Sternberg's. He says that he "has repeatedly insisted upon the fact that these lowly plants often cannot be distinguished one from another by their form alone, and that specific differences may exist, as shown by a constant difference in colour, as in the chromogenes, or in physiological reaction, as in the case of pathogenic micrococci, when the most skilful microscopist can distinguish no difference in form, dimensions, or mode of grouping which would serve to distinguish one species from the other." The constancy with which micrococci are found in gonorrhœal pus suggests a relation between them and the infective virulence of the disease; but hitherto neither Dr. Sternberg nor his associates have succeeded in exciting gonorrhœa in healthy persons by inoculation of the urethra with cultures of these micrococci, which he is inclined to believe are usually harmless, but that they may acquire specific pathogenic properties under special conditions; a view, he thinks, in harmony with the successful inoculation obtained by Bockhart from cultures of the *fourth* generation, whereas his own experiments showed that inoculation of the tenth or twentieth culture is harmless. He has, however, repeated the experiment, with the ninth and eleventh cultures derived from gonorrhœal pus. The method employed was to introduce into the meatus a pledget of cotton saturated with the fluid culture, and to retain it there for two hours. The subjects of this experiment were the author, Dr. Keirle, and Mr. Wegefarth of Baltimore, and in each instance (repeated in the author's case) the result was negative. But Dr. Sternberg points out that there are always to be found at the urethral orifice, and other exposed mucous surfaces, bacterial organisms and micrococci, which are "morphologically identical" with Neisser's "gonococcus," the micrococci being far less numerous than the bacteria. "It would be well," he adds, "for every surgeon to make this demonstration for himself"; as it may well be that these organisms are septic, and liable to be introduced into the bladder by catheterism or into the wound produced by forcible dilatation of a stricture.

SUMMER DIARRHŒA IN 1884.

SUMMER diarrhœa, mainly infantile, was nearly twice as fatal in England during the three months ending September last as in the corresponding period either of 1882 or 1883. The annual death-rate from this cause last summer in England and Wales was 2·7 per 1000. In the twenty-eight largest towns it was 3·9, in fifty other great towns it was 3·2, and in the rest of England and Wales it was 2·0. It may be pointed out that the excess of mortality from this cause last quarter, compared with that which prevailed in the summers of 1882 and 1883, was greater in the small towns and rural districts than in the seventy-eight large towns. In the twenty-eight largest towns the diarrhœa rate ranged from 1·6 and 1·7 in Halifax and Huddersfield, to 6·2 in Norwich, 6·5 in Nottingham, 8·3 in Preston, and 9·1 in Leicester. Thus Leicester is again notorious for showing the greatest waste of infant life from diarrhœa last summer. Infant mortality from all causes in that town last quarter was equal to 424 per 1000, whereas the mean proportion in the twenty-eight towns did not exceed 242, the lowest rates being 161 in Bristol, 184 in Huddersfield, and 185 in Plymouth. In the fifty smaller towns the range of diarrhœal mortality was fully as wide. The rate from this disease was but 0·6 in Bath and 0·8 both in Swansea and Merthyr Tydfil, while it ranged upwards to 5·7 in Stockport, 5·8 in St. Helen's, 7·0 in Ipswich, and 8·4 in Northampton. A comparison with the rates prevailing in recent summer quarters shows still more remarkable and unaccountable variations. In Bath, Gloucester, and Merthyr Tydfil the death-rate from diarrhœa was actually lower last quarter than in the summer of 1883; whereas the rate was eight times higher in Northampton, and five times higher in Dover, Burton-on-Trent, and Ashton-under-Lyne. One of the other varying incidents of diarrhœa fatality in our large towns is the date of the greatest mortality in different towns. During last quarter, for instance, the highest death-rate from diarrhœa occurred in London in the week ending July 19th, in Leicester and Derby in the following week, in the greater number of towns in the week ending August 23rd, and in Halifax not until the second week of September. It may be hoped that the long expected report upon the causation of summer diarrhœa, which has been so long under investigation by the Local Government Board, may throw new light upon some of these now unaccountable variations in the incidence of this disease.

CONDUCTION OF PULMONARY PHYSICAL SIGNS.

A CLINICAL question which certainly deserves more attention than has hitherto fallen to its lot is the conduction of abnormal sounds produced in the lungs. The want of fuller study of this point has led, and no doubt will lead, to mistakes in topographical diagnosis; and the paper by Dr. Markham Skerritt, read at the last meeting of the Medical Society of London, will therefore be useful. The matter lies within a small compass, and ordinary care is generally sufficient to prevent mistakes. The abnormal sounds produced in a lung consolidated by pneumonia, or compressed by air or fluid, may be heard on the side of the chest opposite to that in which they originate. The same applies to physical signs of phthisis at one apex, where it not unfrequently happens that the altered quality of breathing and the râles may be distinctly heard at the other apex, which post-mortem examination reveals to be healthy. Other examples of this conduction of physical signs have been recorded, but the above-mentioned are the commonest forms. Attention to information derived from palpation, percussion, and auscultation of the vocal sounds should prevent gross error.

A WORD TO THE ENGLISH CHOLERA COMMISSION.

THE statement made by a Calcutta correspondent last week, to the effect that Drs. Klein and Gibbes were shortly about to return home after having "exploded" to their own satisfaction the views of Dr. Koch upon cholera, will be read with regret, unless they are able to produce before the world of pathological science results of a more positive character than we have yet heard of. If their instructions were limited to an inquiry into the alleged specificity of the comma-bacillus, there was no need for their being sent to India at all. Material in abundance has been unhappily too rich during the past few months much nearer home. But if, as we would fain believe, the English Commission were instructed to inquire fully into the whole subject of the origin and dissemination of cholera, to discover its real nature, and to adduce facts drawn from the largest possible area in support of the truth of their views, then we fail to see that these objects can have been attained in the comparatively brief period of their sojourn in Bombay. We are jealous of the honour of British science in this matter. If the inquiry is to issue merely in the contradiction of the bacillar doctrine, but little will have been gained, and something indeed lost to the credit of our country. In the absence of any official statements it is of course useless to argue on this point; and we would not do injustice to these gentlemen, whom we are sure will have done their work thoroughly and well so far as it may have gone. Yet we fear very much that, unless they can show that their observations have been as extensive and thorough as those of the German Commission, they will receive less attention than they deserve, and may even place a bar upon progress in the direction of cholera research.

"MORBID RELIGIOUS AFFECTION."

ATTENTION is again directed to this subject, and a protest by the vicar of St. Mary's, West Kensington, against the insidious introduction of the confessional under cover of "missions" is a timely act of watchmanlike vigilance. We reproduce from Mr. Macnaught's manifesto a passage he quotes from Bishop Wilberforce: "If sisterhoods cannot be maintained except upon a semi-Romanist scheme, with its *direction*, with its development of self-consciousness and morbid religious affection, with its exaltation of a contemplative life, its perpetual confession, and its un-English tone, I am perfectly convinced that we had better have no sisterhoods." The "development of self-consciousness and morbid religious affection" in the lives of Sisters and their proselytes is a very serious matter indeed. Looked at from the medico-psychological point, the mischief in progress among unmarried women of emotional temperament and unstable nervous centres is the cause of grave anxiety to physicians, and already they are recognising clear evidence of the propagation of morbid disturbance from nurse to patient in the hospitals. Proselytising in hospitals is by no means a process of sober conviction. What Bishop Wilberforce characterised in his letter as "the soft influence of women's souls"—if he had been a physiologist he would have said "nervous systems,"—and against which he warned his clergy, is exerting a most injurious influence on brains which are constitutionally disposed to the irregular distribution and capricious discharges of nervous force. "Morbid religious feeling" is a distinct malady. It begins either with intense emotion, rising to ecstacy, as under the excitation of the nerve centres through the ear or the eye by music or pageantry, or it may be induced by that morbid, or even vicious, mental contemplation into which the minds of women, either very young or about the age of forty, are prone to fall while gazing at the crucifix. Parents and clergymen

Digitized by Google

who have a care for the moral purity of the women under their protection should interdict the use of the crucifix peremptorily and universally. It is necessary to speak plainly on this subject, and we cannot hesitate, in the interests of mental health, to ask the heads of families and all who have influence with the female part of the community to enter earnestly into its consideration. We write thus with a feeling of responsibility and under the pressure of strong conviction.

MARKETS OVER SEWER GRATINGS.

WHAT with being compelled to breathe and gasp with his head pressed down over the open mouth of a pipe communicating directly with the sewers while he is having his head shampooed, and being in divers other ways deliberately and, as it would seem, carefully poisoned with deleterious matter from the system of closed drains of which the sanitary engineers are so proud, it would appear to be needless to feed the British householder, his wife and children and servants, on vegetables elaborately fumigated with sewer gas. This superfluous attention is, however, bestowed on the propagation of disease and bad health. As Mr. Bolton King, honorary secretary of the Whitechapel Sanitary Aid Committee, points out, "Trucks of fruit and vegetables may be often seen standing directly over these (street level) ventilators, the foul air from the sewers rising freely to contaminate food which may perhaps be served up on a West-end dinner-table." The possible destination being a *West-end* dinner-table of course makes the matter more interesting. Lives are, as we all know, much more valuable to their possessors in the West than in the East, and the only way to bring a question of reform home to anyone is to show that it affects his own personality.

ATMOSPHERIC DISSEMINATION OF SMALL-POX.

MR. POWER, in his report on the spread of small-pox in the vicinity of the Fulham Small-pox Hospital, points out that the atmospheric condition preceding the outbreak that he specially investigated was favourable for the accumulation and deposition of particulate matter in that locality. This condition he describes as damp, still, and foggy. This view is contrary to the generally received opinion, which is, if the poison is conveyed at all by air, it is carried by strong currents of wind. It is interesting, therefore, to find that Mr. Power's observations with regard to the meteorological condition most favourable to the spread of the small-pox poison has also been recorded by some of the older writers on this disease. The most remarkable instance is that mentioned by Dr. Waterhouse, Professor of Medicine at Harvard College, in which the small-pox attacked simultaneously ten persons working in the same yard at Charlestown, which yard was opposite two houses at Boston, on the other side of the river, at a distance of 1500 feet, in which were cases of small-pox. The day on which the infection took place was "one of those dull foggy days (such as commonly produce a dark day in London) when there was scarcely wind enough to blow the smoke from the tops of the chimneys; yet what wind was stirring wafted it across the river to Charlestown." Another instance, too, is recorded in which "the atmosphere was for many days loaded with aqueous vapours," there being little or no wind; yet, in spite of the prevention by a military guard of all possible communication between the small-pox hospital and the neighbourhood, the disease was conveyed a distance of "several hundred roods" from the hospital. In this case the disease must either have been conveyed through the air or by the visiting physician; yet this official before entering the building covered his head with a cap and his body with a linen gown, reaching from his neck to his ankles; he even changed his shoes; whilst on leaving he was thoroughly fumigated, &c. The question raised by Mr. Power's report as to the possibility of the aerial dissemination of small-pox to a distance considerably further than has hitherto been supposed possible, is of great importance to the community; and with a view to the possible risk thus run, we think more attention ought to be paid to methods of disinfection, which would ensure the absolute destruction of particulate matter rather than the continuance of turning the infected air of these hospitals into the general atmosphere, under the idea that dilution is sufficient to render the poison innocuous.

THEATRES.

SIR WILLIAM HARCOURT is satisfied; what more can reasonably be asked? There are theatres in London which might be burned down in about twenty minutes—so far as the auditorium is concerned—and which have not sufficiently capacious or easily accessible ways of egress. These are facts within the knowledge of everybody except the Home Secretary and the Lord Chamberlain, and other officials; but facts are not simply stubborn, they are tiresome, unpleasant things, and it is discreet sometimes to ignore them. We do not urge further measures in the matter of legislation. By all means let matters go on as they are for awhile. There will be a great catastrophe in London by-and-by, and then it will be time to adopt effective means of safety. For the moment the subject had better drop. Members of the House of Commons should spare the Secretary of State further trouble in the business. Let the Home Office rest. There will be plenty for that department to do when the holocaust begins. Some day when there are eight thousand persons assembled in Covent-garden Theatre, and a fire, with the regulation panic, *happens*, it will be a consolation to know that the particular theatre in question does not open its doors under the annual licence of the Lord Chamberlain, but under a patent of Charles II. This will probably be a sufficient answer to any allegation of neglect. For ourselves, we think it will be quite as good as the plea that the Lord Chamberlain has done and is doing all he can with the inadequate staff of executive officers under his control. The proposal to place the Lord Chamberlain's office on a footing of efficiency, or else to abolish it altogether, is one of those schemes that must needs originate below the gangway, and therefore could not for a single instant be entertained by any Government possessing an atom of self-respect.

AN ILL-ADVISED PROSECUTION.

A CORRESPONDENT writes:—Dr. Whamond of Jarrow, a practitioner of standing and repute, had this week to undergo the annoyance of appearing at the local police-court to answer a summons of the Corporation for having, under the new Improvement Act, neglected to send in to the local sanitary authority a certificate stating the nature of a disease from which a patient of his was suffering. Dr. Whamond, it was admitted, had duly sent in a certificate which described the disease as "infectious," but with a mark of interrogation after the word infectious, signifying that it was of doubtful nature; the prosecution, however, maintained that he ought to have written the exact name of the disease. Evidence was given by the medical officers of health of Jarrow and a neighbouring borough to show that the case was one of typhoid fever; but in cross-examination both witnesses admitted that it was sometimes extremely difficult to distinguish between typhoid fever and other diseases. After a long hearing, the magistrates dismissed the case on the ground "that the evidence did not show that Dr. Whamond had wilfully disregarded the Act."

Digitized by Google

It is quite evident that Dr. Whamond followed the spirit, if not the letter, of the law, and that his certificate was a truthful one, and possibly said as much as he was justified in saying of the case at the time he issued it. Every practitioner knows that even a very few hours may clear up much that is obscure as to the nature of a case of continued fever. Therefore there can be but little doubt that the Jarrow Corporation was ill-advised in setting the machinery of the law in motion in Dr. Whamond's case, and that such prosecutions, even in the interests of sanitary progress, are to be much deprecated.

CLINICAL SOCIETY OF LONDON.

THE members of the Clinical Society had good reason to congratulate themselves on their last meeting. In point of numbers the occasion was almost unprecedented, a circumstance which cannot be accounted for by any very special reason. It is true that the number and interest of living specimens may have been an additional attraction. But it must be confessed that the meetings of the Society have of late been very well attended; so that we are inclined to believe that the plenitude of the recent gathering was but a further expression of the popularity of this important Society. Elsewhere will be found a full report of the proceedings, and an article bearing on the subject which perhaps most interested the members assembled. Dr. Stephen Mackenzie's paper was discussed with a fulness warranted by its value. A large specimen of spina bifida in a girl aged nineteen was exhibited by Mr. R. W. Parker for Dr. McLean of Portland.

CONGENITAL DISLOCATION OF THE HIP.

THE address at the opening meeting of the Surgical Section of the Academy of Medicine in Ireland, held last week, was delivered by Mr. Bennett, President of the Section. His discourse mainly turned on the subject of congenital dislocation of the hip-joint, and he referred to the various theories put forward to explain the cause of the deformity. He proved from the history of a specimen exhibited to the members that attributing the dislocation to a result of abnormal labour, as laid down in one of our most modern text-books, was erroneous. As regards treatment, he was of opinion that the only chance of doing any good was in the first few years after birth, as afterwards the changes which took place in the structures involved were such as to prevent a successful result from any operative measures that might be adopted.

SPIKED WIRE FENCES.

A CORRESPONDENT of *Land and Water* calls attention to the fact that farmers are putting up "miles of wire fencing, of which the top wire is studded with sharp spikes," and complains of the injury likely to result therefrom to man and beast. We can add to this testimony that in some cases not only the top but all the wires are spiked; surely a most discreditable and indefensible precaution. That people should be prevented from trespassing or punished for so doing is quite right and proper, but there can be no justification for part of that punishment taking the form of immediate personal injury. The possibility too, or rather probability, of the infliction of utterly wanton and needless injury and pain on such unconscious trespassers as dogs, sheep, horses, &c., is dreadful to contemplate. This barbed fencing is most aggressive, objectionable, and unnecessary; its aggressiveness is amply demonstrated by the fact of a lady finding it impossible to use a stile placed for foot passengers without getting her dress torn to rags. There is no good reason whatever why property should be enclosed by means of such a *chevaux de frise*. We trust, therefore, that owners of land will find means of replacing this dangerous fencing, or at all events of removing the unwarrantable spikes, which should be relegated to the limbo of spring guns and other man-traps.

THE PACINI MEMORIAL.

ON the 14th inst., in the Reale Arcispedale di Santa Maria Nuova, in Florence, a committee for the purpose of commemorating the life and labours of the late Dr. Filippo Pacini held its first meeting. The president was the Commendatore Professor Giorgio Pellizzari; the secretaries, Dr. Stacchini and Signor Squarcialupi; and the treasurer, Cavaliere Cosimo Franceschi, superintendent of the hospital. It was resolved to issue an appeal to the country; while a vote of thanks was conveyed to the Society of Hygiene for having initiated the project, and to his Excellency the Minister of Public Instruction for placing at the committee's disposal the sum of 500 lire (£20) *ad hoc*.

ACTION FOR MEDICAL ATTENDANCE.

IN the action Cass *v.* Fitzgerald, in which the plaintiff, a medical practitioner, sought to recover £96 for medicine and attendance upon a lady who, it was said, was at the time living with the defendant as his wife, the jury were unable to agree upon a verdict. They added, however, that they were quite unanimous that there was no imputation whatever upon the character of Mr. Cass.

THE ÆSCULAPIAN SOCIETY.

THIS North London Society has been in existence since 1880, and has now issued a small volume giving briefly an account of the proceedings of the monthly meetings. A glance through the pages of the volume shows the number and variety of subjects discussed, as well as the interest which the several papers evoked.

HAVING carefully looked through the drawings of the new additional buildings about to be erected at the St. Pancras Workhouse, the specifications to be observed in the construction of the floors, and the providing and fitting of the water-supply and fire extinguishing arrangements, Captain Shaw has issued a report, addressed to Mr. Bridgman, F.R.I.B.A., the architect, in which he states that he notes with pleasure the evident care and attention that have been bestowed upon the smallest details likely to assist in securing to the building an immunity from fire, or, in the event of fire occurring, preventing it extending to serious dimensions, together with the ample measures provided for its extinction.

WE are sorry to announce the death of Mr. Henry Renshaw, for so many years known as one of the leading medical publishers. Mr. Renshaw was one of the first to see the utility of publishing a condensed form of practical information for medical students and busy practitioners, in which enterprise he met a large success. Among the valuable series of manuals he published, perhaps Druitt's Surgery was the best known. Tanner's Practice of Medicine, Fox on Skin Disease, Clarke's Surgery, and Green's Pathology are only a few of the many popular works he brought out. Mr. Renshaw had been ailing for some months past, and finally succumbed to an attack of angina pectoris on Nov. 18th, in his seventy-ninth year.

THE Tasmanian Parliament has agreed to a motion declaring that some steps should be taken to provide for the proper education of midwives.

IN a paper recently read before the Paris Academy, M. A. Hureau de Villeneuve urged the importance of the use of distilled water for drinking purposes, and suggested that the price might be greatly reduced by obtaining it from steam engines at work in mills. He considers it is neither unpalatable nor difficult to digest; that it generally contains a sufficient quantity of air, and that the absence of calcareous salts is rather an advantage than a drawback.

ON Monday evening next, Sir Andrew Clark, Bart., M.D., will give a "Medical Talk" to young men in the Lecture Hall of the Young Men's Christian Association. The Earl of Aberdeen will take the chair at eight o'clock. The subject will be "Considerations respecting the Constitution of Man, and its Relation to Health, Knowledge, and Religion."

THE subject of Nephrectomy will be brought before the Royal Medical and Chirurgical Society on Tuesday next, Nov. 25th, by a paper from Mr. Henry Morris. An interesting discussion is expected to follow, in which, besides others, Sir Andrew Clark, Sir Henry Thompson, Mr. Savory, Mr. Bryant, and Mr. Hulke will probably take part.

IT is reported from Dongola that eight cases of small-pox have occurred among the troops forming the Nile Expedition. Every precaution against the spread of the disease has been taken, and the camping grounds where it first appeared have been changed.

DR. PARSONS, Local Government Board Inspector, has recently paid another visit to Kidderminster to supplement his previous inquiries regarding the typhoid epidemic. The number of deaths from the fever has exceeded ninety, and fresh cases continue to occur.

MR. JAMES WYLD, of Charing-cross, has issued a new map of Egypt, the Nile, and the Soudan, which will be found useful for reference in tracing the movements of the British forces sent for the relief of General Gordon.

IN consequence of the epidemic of measles in the city the Aberdeen School Board has decided upon the closure for a fortnight of the infant departments of all the elementary schools.

AT the meeting of the Medical Society of London on Monday next an important and interesting discussion on Anæsthetics is anticipated.

M. PASTEUR is reported to be about to proceed to Rio Janeiro in order to study the yellow fever.

DR. HUMPHRY has been re-elected representative of Cambridge University on the General Medical Council.

IRISH POPULATION STATISTICS.—From a supplement recently issued to the seventeenth report of the Registrar-General for Ireland we learn that the total number of births during the ten years 1871-80 was 1,402,277, the annual average being 140,228, or at the rate of 26·5 per 1000. The total deaths registered during the same period was 966,745, or at the average annual rate of 18·3. The total number of emigrants who left Ireland in the decade was 623,933, being an average of 62,393, or 11·7 per 1000 of the population per annum. A decrease, therefore, of 188,401 took place during the ten years, the real decrease up to the date of the last census (April, 1881) being 237,541.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN extraordinary meeting of the Council was held on Wednesday last to consider, first, Mr. Heath's motion respecting the election of the President and Vice-Presidents, and, next, the Recommendations of the Association of Fellows.

In the unavoidable absence of Mr. Heath the first part of this gentleman's motion was moved by Mr. Thomas Smith, and seconded by Mr. Allingham—viz.: "That the office of vice-president be for the future held for one year only by the same person."

It was put to the vote, when six voted for and fourteen against. The names having been taken, it was found that the supporters of the motion were Messrs. Holmes, Cadge, Smith, Sir William Mac Cormac, and Messrs. Allingham and Lawson, while those who voted against it were Mr. Erichsen, Sir Spencer Wells, Messrs. Marshall, Savory, Lund, Wood, Power, and Hutchinson, Sir Joseph Lister, and Messrs. Bryant, Hulke, Croft, Hill, and Durham. The President did not vote; Sir James Paget and Messrs. Heath and Sydney Jones were absent.

The second part of Mr. Heath's motion was moved by Sir William Mac Cormac, and seconded by Mr. Lawson—viz.: "That the president be elected annually by the Council from among its members, and that no president hold office for more than five consecutive years."

To this Mr. Cadge moved and Mr. Holmes seconded an amendment—viz.: "That the president be elected annually by the Fellows in a manner hereafter to be agreed on by the Council." Upon this the original motion was withdrawn and the amendment put as a substantive motion, whereupon Mr. Marshall moved and Mr. Wood seconded an amendment—viz.: "That the subject of the election of president be referred to the Committee on Charters and Bye-laws, to report thereon to the Council." This was ultimately carried.

After some discussion, it was resolved, on the motion of Mr. Marshall, seconded by Mr. Holmes, "That the communication of the Association of Fellows and the accompanying Recommendations be referred to the Committee on Charters and Bye-laws to report thereon to the Council." This Committee, it may be stated, consists of Sir James Paget, Mr. Erichsen, Sir Spencer Wells, Messrs. Marshall, Forster (President), Savory (senior Vice-President), Holmes (junior Vice-President), Lund, Cadge, and Smith.

ENTERIC FEVER AND MILK INFECTION AT ST. ALBANS.

THE report on this epidemic is made to the Local Government Board by Mr. Shirley Murphy, one of the officials of the Board in connexion with the Calf Vaccine Station. The population of the city is estimated by Dr. Saunders, medical officer of health, as 11,326; of 2500 inhabited houses 1890 are supplied by the St. Albans Water Company from deep wells, some two-thirds having a constant and the remainder an intermitting service, the same supply being delivered to all alike; the remaining 610 houses have private wells. St. Albans has a new system of sewers, and out of the 2500 houses, 1230 were connected with them at the beginning of the outbreak, the proportion of houses so connected to those unconnected being much the same in all the twelve portions into which the town is divided for sewering purposes. In the ten years 1874-83 only ten enteric fever deaths were registered in the city. Including for the purposes of the inquiry some 60 houses outside the borough with those in the city, it appears that on the whole area eight cases of enteric fever occurred during the first three months of the year, one of them taking place at a farm to be referred to. During May 86 cases occurred within the city boundary and 7 without the boundary; the number of houses infected during the same period being 58 and 4 respectively. In June 34 cases occurred within and 4 without the city, in 24 and 4 houses respectively. As regards any connexion between the disease

Digitized by Google

and the sewers, it appears that 34 of the affected houses or 2·7 per cent. were connected with the sewers, and that 48 or 3·7 per cent. were not so connected, and it was otherwise ascertained that the fever could not be related to any special condition of house drainage. Of the 82 houses, 74 had the company's water, 7 were supplied from wells, and the supply used by the remaining one is not known—that is to say, of the houses having the company's water 3·9 per cent. were attacked, and of those resorting to wells 1·1 per cent. But owing to the preponderance of one or another supply in different parts of the town it was soon seen that the difference between 3·9 and 1·1 had no particular importance in so far as the cause of the disease was concerned.

Dr. Saunders had at an early stage identified the disease with a certain milk-supply. The milk from the suspected farm was distributed by the dairyman himself and by seven different milk-vendors; and the customers of these various persons having been ascertained, it appeared that of 396 houses in and out of the city 86, or 21·7 per cent., were invaded during May or June; and during the same period there were but 4 houses out of the 90 invaded concerning which it could not be definitely stated that the milk came from the source in question; and as regards two of these the milk was admitted to have come from "various sources." In the city itself 21·1 of the houses supplied from this dairy farm were affected, and only 0·14 of the remainder. After dealing in detail with the seven vendors who sold this dairy farmer's milk, Mr. Murphy states that a maidservant who came to the farm in October, 1883, and who remained there till Jan. 24th, 1883, sickened with enteric fever two days after leaving. Another maid came on May 26th, and she sickened on June 10th. Some thirty visitors had also been at the farm, and of 25 inquiry as to illness was made, the result being that 2 were ascertained to have been attacked; but one of these drank milk at the farm in May, and the other received milk from there at about the same date. Some of the milk was also sent to London; but in the hands of one vender it was so used that it could not be identified and traced to customers; in those of another, six cases of enteric fever were heard of. Besides which an undue prevalence of the same disease was traced amongst persons in St. Pancras who were receiving their milk from the same source. In Islington, too, 15 per cent. of the houses supplied with this milk were attacked, whilst all others in the area which was subjected to investigation escaped. In short, both in and around St. Albans, and in London, there was a special incidence of enteric fever upon the consumers of this milk.

What gives such special interest to this epidemic is the fact that it was milk from the same farm that was the vehicle of distributing the infection of enteric fever during the serious outbreak of that disease which occurred in North London in 1883. It therefore became very important to learn, if possible, if any conditions about the farm could have led to it. Under these circumstances, the healthiness of every cow that had been milked for months past, the quality of their food and water, the health of *employés* both permanent and temporary, were investigated with much minuteness, but no clue to the disease could be obtained. After the 1883 epidemic a dangerous relationship between a well 100 ft. deep and a cesspit was brought under notice, the roots of a sycamore tree having been found to travel from one to the other. The cesspit had since been cleaned out and filled in, and on digging a trench about the privy no indication of soakage towards the well could be discovered. The inquiry, exhaustive and complete as it was, failed both in Mr. Murphy's and in Dr. Saunders' hands, in discovering any fresh source of contagium to account for the 1884 outbreak. But typhoid fever had not been thoroughly absent from St. Albans since the 1883 outbreak. During the closing months of the year five houses were invaded, four of which received their milk from this farm. Then, again, all the cases in the four houses attacked during the first quarter of this year, as also the servant girl at the farm itself, used this milk; and these facts, taken together with the 1883 epidemic on the one hand and the epidemic of May to June, 1884, on the other, go to point to some undiscovered source of infection which remained comparatively quiescent during some eight or nine months, and then, to use Mr. Murphy's words, gave rise to an intenser infectiveness, of which the outbreak in May and June was the result. Mr. Murphy's closing words repeat in effect what we have on several occasions strongly urged; and, written as they are in connexion with another fatal outbreak due to milk infection, they deserve to be specially noted. "Seeing that an infective quality can reside in milk produced under circumstances of reasonable cleanliness and healthiness, it comes to be of importance that English people should adopt, as their invariable rule in the use of milk, the custom, usual among Continental nations, of boiling all milk as soon as they receive it into their houses." Mr. Murphy's report deserves careful perusal, and we are glad to note that it is placed on sale as an official publication.

THE PROGRESS OF CHOLERA.

BETWEEN November 4th, when the first official announcement of the existence of cholera in Paris was made, and the 17th, the number of persons attacked concerning whom information had been obtained was about 1250, and the deaths during the same period numbered 617. Probably the returns as to non-fatal cases are very untrustworthy, otherwise the rate of mortality would be heavy, and this it has been asserted is not the case. Since November 10th, on which day the deaths numbered 98, there has been a diminution in the mortality, which has gradually fallen to about 30 a day, and the proportion of deaths to attacks has also undergone a very considerable reduction. That such a result should take place at an early stage of an epidemic appears to indicate that a further abatement is in prospect, and that the epidemic may be extinguished before long. It is sincerely to be hoped that, whether this is the case or not, no efforts will be spared, either in Paris or in other places that have been infected, to secure the removal of all conditions favouring nuisance in connexion with sewers, drains, cesspools, and accumulations of refuse, for it is these conditions that tend to favour the retention of the contagium, and which will enable it again to assume an active state when the warmer weather returns.

Rumours of cholera come also from other localities. In Algeria it is certainly not extinguished; odd cases appear to recur in the south of France; and news also comes of suspicious deaths in the provinces of Valencia and Toledo, and of the establishment of a cordon of Spanish troops round a town in the former province. Further statements have been made as to cholera in the Channel Islands, and even in London, but these are absolutely without foundation. As regards our own country, it is satisfactory to find from the recent speech of the President of the Local Government Board in Parliament that further measures are intended by his department with respect to the preparedness of ports to deal with imported cases. Our system of inspection and isolation requires for its efficient working that all sanitary authorities shall have the means of regular inspection and of isolation available, and as regards the port sanitary areas this is of importance.

OFFICIAL RETURN OF CHOLERA DEATHS IN PARIS.

The official weekly return on the statistics of the Paris municipality for the week ending the 12th inst. reports that 375 deaths from cholera were recorded in that period, raising the annual death-rate of the city to 32·8 per 1000, from 23·4 in the previous week. It is stated that the epidemic broke out on the 4th inst. simultaneously in two arrondissements, and afterwards spread in such a manner, that during last week only one of the twenty arrondissements escaped without a death. It is pointed out that the fatality of the disease has in the main been confined to the dirtiest streets and to the most uncleanly and poverty stricken of the population. With regard to some of the localities that are now suffering, it is stated that they have invariably suffered in previous epidemics, and that many of the worst streets are still in much the same condition as they were in at the beginning of the century. An especially severe outbreak occurred in an asylum for the aged, under the charge of a religious order, in the Avenue de Breteuil. Many of the other streets attacked have long been known as the hotbed of other zymotic diseases. In order to prove the slight individual risk of being attacked, the return gives a little table to show that only 14 per 100,000 of the Paris population died last week from cholera. The force of the epidemic may be better appreciated by us from the following facts:—The 375 deaths from cholera in Paris last week were equal to an annual rate of 8·6 per 1000 of the popula-

Digitized by Google

tion, and an equal rate of mortality in London would have there given 660 deaths. As regards the ages of the cholera victims, the small proportion of fatal cases among children is especially noteworthy; only 35 deaths occurred under fifteen years of age, 80 between fifteen and thirty-five years, 172 between thirty-five and sixty, and 88 among persons aged upwards of sixty years. The disease was far more fatal among men than among women; the deaths of males being 235, while those of females were only 140, or 17 males to 10 females. In the more recent cholera epidemics in England, in 1854 and 1866, the deaths of females exceeded those of males. The excess of males and of elderly persons among those dying from cholera in Paris last week was probably due in a great measure to the fatality of the disease in the asylum referred to above.

THE SMALL-POX HOSPITAL CASE.

THE action brought by Mr. Fleet, a property owner at Darenth, against the Metropolitan Asylums District Board to enforce the closure of the Darenth Small-pox Convalescent Camp, on the ground that there was danger of infection being carried from the camp to the plaintiff's property, has been concluded, and judgment has been delivered for the defendants. Mr. Justice Pearson, before whom the action was heard, in delivering judgment, said, assuming for the purposes of the judgment that it was possible that infection could be conveyed through the air, that was not a sufficient reason to grant an injunction in this case. He must, to do that, go much further, and come to the conclusion that it was probable that it could be so conveyed, and he was not able to arrive at that result. He said it had been argued that upon the balance of evidence it must be concluded that small-pox hospitals are the centres of infection, and because that was so in the case of the London hospitals it was so with this hospital; but the probable causes why in London there should be such danger did not apply to a hospital situated and managed as this was. In an early issue we shall take an opportunity of noticing this case at greater length.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Oldham Urban District.—Dr. Bryden Hill speaks with satisfaction of the reduction of the general death-rate, and also of the zymotic rate, during 1883, the former being 21·9, and the latter 1·5 per 1000 inhabitants, and he points out that the great efforts which have been made by the sanitary authority are now bearing fruit in the saving of many lives. Thus, compared with the average for the past ten years, there was in 1883, in a population of about 119,000, a saving of 500 lives, and this number includes no less than 333 lives which would otherwise have been sacrificed to zymotic disease. As regards this latter class of disease, much of the result is attributable to the joint working of the compulsory notification of infectious diseases and the isolation arrangements provided at the Westhulme Hospital. But there is great reason for regret that so large an infant mortality still reigns in the borough. Out of every 100 deaths 40 were of children under five years of age, and 25·5 under one year. Or, to put the case otherwise, out of every 1000 children born alive 159 were removed by death before attaining the age of twelve months. Such a mortality is certainly in part preventable, and the various conditions bearing upon it are considered in the report. Notably, reference is made to the neglect due to mothers working at mills, the consequent improper feeding, the conveyance of children through the streets early on frosty mornings when they have only just left their warm beds; and the need of the crèche system is strongly urged, in order to cope with some of the evils. Sanitary work progresses satisfactorily; and as regards infectious diseases, it is worth noting that 5317 articles were either disinfected or destroyed, that 1072 rooms and 358 houses were cleansed and disinfected, and that 135 cases were admitted into the Westhulme Sanitary Hospital during the year.

Runcorn Rural District.—The death-rate was 17·5 per 1000 during 1883. Certain instances of choleraic diarrhœa led to a careful examination of the sanitary circumstances of this district, which lies so near to the port of Liverpool, and to a report on the filthy state of the Kingsley brook, which, it is believed, is sometimes resorted to for drinking purposes. Certain preparations were also made as to the mooring of any infected vessels, and it was resolved to purchase an iron hospital to be put up in case of need. The removal of cases of typhoid to the workhouse hospital, and the spread of scarlet fever, show that this need has long since arisen, and it is to be hoped that if the iron hospital has been purchased a site has also been obtained for it, for more than once such temporary hospitals have failed at a critical moment for lack of a site.

Birkenhead Urban District.—This borough, with an estimated population of 88,700, had in 1883 a birth-rate of 35·45 and a death-rate of 19·95 per 1000. The latter is calculated without corrections for deaths at sea &c.; and only seven of the cities and boroughs quoted by the Registrar-General had a lower rate. The rate of infant mortality was 155 under one year per 1000 births. Under the section of the Local Act of 1881, relating to the notification of infectious diseases, 874 cases were notified to the sanitary authority; 789 cases were notified by medical practitioners, 69 by school attendance officers, 6 by occupiers, and 10 by the registrars. But having regard to the relation which these numbers bear to the registered mortality from the causes specified, Mr. Vacher says that there is no avoiding the conclusion that a certain residuum of cases still escape unreported. On the whole, the zymotic death-rate was 1·28 less in 1883 than the mean of the zymotic death-rate during the five preceding years, and this included an outbreak of typhus which was checked by isolation and disinfection; and to the working of compulsory notification is attributed in part both this result and the lowering of the zymotic mortality. In view of the increasing demand for isolation in hospital, the villa hospital, which was one of the first established, has been found inadequate. A site capable of containing two pavilions of ten beds each has been appropriated. One pavilion is already erected, and it is hoped that the other may soon be put up. In view of this anticipation we would point out how in some respects the second pavilion may be made an improvement on the first. Two of the end beds in the existing building are in a corner, the beds touching the wall. Corners in infectious wards should always be lighted by a window, and every bed should stand in a wall-space between two windows. Besides which, in calculating floor area per bed, the amount of wall space is the most important element, for no excess of space down the centre of the ward can possibly compensate for diminution of the area where the patients' heads lie, and where they hence take in the greater part of the air they breathe. Every bed should stand in the centre of its own 12 ft. of wall space. Then again, a single fireplace for a ward measuring nearly 50 ft. in length must produce very unequal heating, and if it succeeds in adequately warming the distant end of the ward it must certainly give out an excessive heat near the fireplace. There are few modern infectious hospitals where some 25 ft. have not been regarded as the maximum length of ward for a single fireplace; and if two open fireplaces are not provided, one at either extremity, a central stove having two open fireplaces facing either end of the ward is, as a rule, provided. The solid wall, which is shown in the diagram between the two waterclosets, implies a partition, which prevents cross ventilation by means of the two closet windows. As a rule, a wooden partition, some 7 ft. high and not touching the ground, is preferred with a view of securing the requisite cross current. In the main the hospital is well designed, and will serve a useful purpose.

St. George, Hanover-square.—There is a continually decreasing death-rate in this parish, and the rate for 1883 was only 15·7 per 1000—that is to say, it was less than in any of the large towns of England. It must be remembered, however, that the district contains a specially selected population, and hence, forming as it does a picked portion of a large city, it can hardly be compared with any town or city as a whole. A large portion of the report is merely statistical, and apart from a summary supplied by the inspector of nuisances, it contains but little information of the sanitary circumstances of the district.

Digitized by Google

St. Mary, Newington.—Dr. Iliff's annual report forms a part of a general report on the proceedings of the vestry. In 1883 the death-rate on 110,000 people in this parish was 23·1 per 1000, but the conditions leading to preventable death amongst this large population are only very incidentally referred to. There is some information as to certain drain defects, a summary of hints issued in anticipation of cholera, a reference to legislation which was proposed last session, and some general statements as to the housing of the poor; but, like many other London reports, this one but very imperfectly resembles the excellent annual reports which come from many of our other populous cities and boroughs.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5850 births and 3505 deaths were registered during the week ending the 15th inst. The annual death-rate in these towns, which had been equal to 20·6 and 21·3 per 1000 in the two preceding weeks, declined again last week to 20·9. During the first seven weeks of the current quarter the death-rate in these towns averaged 20·7 per 1000, against 21·3 and 20·5 in the corresponding periods of 1882 and 1883. The lowest rates in these towns last week were 14·0 in Huddersfield, 14·8 in Brighton, 17·9 in Derby, and 18·4 in Bradford. The rates in the other towns ranged upwards to 27·8 in Bolton, 27·8 in Preston, 28·6 in Newcastle-upon-Tyne, and 30·0 in Wolverhampton. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 379 and 392 in the two preceding weeks, declined last week to 369, and were fewer than in any previous week of this year; they included 73 from scarlet fever, 63 from measles, 57 from "fever" (principally enteric), 56 from diarrhœa, 52 from whooping-cough, 39 from small-pox, and 29 from diphtheria. No death from any of these principal zymotic diseases was recorded last week either in Brighton, Plymouth, or Wolverhampton; whereas they caused the highest death-rates in Newcastle-upon-Tyne, Bolton, and Cardiff. The greatest mortality from scarlet fever was recorded in Sheffield and Newcastle-upon-Tyne, from measles in Bolton and Cardiff, from "fever" in Leeds, Preston, Portsmouth, and Derby, and from whooping-cough in Oldham and Sunderland. The 29 deaths from diphtheria in the twenty-eight towns included 17 in London, 4 in Liverpool, and 2 both in Norwich and in Newcastle-upon-Tyne. Small-pox caused 56 deaths in London and its suburban districts, 2 in Birkenhead, and 2 in Sunderland. The number of small-pox patients in the metropolitan asylum hospitals, hospital ships, and convalescent camps, which had been 580 and 669 on the two preceding Saturdays, further rose to 749 at the end of last week; 199 new cases were admitted to these hospitals during last week, against 101 and 233 in the two previous weeks. The Highgate Small-pox Hospital contained 41 patients on Saturday last, 20 new cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had increased in the eight preceding weeks from 159 to 357, further rose last week to 370, but were 85 below the corrected weekly average. The causes of 79, or 2·3 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bristol, Bradford, and in six smaller towns. The largest proportions of uncertified deaths were recorded in Halifax, Oldham, and Salford.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased from 21·3 to 22·6 per 1000 in the four preceding weeks, declined to 22·3 in the week ending the 15th inst.; this rate was, however, 1·4 above the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns ranged from 14·8 and 16·8 in Leith and Aberdeen, to 23·6 in Greenock and 25·7 in Glasgow. The deaths in the eight towns included 103 which were referred to the principal zymotic diseases, against 116 and 93 in the two previous weeks; 23 resulted from measles, 22 from diarrhœal diseases, 19 from scarlet fever, 16 from whooping-cough, 13 from diphtheria, 10 from "fever" (typhus, enteric, or simple), and not one from small-pox. The rates from these diseases in the Scotch towns last week ranged from 0·0 in Perth and 2·8 in Dundee, to 4·7 in Leith and Aberdeen and 6·8 in Glasgow. The 23 deaths from measles showed a further increase upon recent weekly numbers, and included 12 in Glasgow and 9 in Aberdeen. The 22 deaths attributed to diarrhœal diseases all but corresponded with the numbers in recent weeks, and exceeded by 8 the number returned in the corresponding week of last year. Twelve of the 19 deaths from scarlet fever occurred in Glasgow. The fatal cases of diphtheria showed a decline, while those of whooping-cough were more numerous. The 10 deaths from "fever" exceeded the number in the previous week by 4, 7 occurring in Glasgow and 3 in Edinburgh. The 101 deaths referred to acute diseases of the respiratory organs in the eight towns showed an increase of 3 upon the low number in the previous week, but were 47 below the number returned in the corresponding week of last year. The causes of 73, or nearly 14 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 24·7 and 25·3 per 1000 in the two previous weeks, further rose to 30·0 in the week ending the 15th inst. During the first seven weeks of the current quarter the death-rate in the city averaged 27·4 per 1000, whereas it did not exceed 18·9 in London and 18·4 in Edinburgh during the same period. The 202 deaths in Dublin last week showed a further increase of 32 upon the number in the two previous weeks, and included 25 which were referred to the principal zymotic diseases, against 29, 25, and 18 in the three previous weeks; 10 resulted from scarlet fever, 9 from "fever" (typhus, enteric, or simple), 3 from whooping-cough, 2 from diarrhœa, 1 from measles, and not one either from small-pox or diphtheria; these 25 deaths were equal to a zymotic death-rate of 3·7 per 1000, the rate from the same diseases not exceeding 2·2 in London and 3·2 in Edinburgh. The deaths from scarlet fever in Dublin, which had been 12, 10, and 8 in the three previous weeks, rose again to 10 last week. The fatal cases of "fever," and of whooping-cough, also showed a considerable increase upon the numbers returned in the previous week. Eight deaths were referred to violence, and 51 deaths were recorded in public institutions. The deaths both of infants and of elderly persons showed a marked increase upon recent weekly numbers. The causes of 33, or more than 16 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

WAR OFFICE.—Grenadier Guards: Surgeon Albert Luis Fernandes retires from the service, receiving a gratuity.

ADMIRALTY.—Deputy Inspector-General of Hospitals and Fleets Thomas John Breen has been placed on the retired list, with permission to assume the rank and title of Inspector-General of Hospitals and Fleets.

Staff Surgeon Fleetwood Buckle has been appointed to the *Alexandra*, additional, for Marines at Suakin.

RIFLE VOLUNTEERS.—1st Wiltshire: Surgeon Thomas Jarvis Bennett, M.D., is granted the honorary rank of Surgeon-Major.—2nd Volunteer Battalion, the South Staffordshire Regiment: Surgeon James Clark, M.D., is granted the honorary rank of Surgeon-Major.

SOCIAL SCIENCE ASSOCIATION.—At a meeting of the Council of this Association held on the 13th inst., the following resolutions were unanimously carried—1. "That this Council learns with satisfaction that a proposal has been submitted for the consideration of his Royal Highness the President, and the Executive Council, for employing the surplus which may be found to exist on the closing of the accounts of the International Health Exhibition for the purpose of maintaining and continuing the biological health laboratories and the library as essentials to the study and teaching of correct sanitary work." 2. "That in the opinion of the Council of this Association the opportunity is a favourable one for establishing closer relations between the various organisations which at present exist for the diffusion of sanitary knowledge and the application of sanitary science."

"Audi alteram partem."

THE APPOINTMENT OF SURGEON-GENERAL OF THE PUNJAB.

To the Editor of THE LANCET.

SIR,—I venture to think that a knowledge of all the facts of the case will lead you to modify the opinion you expressed in THE LANCET of Nov. 15th on the selection of Dr. Dallas for the appointment of Surgeon-General of the Punjab. You are doubtless not aware that for the long period of eighteen years Dr. Dallas performed all the duties which now devolve on the Surgeon-General without getting a sixpence of remuneration for doing so, but such is the fact. In 1862 he was appointed Inspector-General of Prisons, an office to which was attached the supplementary duty of inspecting the dispensaries and civil hospitals of the province. At that early period of British rule in the Punjab the work was light, as the dispensaries were few in number; but under Dr. Dallas's administration they increased rapidly, and after a few years the number of patients attending them were counted by tens of thousands, and the capital operations performed, including about 500 lithotomies, amounted to several thousands a year. The financial as well as the medical administration of these institutions was carried on entirely by Dr. Dallas, in addition to his own proper work—namely, the inspection and administration of the prisons of a province of seventeen millions of inhabitants, and for this extra work he did not receive a shilling of extra pay. By 1874 the civil hospital work had become so heavy that the Punjab Government felt that it was not reasonable to ask the Inspector-General of Prisons to attend to it any longer, and they requested the Government of India to constitute the administration of the civil hospitals an independent charge. For reasons of economy this request was not complied with till 1880, when the office of Surgeon-General was created with a salary considerably higher than that which Dr. Dallas had enjoyed for the performance of the duties now devolved on the Surgeon-General in addition to those of Inspector-General of Prisons. I think, Sir, you will admit that under these circumstances Dr. Dallas might fairly have expected the new appointment as some acknowledgment of his many years of unremunerated toil, and the Punjab Government at the time earnestly pressed his claims on the Government of India, but without success. The claims of seniority prevailed. Dr. Dallas, relieved of the administration of the civil hospitals, was charged only with the duties of the Inspector-General of Prisons, and thereafter two officers were allotted for work which he had done alone for the long period of eighteen years. Since 1880 there have been two Surgeons-General in the province, and when the second vacancy occurred last month the Punjab Government, finding doubtless that such frequent changes were not conducive to the public interest, very properly, as I think, renewed their application for the appointment of Dr. Dallas, and the Government of India acceded to their request. Dr. Dallas had for many years carried on the work with conspicuous success and zeal, and with such patient modesty that neither the Government nor the public had any correct idea of the valuable services he was rendering.

I cannot conclude without mentioning another strong claim Dr. Dallas has to special consideration. It is that to him belongs the merit of having first demonstrated the practicability and advantage of establishing a system of vital statistics in India. In 1864 he prepared a scheme for the registration of deaths in the Punjab, which was at once brought into operation. Nothing of the kind had ever been previously attempted in any other province. The scheme was at first ridiculed as impracticable and useless, but the result has shown that this opinion was entirely wrong, and Dr. Dallas's method of procedure has been found so sound and so well adapted to the circumstances of the country that it has been adopted, with slight modifications, in all the other provinces of the Indian Empire. As it devolved on me to take up this branch of his work when I was appointed Sanitary Commissioner in 1868, I feel I have some right to speak of the value of his services in the matter. For many years he was the referee of the Government in all sanitary questions, and while he only received the salary of one office he did the work of three—namely, that of Inspector-General of Prisons, Surgeon-General, and Sanitary Commissioner. I have only, in conclusion, to express my firm assurance that Dr. Dallas's appointment as Surgeon-General is fully justified on the grounds of the public interest and the recognition due on the part of the Government for his most valuable services.—Your obedient servant,

A. C. C. DE RENZY,
November, 1884. Surgeon-General.

*** Though Dr. De Renzy makes out a very good case for Dr. Dallas's promotion, we are scarcely prepared to admit that it justifies the course followed, for a second time in the Indian service, of giving two steps in such rapid succession, and over the heads of so many seniors, some of whom have also been distinguished for zealous and efficient service.—ED. L.

CHARCOT'S JOINT DISEASE.

To the Editor of THE LANCET.

SIR,—May we, through you, draw the attention of your London readers to the fact that an adjourned discussion on Charcot's Joint Disease will take place at the Clinical Society's meeting on Nov. 28th. There will be the usual opportunity for exhibiting living specimens at 8 P.M.; and the Society will be grateful to any of its members who can show illustrative cases, more especially examples of typical rheumatoid arthritis, combined with ataxia, or typical Charcot's arthropathy without ataxia.

We may add that Professor Charcot has promised to send over for the occasion a series of preparations from his own private collection, to illustrate the disorder and its specific characters.—We are, Sir, yours faithfully,

SIDNEY COUPLAND, } Hon. Secs.
R. J. GODLEE, }

Clinical Society of London, Berners-st., Nov. 18th, 1884.

"DEATH DURING THE ADMINISTRATION OF METHYLENE."

To the Editor of THE LANCET.

SIR,—After reading Dr. Buchan's letter in your last issue on Death during the Administration of Methylene, I am led to ask: "What is methylene?" Dr. Buchan says "that a sample of the methylene used was tested and found to be pure." I suppose therefore that he will be able to give some account of it, and of the tests he employed. Some years ago I had occasion to point out that the so-called chloride of methylene was simply impure chloroform, and that methylene chloride, CH_2Cl_2, could not be prepared except at a cost which would place it entirely beyond reach for ordinary use as an anæsthetic. If the article which is now being sold as methylene or methylene chloride be, as I suspect, nothing more than impure chloroform prepared from methylated spirit, it is more than probable that it contains chlorinated derivatives of acetone, which are likely to be anything but harmless. I have no hesitation in affirming that all chloroform for anæsthetic purposes should be prepared from pure alcohol alone.

I am, Sir, yours truly,

Granville-park, S.E., Nov. 18th, 1884. HENRY E. ARMSTRONG.

THE CONJOINT EXAMINATION SCHEME.

To the Editor of THE LANCET.

SIR,—I fear the new examination scheme of the English Colleges of Physicians and Surgeons will, unless modified, tend to perpetuate one of the weak points of ordinary English medical education. In almost every other country instruction in science precedes instruction in subjects purely medical, and in our universities the examinations are so arranged that the student is encouraged to acquire a knowledge of chemistry before he commences to study physiology. But it appears that in the new scheme the student's first examination is to include chemistry as well as anatomy, physiology, and materia medica, and he will thus be led to attend lectures on the first three of these subjects simultaneously, as heretofore. This combination is objectionable on several grounds. An average first year's student cannot

Digitized by Google

give due attention to all these subjects at once, and chemistry is habitually neglected, as most lecturers at medical schools know only too well. Again, some knowledge of chemistry is essential to the due comprehension of lectures on physiology; but how can this knowledge be secured if instruction in the two subjects commences simultaneously? Lastly, the combination of chemistry with anatomy and physiology leads students to enter a medical school at an earlier age than they would if attendance on chemistry were made to precede studies purely medical. Education is hardly advanced enough in England for all the examining boards to insist on such preliminary instruction in science as is required abroad; but surely a movement in the right direction may now be initiated by *allowing* students to pass the examination in chemistry and chemical physics before entering on their medical studies. They would thus be encouraged to work at purely scientific subjects in the year preceding their attendance on anatomy and physiology. If the present combination of subjects is made compulsory, students who do this will be placed at a disadvantage, since the examination in chemistry will be separated from the antecedent course of instruction by more than twelve months.

I am, Sir, yours truly,

Owens College, Manchester, Nov. 17th, 1884. D. J. LEECH.

THE RECENT ESCAPE FROM BROOKWOOD ASYLUM.

To the Editor of THE LANCET.

SIR,—As it would appear, from the sensational statements in various newspapers, that the patient who escaped from this asylum on the 10th inst. was not a fit case for detention here, I venture to send you the following facts:—The patient in question has been insane for many years, and previous to his admission here had been in two asylums in America, from one of which he escaped, and eventually made his way to England. He is a quiet and harmless man, but the subject of well-marked delusions. He has been in the habit for some time past of going out with the attendant who posts the mid-day letters, and on the afternoon of the 10th gave the attendant the slip, concealed himself until dark in the woods, and eventually walked to London. He presented himself to the American Consul the next day, asserting that he was perfectly sane and illegally detained here. Mr. Lowell promised to investigate his case, and prevailed upon him to return to the asylum, which he did, after an absence of forty-eight hours. This man's mental condition is well known to the Commissioners in Lunacy, and to the Visiting Justices of the asylum, and they concur in my opinion that he is a fit case for asylum care.

Yours faithfully,

JAS. E. BARTON,
Medical Superintendent.

Surrey County Asylum, Brookwood, Woking, Nov. 18th, 1884.

THE NEW ANÆSTHETIC—CUCAIN.

To the Editor of THE LANCET.

SIR,—For some time several laryngologists have been employing a salt of cucain for the purpose of producing local anæsthesia. At the recent Ophthalmic Congress its value was demonstrated, and many surgeons have since used it in operations on the eye and other parts. A weak solution of the muriate (2 or 4 per cent.) produces anæsthesia of mucous membranes sufficient to enable operations to be performed without pain. A stronger solution is sometimes required. It is only necessary to paint the part with a camel-hair brush once, twice, or thrice, at intervals of three to five minutes, when local anæsthesia is produced, lasting from fifteen to twenty minutes, sometimes half an hour. The value of such an agent is manifest, for it gives no pain whatever. Painless operations for cataract, squint, &c., have been done after a couple of such instillations. I have had repeated success with this anæsthetic in depriving the fauces of sensibility, in removing excessive irritability of these parts for operative purposes, and to-day it has furnished me great assistance in the intra-laryngeal manipulations of an unusually difficult case of growth in the larynx.

I have spoken of the alkaloid as cucain. It is the active principle of cuca erythroxylon, more often called coca. Sir R. Christison proposed to spell it cuca, and as that represents the pronunciation of the natives, and serves to distinguish it more completely from other substances, it is to be hoped his suggestion may be more generally followed than hitherto.

I am, Sir, yours truly,

Dean-street, Park-lane, Nov. 18th, 1884. PROSSER JAMES.

SURGICAL ERYTHEMA.

To the Editor of THE LANCET.

SIR,—*A propos* of Dr. de Havilland Hall's interesting communication to the Medical Society on Scarlet Fever in Surgical Cases, I have now under my care a child about three years old suffering from an injury to the head, resulting in abscess beneath the scalp and general erysipelas of the face. Before the latter had subsided a scarlet rash appeared over the trunk and thighs, resembling the efflorescence of scarlet fever, but presenting to the touch the feeling of grains of sand; there was no perceptible exacerbation of pyrexia, or increase of temperature. The following day the rash had nearly disappeared, leaving patches of deep red papillæ on the thighs. There has been no subsequent desquamation. If I may venture to offer an opinion on Dr. Hall's case, I should think the child had been subjected unknowingly to the infection of scarlet fever either previous to the operation or soon after, proclivity to the disease being increased by the depressing effect of an operation. Desquamation is certainly a pretty conclusive proof of the nature of the attack.

I am, Sir, yours obediently,

Queen's-park-terrace, W., Nov., 1884. J. HAWKES, M.D.

LIVERPOOL.

(From our own Correspondent.)

THE CITY CORONER'S COURT.

IN the last annual report of the head constable is a table (No. 31) giving a return of all inquests held before the city coroner from the 30th September, 1883, to the 29th September, 1884. The following are details extracted from it. There were in all 1584 deaths referred to the coroner. In 855 he decided that an inquest was not required, and in 729 inquests were held. Of this number 486 were on the bodies of males, 243 on females, 168 were infants under one year, of whom 150 were legitimate, 18 illegitimate. The findings of the jury were—murder 10 cases, manslaughter 7, suicide 38, accidental death 402, of which 260 were those of males, 142 females; injuries (cause unknown) 47; found dead 57; excessive drinking—males 47, females 26; disease aggravated by neglect 3, from want, cold and exposure, &c. 4; other causes 88. The total cost of these 729 inquests was £2357 13*s.* The present coroner, Mr. Clarke Aspinall, J.P., has held office since 1867. He is a solicitor, paid by salary, which has been gradually raised up to its present amount of £1500 per annum. He does not practise, devoting his whole time to the duties of his office, and to assisting the stipendiary magistrate. With the exception of the borough gaol, which, though situated in the district of the county coroner, is by a local Act included in the borough coroner's district, all inquests are held at the coroner's court, situated within the police buildings, in which are also the magistrates' courts, the head constable's and detective offices, &c.

THE LADIES' CHARITY AND LYING-IN HOSPITAL.

With the exception of the Royal Infirmary the Ladies Charity is the oldest of the medical charities of Liverpool, having been established nearly a century ago as a maternity charity for attendance on poor married women at their own homes. It was amalgamated with the Lying-in Hospital in 1869. Lately a new hospital has been erected on Brownlow-hill, a central and convenient thoroughfare. It will be for the reception of labour cases, and is to be opened to-day by the Countess of Sefton. Fuller details will be forwarded in a future letter.

THE WINTER ASSIZES.

Mr. Justice Day has been sitting since the 13th inst., trying the prisoners in what is rather a heavy calendar. There are four cases of murder, and many where the knife and brutal violence have been used. In all cases where he has power to do so Justice Day sentences those charged with

Digitized by Google

robbery accompanied by violence to short terms of imprisonment and the infliction of the lash. In a very large proportion of cases drink has been the cause of the crime.

Liverpool, Nov. 19th, 1884.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

NEWCASTLE-ON-TYNE.

THE returns of infectious diseases for the last fortnight ending November 8th, and notified to the medical officer of health for the city by practitioners, show a total of 130 cases; of these 106 are put down to scarlet fever, which shows, when taken with the death-rate, that this disease has taken a rather serious epidemic form. The House Committee of the Infirmary announced at their late meeting that His Royal Highness the Prince of Wales had consented to become the patron of the infirmary, an office which has not hitherto existed in association with the institution. His Royal Highness at the same time enclosed a donation of fifty guineas. The city engineer and the medical officer of health, Mr. H. E. Armstrong, have just presented to the City Council a report on the water-supply of Newcastle-on-Tyne and district, which may indeed be said to be opportune, exhaustive, and suggestive. The report is accompanied by tables of analyses, maps of the gathering grounds for the water, and also diagrams showing its distribution. The report may be said to have sprung out of a letter by Dr. Huntley, sent to the Town Council in January last, and complaining of the sewage contamination of the water-supply. The city engineer and the health officer were requested to inquire into the causes of complaint, which they have done in a very able manner, and have likewise presented a mass of facts elicited in their inquiry likely to prove of great value as to the storage, conveyance, and distribution of water. The total area from which the supply is derived is about 22,000 acres, of which fully nine-tenths are pasture and moorland. The number of inhabitants is small, being about 1820, or 0·06 per acre. The number of stock is of course considerable, and is estimated at about 11,000 on the average, or 0·50 per acre. While, therefore, it is by no means an ideal gathering ground, it will bear favourable comparison with those of many larger and more important cities. The amount of water delivered each day averages 13,000,000 gallons. The population to be supplied, or that has yet to be supplied, by the water company amounts to 370,000, and gives a consumption per head for all purposes of 38½ gallons. The medical officer of health of course enters very fully into the question of purity, and it is satisfactory to us to know that, although the water is not what it should be, or indeed might be, yet upon the whole a range of tests and examinations shows it to be fairly good and wholesome. Mr. H. E. Armstrong, however, points out many defects, and makes suggestions for their removal; and there can be no doubt that if his recommendations and those of the engineer are attended to we shall have a water-supply in point of quality and quantity little, if at all, inferior to any city in the kingdom.

THE HUDSON BEQUEST TO SUNDERLAND.

This munificent bequest, although somewhat limited in its operation by the terms of the will, is likely very soon to prove a great blessing to many in the borough. The trustees have now been appointed, and they have advertised for a superintendent to begin the operations of the charity. It appears that, so far, after calling in all the late Mr. Hudson's effects, there will remain the handsome sum of at least £160,000, available to support, clothe, and educate the orphan children of pilots and of others connected with the sea. No part of the funds, it is expressly laid down, is to be devoted to the erection and purchase of any building. Orphans are defined to be children whose fathers are dead or paralysed.

SMALL-POX IN DURHAM CITY.

In view of the continuance and spread of small-pox in the city of Durham application has been made to the authorities for the use of the Durham militia barracks as a temporary hospital, and this has been granted under certain conditions, so that at last the city is provided with an infectious diseases hospital. The local papers are full of letters from dissatisfied writers as to the choice made by the sanitary authority of the barracks; but in fact there was no choice, and the barrack appears to be the only available building for the purpose. It certainly is dangerously near some of the dwellings of the poorer classes; and unless an infectious hospital be erected in a very isolated situation, it must always be looked upon as a disagreeable neighbour.

CARBOLIC ACID POISONING AT MORPETH.

An inquest has been held in the board-room of the Morpeth workhouse on the body of an inmate who died after swallowing a quantity of carbolic acid. It came out in evidence that he had been an engine-fitter, was in his seventy-second year, and had been a patient in a lunatic asylum. He confessed to another inmate, about two hours before he died, that he had taken the carbolic acid from the workhouse scullery, where it was open to anyone.

LEAD-POISONING AT SOUTH SHIELDS.

At a late meeting of the South Shields Board of Guardians Dr. Drummond reported a fatal case of lead-poisoning which had occurred in the Westoe district. The person had been employed at the Hebburn works.

Newcastle-on-Tyne, Nov. 19th.

PARIS.

(From our own Correspondent.)

THE CHOLERA EPIDEMIC.

The cholera epidemic is of course the all-absorbing topic of the day. I am glad to be able to say that the disease is not extending; but, on the contrary, it is limited to the quarters where it originated; and if one may judge from the number of the fresh cases that occur, and which are diminishing daily, one may predict a short life for the epidemic. The number of cures is also greater, and the mortality considerably less in proportion to what it was at the commencement of the epidemic. For instance, on the first day of the outbreak—that is, on the 4th inst.—there were 2 deaths, and on the 16th there were 92 in and out of the hospitals. Taking the hospitals alone, the official report for the 16th and 17th inst. shows that the number of admissions on the 16th was 34 (25 men and 9 women), against 70 of the previous day. The number of deaths fell from 49 on the 15th to 33 (20 men and 13 women) on the 16th. Thirteen patients left the hospitals cured, which, added to the cases that left on the 14th and 15th, make a total of 52. On the 17th the admissions were 37 (24 men and 13 women) and the number of deaths 25 (16 men and 9 women). The number cured amounted to 34. The total number under treatment in the hospitals on that day amounted to 348. The number of cases affected with the disease in Paris from the 4th to the 17th inst. amounts to 1500, and the number of deaths to 695, which, compared with the population, which is estimated at 2,239,000, is considered a small proportion. From the provinces likewise the reports are more favourable. At Ypert two deaths were reported on the 18th inst. At Nantes there were 3 fresh cases on that day, and 39 under treatment. No new cases have been reported within the last two or three days from Toulon.

A DANGEROUS EXPERIMENT.

Dr. Bochefontaine, chef of Professor Vulpian's laboratory, lately tried some experiments on himself with the view of proving the inefficiency of the comma bacillus to produce cholera, and that cholera dejecta are neither infectious nor contagious. He swallowed pills composed of four cubic centimetres of diarrhœic fluid from a patient, a woman of thirty-five, who died in Professor Vulpian's ward with the characteristic symptoms of cholera. No effect was produced on the day of experiment, but on the following day the venturesome physician was seized with symptoms of malaise, expressed by a feeling of feverishness, fulness of the head, and rumbling of the bowels, unaccompanied, however, with diarrhœa; there was some fulness of the stomach with nausea. It must also be noted that slight dysuria also manifested itself, but on the next day he was quite well again. This experiment, however, far from proving the innocuity of the pills that the doctor swallowed, is in

Digitized by Google

my opinion rather confirmatory of Dr. Koch's theory of the pathology of cholera, for the symptoms he experienced were evidently those of the incipient stage of the disease, and I do not believe he would be so foolhardy as to try such a dangerous experiment on himself again, especially as those tried on two guinea-pigs and a dog with the same fluid injected subcutaneously were sufficiently conclusive, both the animals dying with symptoms of cholera.

Paris, Nov. 19th.

MEDICAL NOTES IN PARLIAMENT.

Alleged Lunatics.

IN the House of Commons on Friday, the 14th inst., the Lord Advocate, in reply to Dr. Cameron, who asked a number of questions relative to the case of Thomas Harrison, who escaped from Cheadle Lunatic Asylum, Manchester, and made his way to Glasgow to have his sanity investigated under the safeguards of the Scotch law, stated that if Harrison was still in Scotland he would have the same protection as any other citizen and the same legal remedies.

In reply to Mr. Corbett, who asked the Home Secretary whether his attention had been called to a report in the newspapers of the escape of an American gentleman named Bruce from the Brookwood Lunatic Asylum, Sir William Harcourt stated that he had no knowledge whatever of the case, but it would be inquired into.

Dublin Hospitals.

In reply to Mr. Power, who asked whether it was the fact that there was no duly qualified compounder of medicine in the Rotunda Hospital, the Coombe Hospital, or the Pitt-street Institute, Dublin, Mr. Campbell-Bannerman stated that the two hospitals alluded to had an arrangement with an eminent firm of dispensing chemists for the compounding and dispensing of medicines, and that in the few intern cases at the Rotunda Hospital where medicines are necessary they are made up under the supervision of the master and the assistant physician. Regarding the Pitt-street Institute, he could supply no information.

Cholera Preparations.

On Monday, replying to Mr. Moore, Sir C. Dilke stated that the Local Government Board have caused inspection to be made by Dr. Blaxall and Dr. de Chaumont of the sanitary condition of the principal English ports, particularly with reference to their preparedness against cholera, and that recently a conference took place between representatives of the Metropolitan Asylums managers and members of the medical staff of the Local Government Board to consider the question of arrangements in the event of an outbreak in London.

Over-pressure in Board Schools.

In reply to Mr. Stanley Leighton, Mr. Mundella stated that he could not admit the accuracy of the fact that the National Union of Elementary Teachers, representing 13,000 teachers, had endorsed the conclusions of Dr. Crichton Browne and condemned the report of Mr. Fitch; indeed, he was daily in receipt of evidence from teachers, many of whom are members of the National Union, entirely dissenting from the views set forth in Mr. Heller's letter. Seeing that the London School Board had the whole matter under their consideration, he could not reconsider his refusal to institute an inquiry by impartial medical men into the grievances complained of.

Surgeons-Major in the Army.

In reply to Colonel Walrond, the Marquis of Hartington stated that it is distinctly laid down in the Royal Warrant that surgeons-major are to be selected for promotion to the higher ranks of the medical staff. Under such a system, therefore, promotion is not necessarily the rejection of an incompetent officer, but the selection of the most competent officer; and he was not prepared to admit that that officer is passed over who does not happen to be selected for advancement, nor did he see that such officer is entitled to have notification made to him of his non-selection.

Accommodation in Lunatic Asylums.

In reply to Mr. A. O'Connor, Sir William Harcourt stated that his attention had been called to the case of the woman who had been sent to a private lunatic asylum by the Paddington guardians, in consequence of there being no accommodation in the three county asylums of Hanwell, Colney Hatch, and Banstead. The inadequate accommodation in the county asylums had been several times brought to the attention of the justices by the Lunacy Commissioners, and he would do everything in his power to secure proper accommodation being provided. In the particular case in question, the husband of the lunatic would pay no more than if his wife had been placed in a public asylum.

Examinations for the Army Medical Department.

On Thursday, Mr. Sheil asked the Secretary for War whether he would lay upon the table a return of the marks made by candidates at the last two examinations for the Army Medical Department; whether the vacancies have, in all cases, been filled by those candidates who obtained the highest marks in the competitive examination; why information as to the number of marks gained by unsuccessful candidates in the examination for the Army Medical Department is refused; and whether he is aware that this information is supplied to candidates for the Navy Medical Department. The Marquis of Hartington, in reply, said he could not undertake to give a return of marks at the last two examinations for the Army Medical Department. The marks of the successful candidates have already been published; but for obvious reasons it is not the practice in any examination to give the marks of unsuccessful candidates, unless they can be designated by numbers. In the examinations for the Medical Staff the candidates are examined by name, and no numbers are assigned to them. The vacancies have in all cases been filled by those candidates who obtained the highest aggregate of marks in the compulsory subjects without failing to reach the standard in any of them. This was in accordance with the published terms of the competition. Marks in the voluntary subjects have only a value in determining the place of the candidate on the list of those successful in virtue of their marks in the compulsory subjects. He understood that information as to the number of marks gained by unsuccessful candidates was refused in consequence of the wish of the examiners, but he saw no sufficient reason why a candidate should not, on his application, be informed of the marks he gained, and he would give directions accordingly. He understood that similar information was afforded in the case of the Naval Medical Department.

Medical News.

UNIVERSITY OF LONDON.—The following candidates have passed the recent M.B. Examination:—

FIRST DIVISION.

Anderson, George Elliott Caldwell, Guy's Hospital.
Bennett, Fred. William, Owens College and Manchester Royal Infirmary.
Bowes, William Henry, Guy's Hospital.
Cockey, Edmund Percival, St. Mary's Hospital.
Crookshank, Edgar March, King's College.
Day, John Roberson, University College.
Dent, Harry Lord Richards, King's College.
Glover, John Philip, St. Thomas's Hospital.
Gostling, William Ayton, B.Sc., University College.
Green, Charles David, St. Thomas's Hospital.
Gross, Charles, Guy's Hospital.
Irvin, Frederic David, University College.
Jones, Frederick William Caton, St. Bartholomew's Hospital.
Jones, John Hervey, Owens College and Manchester Royal Infirmary.
Lewers, Arthur Hamilton Nicholson, University College.
Mumby, Langton Philip, Westminster Hospital.
Penrose, Francis George, University College.
Powell, John Joseph, University College.
Prideaux, Frances Helen, London School of Medicine for Women and Royal Free Hospital.
Purslow, Charles Edwin, Birmingham School of Medicine.
Reynolds, Ernest Septimus, Owens College and Manchester Royal Infirmary.
Rouse, Rolla Edward, St. Thomas's Hospital.
Rushworth, Frank, St. Bartholomew's Hospital.
Spencer, Herbert Ritchie, University College.
Thorburn, William, B.Sc., Owens College and Manchester Royal Infirmary.
Turner, Alfred Jefferis, University College.
Vince, John Foster, Queen's College and Hospital, Birmingham.
Womack, Frederick, B.Sc., St. Bartholomew's Hospital.
Woolbert, Henry Robert, University College.

Digitized by Google

SECOND DIVISION.

Adie, Joseph Rosamond, University College.
Anderson Daniel Elie, B.A., B.Sc., University College.
Beevor, Hugh Reeve, King's College.
Bernard, Letitia Caroline, London School of Medicine for Women and Royal Free Hospital.
Bigger, Samuel Ferguson, University College.
Brown, James Grierson, Liverpool Royal Infirmary.
Cooper, George Frederick, St. Thomas's Hospital.
Dobson, Joseph, Leeds School of Medicine.
Evans, William Arnold, Owens College and Manchester Royal Infirmary.
Floyer, William Wadham, Guy's Hospital.
Lynam, Robert Garner, King's College.
Marriner, William Herbert Lister, St. Thomas's Hospital.
Parkinson, Charles Joseph, Owens College and Manchester Royal Infirmary.
Thomas, John Raglan, St. Bartholomew's Hospital.
Thomson, Theodore, Universities of Aberdeen and Edinburgh.

APOTHECARIES' HALL. — The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Nov. 13th:—

Darlington, Alfred Naylor, Queen's College, Birmingham.
Davis, David, King's College.
Dickinson, Joseph Jewitt, Cambridge and London Hospital.
Edginton, Alfred Dudley, St. Bartholomew's Hospital.
Foster, Albert Ernest, Leeds School of Medicine.
Humphry, Ernest, St. Bartholomew's Hospital.

THE sum of £500 has been bequeathed to the Walsall Cottage Hospital by the late Mr. Edmund Burke.

ROYAL COLLEGE OF SURGEONS.—Mr. William Scovell Savory, F.R.S., Vice-President of the College, will deliver the annual "Bradshawe Lecture," on Thursday, the 4th proximo.

THE Corporation of London have thrown open to the public, for the purposes of recreation, the disused burial-ground known as Bunhill-fields, City-road.

MEDICAL MAYOR.—The following name was inadvertently omitted from the list given in THE LANCET of last week: J. E. Brooks, L.R.C.P.Ed., M.R.C.S., Ludlow.

DR. JONATHAN ATKINSON HARRISON, Hazlewood, Haslingden, has been placed on the Commission of the Peace for the county of Lancaster.

BEQUESTS.—The late Mr. James Lindsay has bequeathed £500 to the Belfast Royal Hospital, £500 to the Society for Providing Nurses for the Sick Poor, and £500 to the Belfast Charitable Society.

SAMUEL HOLMES, an unqualified assistant, who was tried at York on Wednesday for having caused, by improper treatment, the death of a woman whom he attended in her confinement, has been acquitted.

ON the 15th inst., Mr. Rowe, a student of St. Thomas's Hospital, fell dead in the football field. Mr. Rowe was twenty-three years of age, and one of the senior students.

DEATH FROM FRIGHT.—A child has recently died at Rye from shock to the nervous system, caused by fright at seeing a boy wearing a mask. She lost her reason the first day after the occurrence.

THE UNIVERSITY OF ADELAIDE.—The Council of this University are inviting applications for a Professorship of Anatomy. Full particulars are to be obtained of the Agent-General for South Australia, Sir Arthur Blyth, K.C.M.G., 8, Victoria Chambers, Westminster.

ON the 17th inst. the Queen attended the funeral of Willie Blair, "Her Majesty's Highland fiddler," who died last week at the venerable age of ninety years. The remains were interred at the churchyard of Crathie, where a monument will be raised by command of the Queen.

THE VACCINATION ACTS.—Sir Charles Dilke, in answer to a memorial from Leicester as to the prosecution of 3000 defaulters under the Compulsory Vaccination Acts, has replied to the effect that he must decline to receive a deputation on the subject. He adds that the law must be carried out and that he cannot interfere with its enforcement.

CAMBRIDGE PHILOSOPHICAL SOCIETY.—The following elections were made at the annual meeting of the Society on Monday last: Professor Michael Foster, president; Professor Stokes, Lord Rayleigh, and Prof. Liveing, vice-presidents; Mr. J. W. Clark (Trinity), treasurer; Mr. Coutts Trotter (Trinity), Mr. Glazbrook (Trinity) and Mr. S. H. Vines (Christ's), secretaries.

PENNY MEALS.—The Exhibition in Humphreys' Hall, Knightsbridge, under the auspices of the Bread Reform League, will be opened to-day (Saturday). An evening *fête* will be held on Wednesday, the 26th inst., in order to raise a fund for providing wholesome and satisfying breakfasts and dinners for poor school children in London at the cost of one penny per meal.

SUICIDE OF A SURGEON.—An inquest was held on the 15th inst., at Cheltenham, on the body of Mr. W. A. Moseley, late resident surgeon at the branch dispensary in connexion with the Cheltenham General Hospital, who died on the previous day from the effects of a dose of prussic acid. A verdict of suicide whilst in a state of unsound mind was returned. Singularly enough, Mr. Moseley's predecessor met with his death in a similar way in the same house two years ago.

QUEEN'S COLLEGE, CORK.—The following scholarships and exhibitions have been awarded in the Faculty of Medicine:—Fourth year: Physiology, Anatomy, and Surgery, James Bradley; Medicine, Midwifery, and Medical Jurisprudence, Cornelius Bradley; Exhibitioners, Daniel J. Lane and William A. Whitelegge. Third year: John Ambrose Keogh (first), and J. R. T. Connor (second); Exhibitioner, Charles R. Leader. Second year: Edward R. Hennessy (first), and Robert J. Duffin (second).

UNIVERSITY OF CAMBRIDGE.—The number of freshmen intending to study medicine who have this term entered at Cambridge University is 111. A few more may have to be added in December after the result of the previous examination is known; this examination serving for many as the examination preliminary to registration by the General Medical Council. The freshmen are variously distributed over all the colleges and public hostels, one college only excepted. A small number are entered as non-collegiate students.

SPEAKING at Devonport on the 19th inst., Admiral Sir W. Houston Stewart, commanding the western district, said that his prediction that the repeal of the compulsory clauses of the Contagious Diseases Act would be a disastrous step had been more than justified. On board the flagship the number of cases had doubled, and out of a draft of fifteen men sent on board a ship under orders for China, thirteen had to be sent back. He regretted that his position as Commander-in-Chief prevented him from commenting as he would like on this false step.

ANTHROPOLOGICAL INSTITUTE.—At the meeting on the 11th inst., Mr. Francis Galton described the object, method, and appliances of the late Anthropometric Laboratory at the International Health Exhibition, reserving the statistical results, which were not yet fully worked out, for another occasion. The result showed that 9344 persons passed through the Laboratory, each of them being measured in seventeen distinct particulars for the sum of 3*d.* in a compartment only six feet wide and thirty-six feet long. Mr. H. O. Forbes read a paper on the People of the Island of Barn.

ROYAL SOCIETY MEDALS.—The Council of the Royal Society have made the following award of medals:—The Copley Medal to Professor Carl Ludwig of Leipzic, foreign member of the Royal Society, for his investigations in physiology and the great services he has rendered to physiological science; the Rumford Medal to Professor Tobias Robertus Thalé of Upsala, for his spectroscopic researches; a Royal Medal to Professor G. H. Darwin, F.R.S., for his mathematical investigations on the rigidity of the earth, and on tides; a Royal Medal to Professor Daniel Oliver, F.R.S., for his investigations in the classification of plants and for the great services which he has rendered to taxonomic botany; the Davy Medal to Prof. A. W. H. Kolbe of Leipzig, foreign member of the Royal Society, for his researches in the isomerism of alcohols.

WYCOMBE COTTAGE HOSPITAL.—At the recent annual meeting of the supporters of this institution it was stated that during the year ending Sept. 30th 112 patients had been admitted. Towards the enlargement of the men's accident ward and the cost of furnishing £320 had been contributed, and after paying for everything a balance of £60 remained in the treasurer's hands. Although the charges for maintenance had increased on account of the larger number of patients, the financial condition of the hostpial had been satisfactory.

TYPHUS FEVER AT CHORLTON.—At the weekly meeting of the Chorlton Board of Guardians on the 14th inst., it was stated that with the exception of ten or twelve beds the hospital at Monsall was full. Fresh cases of typhus had occurred during the week, and the condition of the houses in the district where the fever most prevailed was described as disgraceful. It was suggested that a deputation from the guardians should be appointed to see the Health Committee on the subject; but as it was understood that the Corporation were taking some steps in the matter, the motion was not pressed.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BACK, HERBERT HATFIELD, M.B.Lond., has been appointed Medical Officer of Health for the Rural Sanitary District of the Blofield Union, vice F. Cufande, resigned.

BLUETT, GEORGE MALLACK, M.R.C.S., has been appointed Assistant House-Surgeon to the London Temperance Hospital, Hampstead-road, N.W.

CHADWICK, ALFRED, M.D.Brux., L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for the Heap District of the Bury Union, vice Worsley.

CUFANDE, FRANK, M.R.C.S., has been appointed Medical Officer for the Acle District of the Blofield Union, vice W. H. Cufande, deceased.

EAST, C. H., L.S.A.Lond., has been appointed Assistant House-Physician to King's College Hospital.

GILPIN, GEORGE LUCK, M.R.C.S., has been appointed Assistant Medical Officer and Dispenser for the Central London Sick Asylum District.

HASELL, E. S., L.S.A.Lond., has been appointed Physician-Accoucheur's Assistant to King's College Hospital.

HILL, M., M.D., has been appointed Honorary Physician to the Bootle Borough Hospital, vice G. C. Walker, M.D., resigned.

HODGES, HERBERT CHAMNEY, L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer for the Fourth District of the Hertford Union, vice H. B. Hodges.

HODGSON, G. G., M.R.C.S., L.S.A.Lond., has been appointed Physician's Assistant to King's College Hospital.

HOUGHTON, LAMBERT, L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer of Health for the Amersham Rural Sanitary District, vice Hosegood, whose appointment has expired.

HUGHES, EDGAR A., M.R.C.S., L.S.A.Lond., has been appointed Assistant House-Accoucheur to King's College Hospital.

HUTCHINSON, S. J., M.R.C.S., L.D.S., has been appointed Lecturer on Dental Surgery and Pathology at the London School of Dental Surgery, vice Alfred Coleman, F.R.C.S., L.D.S., L.R.C.P., resigned.

JACOMB-HOOD, C., M.R.C.S., L.S.A.Lond., has been appointed House-Surgeon to King's College Hospital.

JONES, R. NELSON, L.R.C.P.Lond., M.R.C.S., has been appointed House-Surgeon to the Swansea Hospital, vice W. Carr Humphreys, M.R.C.S. &c., resigned.

LANE, ALEXANDER, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Presteigne District of the Knighton Union, vice Harding.

MCGEAGH, JAMES PAUL, M.D., M.Ch.Q.U.I., has been appointed Resident Medical Superintendent to the West Derby Union Infirmary, Mill-road, Everton, Liverpool.

MACLEHOSE, NORMAN M., M.B., C.M., has been appointed Resident Medical Officer to the Sick Children's Hospital, Glasgow, vice Mr. W. S. H. Walker, whose term of office has expired.

PENNY, FRANCIS, M.R.C.S., L.S.A.Lond., has been appointed House-Surgeon to King's College Hospital.

PRIESTLEY, JOSEPH, B.A., M.B., M.R.C.S., has been appointed Resident Clinical Assistant to the Hospital for Consumption and Diseases of the Chest, Brompton.

NEWSHOLME, ARTHUR, M.D.Lond., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer of Health for the Clapham District.

REID, FRANK, L.R.C.P.Ed., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Sixth District of St. Saviour's Union.

ROBINSON, HUGH SHAFTER, M.R.C.S., L.R.C.P.Ed., has been elected an Honorary Surgeon to the Monkwearmouth Dispensary and Accident Home.

ROSE, J., M.R.C.S. &c., has been appointed Honorary Ophthalm Surgeon to the Bootle Borough Hospital.

RUNDLE, EDMUND, L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer for the Sithney District of the Helston Union.

RUSSELL, A. W., M.B., C.M.Aber., has been appointed Medical Superintendent to the Western Infirmary, Glasgow.

SLATER, DRUCE J., M.B.Lond., M.R.C.S., has been appointed Resident Clinical Assistant to the Hospital for Consumption and Diseases of the Chest, Brompton.

TRIMMER, H. BEESLEY, M.D. St. And., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Third District of St. Neots Union, vice Walker.

TUKE, J. BATTY, jun., has been appointed Deputy Medical Superintendent of the Saughton Hall Institution for the Cure and Care of the Insane.

TURNER, N. H., M.R.C.S., has been appointed House-Surgeon to King's College Hospital.

WALKER, G. C., M.D. &c., has been appointed Honorary Consulting Physician to the Bootle Borough Hospital.

WILLIAMSON, J., M.B., C.M.Ed., has been appointed Junior Resident Medical Officer to the Great Northern Central Hospital, Caledonian-road, London, N.

Births, Marriages, and Deaths.

BIRTHS.

DOUGLAS.—At 1, Marshall-place, Perth, N.B., the wife of T. Kennedy Douglas, M.B., C.M., &c. (late of Tapanui, New Zealand), of a daughter.

GILLESPIE.—On the 12th inst., at Upper Belgrave-road, Clifton, the wife of W. H. Gillespie, L.R.C.S.I., L.K.Q.C.P.I., of Castle Cary, Somerset, of a son.

HEAD.—On the 15th inst., at Morton House, Weymouth, the wife of Philip Alexander Dewar Head, M.R.C.S., of a son.

HUTCHINSON.—On the 9th inst., at Neasden, the wife of S. J. Hutchinson, L.D.S., M.R.C.S., of Brook-street, W., and The Grange, Neasden, N.W., of a daughter.

RUTTLEDGE.—On the 24th ult., at Jaunpur, N.W.P. India, the wife of Surgeon-Major E. B. Ruttledge, Bengal Medical Service, of a son.

STEIN.—On the 12th inst., at Grove House, Warsop, Nottinghamshire, the wife of Charles Guthrie Stein, M.R.C.S.E., & M.B., C.M.Ed., of a daughter.

MARRIAGES.

BAILEY—ASPINALL.—On the 19th inst., at the Parish Church, Lee, by the Rev. E. Snowdon Smith, Rector of St. Mary's, Waverтree (cousin of the bride), assisted by the Rev. W. B. Bucke, Vicar of Holy Trinity, Lee, Henry Frederick Bailey, M.R.C.S. &c., of The Hollies, Lee-terrace, Blackheath, to Charlotte Hannah (Lota), only daughter of J. Aspinall, of Blackheath.

FORD—WAINWRIGHT.—On the 12th inst., at St. Jude's, Southsea, Richard William Ford, Army Medical Department, youngest son of R. W. Ford, Esq., of Portsmouth, and the Manor House, Wymering, to Mary Augusta, youngest daughter of the late Rear-Admiral J. F. B. Wainwright.

FRASER—RUSSELL.—On the 12th inst., at Skelmorlie Church, N.B., James Fraser, M.D., Deputy Surgeon-General, to Annie Jane, daughter of the late John Russell, of Kew-terrace, Glasgow.

DEATHS.

BLASSON.—On the 10th inst., at Epsom, suddenly, Thomas Hereward, the beloved eldest son of Thomas and Louie Blasson, of Billingboro', deeply lamented, aged 11 years. Friends will kindly receive this intimation.

BOWMAN.—On the 13th inst., at Windsor-terrace, Newcastle-upon-Tyne, Hugh Torrington Bowman, M.D., aged 40.

CARROLL.—On the 8th inst., at his residence, Lady-lane, Waterford, William Carroll, M.D., aged 81.

JONES.—On the 3rd inst., at Llanfyllin, North Wales, John Jones, L.S.A.Lond., in his 65th year.

LANGSTAFF.—On the 9th inst., at Havre, France, Charles Langstaff, M.D., of Bassett, near Southampton, aged 51.

MOSELEY.—On the 14th inst., at Cheltenham, William Arthur Moseley, M.D., fourth son of E. C. Moseley, Esq., of Nassau, Bahamas, aged 32.

RAINEY.—On the 16th inst., George Rainey, M.R.C.S., of St. Thomas's Hospital and Brixton, in his 84th year.

SALL.—On the 15th inst., at Munster-terrace, Fulham, William Sall, M.D., Deputy Inspector of Army Hospitals and Medical Officer to H.M. Female Convict Prison at Fulham, aged 73.

SEWELL.—On the 10th inst., at Guy's Hospital, from phlegmonous inflammation about the larynx, Joseph James Sewell, M.R.C.S. and L.R.C.P. Edin., only son of the late Mr. Joseph Sewell, Halstead, Essex.

WILSON.—On the 13th inst., at Lonsdale, Newton Abbot, suddenly, John Wilson, Surgeon-General, Madras Army (Retired), aged 66.

WRIGHT.—On the 17th inst., at St. Margaret's-terrace, Cheltenham, Dr. Thomas Wright, F.R.S., aged 75.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

Monday, November 24.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10½ A.M. each day, and at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.
ST. MARK'S HOSPITAL.—Operations, 2 P.M., and on Tuesdays at the same hour.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M
LONDON HOSPITAL MEDICAL COLLEGE.—3 P.M. Mr. Jonathan Hutchinson: The Art of Note-taking and other Matters.
MEDICAL SOCIETY OF LONDON.—8.30 P.M. Discussion on Anæsthetics. Paper by Mr. Woodhouse Braine. The discussion to be opened by Mr. G. H. Bailey.

Tuesday, November 25.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 P.M., and Thursdays at 2 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ANTHROPOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND.—8 P.M. Dr. J. G. Garson: Exhibition of a Prehistoric Skull from the Island of Antiparos.—Dr. W. H. Coffin: Note on the Abnormal Dentition of a Hairy Boy from Russia.—Miss A. W. Buckland: Fact Suggestive of Prehistoric Intercourse between East and West.—Mr. Horatio Hale: Some Doubtful or Intermediate Articulations.—Mrs. Erminie A. Smith: Remarks on the Customs and Language of the Iroquois.
ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Mr. Henry Morris: A Successful Case of Lumbar Nephrectomy for Renal Calculus.

Wednesday, November 26.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.—Ophthalmic Operations on Tuesdays and Thursdays, at 1.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1½ P.M.—Skin Department: 9.30 A.M., on Tuesdays and Fridays.
ST. THOMAS'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.
LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.
GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations 2½ P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour.—Skin Department: 1.45 P.M., and on Saturday at 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M.
LONDON HOSPITAL MEDICAL COLLEGE.—3 P.M. Mr. Jonathan Hutchinson: The Surgery of the Receiving Room.
HUNTERIAN SOCIETY.—8 P.M. Dr. Goodhart: Water on the Brain.—Dr. Herman: The Number of Persons who Suffer from Headaches.—Mr. Charters J. Symonds: The Spontaneous Disappearance of Nævi.

Thursday, November 27.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—1½ P.M. Surgical Consultations.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

VACCINATION FROM CALF LYMPH.

To the Editor of THE LANCET.

SIR,—In his address before the Islington Medical Society, Mr. Shirley Murphy stated (THE LANCET, May 31st, 1884) that it was too soon as yet to speak positively of the protection afforded by vaccination with the calf lymph of the Government Institution in Lambs-conduit-street. The following case shows, I think, as far as any isolated case can do, that it is similar in this respect to human lymph.

One son out of a family of eight was attacked with small-pox, which, when first seen, on Oct. 2nd, had already proved fatal, the rash being then fully developed and thickly covering the body. The boy was nursed by his mother, who had a baby at the breast, which was therefore constantly in the room, but had never been vaccinated. On Oct. 3rd the baby was vaccinated with calf lymph, obtained from the Government Institution. By the 18th only one place had taken; but the child was very fretful, and a papular rash appeared sparingly over the body and face, developing into the characteristic umbilicated vesicles of small-pox, which were, however, very small, and died away almost before coming pustular, the total duration being about a week.

There can, I think, be no doubt that this was an extremely mild attack of small-pox; for the rash did not appear simultaneously with the vaccination vesicle, but several days later, and fresh spots kept coming out for two or three days. The probabilities are strong that its course was so modified by the vaccination; for most authorities agree that the prognosis in infancy is extremely unfavourable, the mortality, according to Curschmann (Ziemssen's Cyclopædia of Medicine), being as high as 58 per cent. for children under ten. Of the remaining six children in this family two had never been vaccinated, and had had small-pox; another unvaccinated child had died some years ago from that disease; while the remaining four, who had been vaccinated as infants, all escaped, though they had been twice exposed to the infection, showing a great tendency in the family to contract the disease unless protected by vaccination.—I am, Sir, yours truly,

Nov. 10th, 1884. R. W. GREENISH, F.R.C.S.

Mr. Blaney.—The Rev. Alex. J. D. D'Orsey, Prince's-square, W., or Dr. Altschul, Old Bond-street, W., might be applied to.

Mr. Gerrard.—Next week.

"THE LIBRARY OF THE COLLEGE OF SURGEONS."

To the Editor of THE LANCET.

SIR,—I should like to endorse the sentiments contained in the letter of "A Member" in your last issue respecting the closure of the College of Surgeons library. But I would extend my complaint much further, and ask why not only the library, but the museum also, should be closed at 4 P.M. on ordinary days and earlier on Saturdays? There must be many juniors, like myself, in London engaged either in study, literary work, or tuition, who are practically debarred from making use of these institutions at all by their absurdly prohibitive regulations in respect of closing. Most men have settled occupation during the daytime, which keeps them fixtures in some particular locality; the evening alone remains to them to engage in literary research, or to take their pupils over such excellent dissections as may be found in the College of Surgeons Museum.—I am, Sir, yours faithfully,

Austin Friars, E.C., Nov. 17th, 1884. KENNETH MILLICAN.

A NEW-BORN INFANT OF EXTRAORDINARY SIZE.

To the Editor of THE LANCET.

SIR,—Yesterday I attended a woman who was delivered of a male child of extraordinary size, weighing 20 lb. 2 oz, and measuring twenty-three inches in length, and fourteen inches and a half round the chest at the level of the nipples; it was well developed and quite healthy. These particulars were verified in the presence of two medical gentlemen I asked to be kind enough to check my statements, as they have such an incredible appearance.—I am, Sir, yours truly,

Crewe, Nov. 13th, 1884. GEORGE EDDOWES.

MICROSCOPIC OBJECTIVES.

To the Editor of THE LANCET.

SIR,—As your correspondent, "A Student," appealed to me by name in your issue of the 8th inst. I willingly reply, but, with your permission, I must enter into some detail, as the subject is not always well understood even by those who have had some experience in microscopy.

Of course, the prime essential in any glass is the quality termed "definition," which means that clear lines or contours should be sharply rendered, whilst the whole image should also be presented free from distortion. This depends on the perfection of the corrections. If a flat object, as a page of print, is viewed through a single lens, only the central part will be seen truthfully magnified and distinct, all the marginal portions being blurred and distorted, while any straight lines near the edge will be strongly curved outward, and bordered with fringes of colour. This arises from spherical and chromatic aberrations in the glass, and these are corrected by the successive lenses required for the due amplification, some of which are of flint and others of crown-glass. These have different dispersive power, and they are so carefully adjusted that the error of the one exactly neutralises that of the other. The compound lens, which we call an objective, is thus enabled to give a flat field of view, or one in which the object is focused all over and without any spurious colour. The finely ruled lines of a stage micrometer should appear equally distinct and straight to the edge of the field, while such objects as a balsam-mounted tracheal vessel of insects should show no colour in its closely set rings. A severer test of perfectness of correction is the using a high eyepiece. A very inferior foreign glass may, under a low ocular, seem to be nearly as good as a choice one, but put on an ocular one or two numbers higher, and it will break down into mist, while the definition of the better glass remains but little impaired. With fine glasses the second, or B, eyepiece may be habitually employed with advantage, while good work can be done under oculars up to E, thus giving a wide range of powers with only two or three objectives.

When several objectives of the same power are offered at different prices, as your correspondent remarks, it will be observed that the "angle of aperture," as it is called, varies accordingly. This expresses in degrees (360 to the circle) the diameter of the cone of rays which the front lens can take in. The wider this is the more difficult it becomes to render the corrections perfect, hence the price rises in proportion. But the enlargement of aperture only improves the glass for certain purposes, while it may even deteriorate it for general use. Every degree added increases the "resolving power" (the corrections being equally well made), but this is only needed for a special class of objects. It is not synonymous with definition in the broader sense, or only represents one restricted phase of it—namely, the displaying delicate surface-markings, as on the more difficult diatoms. It is the almost exclusive use of these as tests which has led our opticians to enlarge the angular aperture at any sacrifice. One serious drawback is the "shallowness" of view which it causes. It is true that in theory a glass should only focus sharply one single true plane, but such a glass would be practically useless, as very few objects are absolutely flat. The artificial eye, like the real one, should have more or less adaptability for distance; should show fairly a certain depth of an object, or it cannot give any useful view of it. For example, let us examine an injection, or dry stellated leaf, with a half-inch of 30°, and we may find that only bits here and there, which happen to be in precisely the same plane, will be focused, while all the rest is in fog. If we replace this half-inch by another of only half its angle, or 40°, the whole will be usefully seen in fair perspective view. At the same time no one part will show with the same exquisite sharpness as when actually focused before. Hence for determining difficult and delicate points of structure, glasses of high angle become invaluable on occasion, even to the histologist, though for general use on the ordinary run of objects they are inferior to those of only moderate aperture. In fact, the lower the angle the greater is the penetrative power, so that for very uneven objects the lowest angled glass should give the most complete view. But the dimness of the object, from the lesser amount of light received into the glass, imposes a limit in this direction and compels us to a compromise. An example will illustrate this. Wray makes no less than three one-inch of the same power, and only differing in their angles of aperture, which are respectively 16°, 22°, and 27°. By repeated close scrutiny I have found that all three are perfectly corrected, so that, in its own way, the first is as fine a glass as the last, which is double the price. It will give an even better view of rounded and uneven natural objects, as seeds, micro-fungi, insect eggs, foraminifera, &c., of which the last glass will have a far less comprehensive grasp. On the other hand, the latter would show minute structural details, especially of surface, more clearly and sharply defined. Were it not for the cost, a microscopist might usefully have all the three one-inch, though their power is alike, one displaying best certain objects, another certain others; but where only one can be had the medium angle is the most generally useful. Thus for the histologist the one-inch of 23° and quarter-inch of 90° would be preferable to either the more expensive ones or those of 16° and 70°, though I must add that the latter of Wray's are fully adequate for the student, and will be found far superior to foreign glasses at the same price. They are so perfectly corrected as to work well under E ocular.

Having thus endeavoured to give a practical, and I trust intelligible, reply to your correspondent's query, I must pause. I might have added some impartial data from my experience of various glasses and makers, which I should be willing to do at a future time, if desired.

I am, Sir, yours obediently,

FREDERICK W. GRIFFIN, Ph.D.

Bristol School of Chemistry, Nov. 10th, 1884.

THE following lines, from an esteemed Prelate, will be read with gratification by the profession, not only for their own sake, but for the fact that they proceed from one of another calling, whose wise estimate of medical heroism and kindness will tend to correct narrower views which are held too often by those of whom better things might have been expected.

UNTITLED HEROISM.

PART I.

Lay him in his quiet grave,
With no marble token;
There his deeds so simply brave
No words need be spoken.

Such man need no epitaph,
Nor the sculptured glory;
Flowers are best, for deaths like theirs
Are sweet as Nature's story.

You think that doctors have no hearts,
So passionless their features
As calm they stand with knife in hand
Over living creatures!

But true compassion grows in man
When pity's soft emotion
Becomes a principle of life,
As tide within the ocean.

And he whose nerve is well controll'd,
Whose hand is strong and steady,
May, more than sobbing, frighten'd girl,
Have pity, aye and ready.

Those calm, clear eyes will quickly see,
But wince not at the danger;
Those quick, firm hands will skilful work,
Unjudging, for a stranger.

PART II.

A little child was brought in here,
The death-grasp round its throat;
The poison fast was wasting there
Its filmy, murd'rous coat.

One moment more! Another way
Is made for the deadly stream;
Tender and merciful in touch,
The knife, with its rapid gleam!

But slow to move is the loathsome thing.
There is danger in delay!
But firm, brave lips are pressing there,
To draw the death away.

The peril he knows; but he bravely drinks
The poison draught he filled,
To give another day of life
To the little stranger child!

No ardour of battle urges him,
No fame or title's won,
No loud applause, no trumpet blows;
But calmly the deed is done.

And now he is dead; for the poison flood
Hath drained his life away.
And could a hero in battle
Do more than this, I pray!

We shall build our solid, sumptuous tombs
For those who our foes have slain;
But no marble tells of life laid down
For our people in death and pain.

Yet, leave him in his mossy grave,
And let us our home-way take;
But hold henceforth a doctor's work
More high for the dead man's sake.

And I, who have had given me
Christ's gospel in charge to preach,
Hold nobler for the gospel-lived
More eloquent than speech.

Dr. Percy Boulton.—We are sorry to be obliged, from want of space, to omit from our columns many communications which we would, if we had room, gladly publish.

A. B.—Such a mode of advertising would be decidedly unprofessional.

INTERMITTENT IRITIS.

To the Editor of THE LANCET.

SIR,—The following case may interest your readers, and I shall be glad of any hints as to treatment and prophylaxis.

A. B——, aged forty, a tall, well-developed man, of temperate habits, has frequent attacks of gouty iritis. He is a retired military man, and amuses himself by composing music and chess, and it is noticed that an attack always follows a chess match. The attacks at first occurred at intervals of two years. During the past year he has had three attacks in February and April when at Hyères, and now in October, each attack lasts about three weeks. They at first yielded to half-drachm doses of iodide of potassium, bicarbonate of potash, and colchicum. Now, one drachm doses of iodide of potassium do not control them, although the soft palate and pharynx are quite turgescent, except in rendering the pain less acute. The pupil is always kept dilated with atropine, the diet moderate, and a small quantity of whisky allowed. Excessive nocturnal pain is treated with one grain of opium.

I am, Sir, yours truly,

Nov. 11th, 1884. VIATOR.

THE COST OF A SMALL-POX EPIDEMIC.

By accident an error crept into the calculations in our sub-leader of the 15th inst. The total actual cost of 2040 cases of small-pox to the State of Illinois amounted to over $281,000 00 (or £81,000 dollars), and the constructive loss to over $3,339,600 00 (or 3,339,600 dollars), and the expenses to the State during the period of the epidemic to close upon $1,404,000 00 (or 4,404,000 dollars).

"IRRITATION OF THE SKIN FOLLOWING THE APPLICATION OF VASELINE AS A SURGICAL DRESSING."

To the Editor of THE LANCET.

SIR,—In your issue of Nov. 8th you publish a communication from A. W. Mayo Robson, F.R.C.S., of the Leeds General Infirmary, entitled "Irritation of the Skin following the Application of Vaseline as a Surgical Dressing." Immediately after reading the same, we sent Mr. Robson the following letter:—

"Nov. 12th, 1884.

"Dear Sir,—The last issue of THE LANCET (Nov. 8th) contains a communication from you in which you state that 'severe inflammation of the skin has been set up by the application of "vaseline" as an ointment, and you go on to give several cases in which you have observed this effect.' As the word 'vaseline' is the registered trade mark of this company and can be applied only to goods of our manufacture, your statement is a grave injury to us and a reflection upon the quality of vaseline, which has received the unanimous commendation of the highest medical, chemical, pharmaceutical, and scientific authorities during the past twelve years, and it becomes a matter of the greatest importance to determine whether you really used vaseline or some imitation fraudulently sold under that name. Will you be good enough therefore to more particularly describe the article you used, and say, where it was procured?

"Awaiting your reply, we are, very truly yours,

"CHESEBROUGH MANUFACTURING COMPANY."

To A. W. Mayo Robson, F.R.C.S., Leeds General Infirmary."

To this we have his reply:—

"Hillary-place, Leeds, Nov. 17th, 1884.

"Dear Sirs,—The vaseline used at the infirmary may be manufactured by someone else, but you can easily get the information you require through Mr. Whiteley, the dispenser, or through Mr. Blair, the manager. The vaseline I used in private was made by yourselves, or at all events was sent out with your name affixed. I am sorry if injury to your trade should occur by my paper, but my experience is not solitary. I fancy some skins will be irritated with vaseline, however pure.

"Yours faithfully,

"A. W. MAYO ROBSON."

During last June our representative visited the Leeds General Infirmary and ascertained that they were using a common grease, which the dispenser called "mineral fat," and which in no way resembled vaseline. As price seemed to be the primary object, and not quality, he suggested a trial of our ordinary red, or veterinary, vaseline, which we sell for use on animals only. Since then we have supplied the hospital with three lots of this article—viz., June 27th, 50 lb.; July 19th, 200 lb.; Sept. 15th, 200 lb.; and we are to-day in receipt of a further order for 200 lb.

Mr. Robson states in his communication that he used "vaseline of a greenish colour." This is not the colour of vaseline, and leads us to suppose that he employed the mineral fat in the cases referred to. In any event, we have supplied the hospital only with our inferior grade, made for use on beasts; and no one acquainted with the difference between the two could expect the same beneficial results from the application of this article to the delicate skins of human beings as from the application of the refined product made especially for the purpose. But the fact that the veterinary has been used so long in such quantity by so prominent an institution as the Leeds Infirmary speaks well for the quality even of that article. As for Mr. Robson's opinion that he fancies that "some skins will be irritated with vaseline, however pure," we think we can safely leave it to the profession to decide whether, on his own showing, he has had sufficient experience with the pure vaseline to justify his statement.

We rely upon your spirit of fair play to give this letter an equally prominent position in your journal which you accorded to Mr. Robson's communication.—We are, Sir, yours faithfully,

CHESEBROUGH MANUFACTURING COMPANY.

Holborn-viaduct, London, E.C., Nov. 17th, 1884.

To the Editor of THE LANCET.

SIR,—In reference to the experiences of Mr. A. W. Mayo Robson and Dr. H. Stowers on the above subject, perhaps the following case may be of interest.

I had been treating a female patient, aged about forty years, who was suffering from lupus exedens of the nose and left cheek. After the more vigorous treatment, I with decided benefit had recourse to a mild mercurial oxide ointment, the body of which was composed of vaseline and olive oil in equal parts, with sufficient white wax to give it the proper consistency. Not having some of this ointment with me, I sent the patient some vaseline *pro tem.* The next morning when I called I found her suffering from a considerable amount of inflammation of the skin around the nose. After a few days I returned to the use of the previous ointment, which suited admirably. Subsequently I again used the vaseline, to try its effect, when it produced the "dermatitis" as before, and I dared not try it again.

In this case it is apparent that although the patient could not tolerate vaseline alone, yet when used in combination, or diluted with other emollients, it had lost its irritating effect.—Yours faithfully,

J. MICHAEL NICHOLLS, L.R.C.P. Lond., &c.

St. Ives, Cornwall, Nov. 17th, 1884.

Mr. E. F. Yeates.—Heads of tapeworms can be well displayed and preserved in glycerine or in glycerine jelly, but probably Dean's preservative gelatine is the best medium. Whatever medium is employed care must be taken to soak the specimen in it for several days before finally mounting. Great improvements have of late been introduced, but for the beginner Davies' little book, price 2*s.* 6*d.*, on the "Preparation and Mounting Microscopic Objects," is perhaps the best. Mr. Dean's preservative fluid is described in Dr. Beale's book, "How to Work with the Microscope," fifth edition, p. 67.

Mr. D. Gulland.—It is undoubtedly injurious.

THE WANT OF PRACTICAL TEACHING IN MIDWIFERY.

To the Editor of THE LANCET.

SIR,—My attention has been drawn to the statement made by Dr. Haughton, on Oct. 10th, in the General Council of Medical Education, respecting the incomplete manner in which newly qualified men were turned out by the medical schools of Dublin fifteen or sixteen years ago with regard to their practical knowledge of midwifery. I am very much afraid that this statement is just as applicable to the present time as to the past—at least, so far as my experience leads me. I have met with men possessing the M.D. of Dublin, also the L.K.Q.C.P. and the L.R.C.S., who have practically no knowledge whatever of midwifery. In my own practice, within the last twelve months, I have been called in to assist two of them in ordinary cases of version, and in neither case did they know how to proceed. The first of the two cases was a very simple one, and was over in twenty minutes. In the second case the arm was protruding, and the highly qualified man, with honours, had not even digitally examined, but was satisfied, by *looking*, that he could do nothing. I have also had men from the Irish schools acting for me as locum tenens, and when I have afterwards heard of the cases they attended, it has been that the midwife did the work for them, one (a L.K.Q.C.P.) leaving the afterbirth. Surely, these are not the class of men to do credit to the profession. For my part, I prefer a man who has either served an apprenticeship or been an unqualified assistant before taking his degrees than one who is all theory and no practice. The former has learnt while unqualified that, for his own reputation, he must be careful; but the latter go out upon the world, armed with their wonderful diplomas, to kill or cure—and, sad to say, it is the former in very many instances—before the owners of such diplomas have learned their practical work. Would it not, in fairness to the future qualified men, be more to their interest to insist upon them actually conducting fifty cases, of which twenty should be under the direction of some medical man. Surely, twenty cases, as at present required, are not enough to give a man an insight into the hundred and one different things which at any moment crop up in actual practice. Until our universities and medical schools can see their way to teach midwifery differently than by lectures, I am afraid the qualified men of the future will not shine as obstetricians.

I am, Sir, yours truly,

Nov. 10th, 1884. MEMBER BRIT. MED. ASSOC.

Constant Reader.—We have already noticed the offensive announcement, and we believe the attention of the Colleges whose diplomas are thus disgraced has been called to the matter.

"M.B. PASS EXAMINATION, UNIVERSITY OF LONDON."

To the Editor of THE LANCET.

SIR,—A gentleman who read my letter in your last issue has just pointed out to me that "unilateral hæmatokolpos" is mentioned in Quain's Dictionary under the head "Vagina." Allow me, therefore, to correct the inaccuracy.

As you have allowed a correspondent to ask whether that question could be "the crux of a dyspeptic examiner," you may perhaps permit me to call attention to another paper at the same examination. The following is one of the six prescriptions set by the examiners in medicine, and required to be "written in Latin, without abbreviations, with directions for administration":—"Order mustard poultices to be applied to the calves of the legs for a given time." I should like to ask these gentlemen, who are hospital physicians, whether they have ever considered the classical Latin in which they would direct a nurse, or even a dresser or house-surgeon, to have sinapisms applied to a patient's calves? If so, have they ever, either in hospital or private practice, ordered a nurse or other attendant to do so in Latin; and, in that case, whether their directions were understood and carried out?

A University which allows its graduates to be ignorant of Greek may perhaps be excused for expecting them to talk dog-Latin to nurses, &c.

I am, Sir, yours truly,

Nov. 17th, 1884. A LONDON TEACHER.

A Candidate of Twenty-Six Years' Service.—We have not inserted our correspondent's letter, because we understand that steps have already been taken to meet the difficulty of which he complains.

MEDICAL PRACTICE IN CANADA.

To the Editor of THE LANCET.

SIR,—If any of the readers of THE LANCET could give me any information in reference to practice in Canadian towns, I should esteem it a favour. I am desirous of learning the amount of fees usually paid, also whether it is difficult to obtain a practice, and the amount of the premium required in relation to the annual cash receipts.

I am, Sir, yours truly,

Nov. 12th, 1884. GENERAL PRACTITIONER.

Mr. J. H. G. Drummond.—The course of cholera is too uncertain to enable us to advise in individual cases; but so far as the intentions of the German Government have been disclosed, they are not in favour of such regulations as would prevent anyone in Germany from returning to this country, even if cholera did break out.

H. E. T.—We are unable to supply the information.

THE INCOME-TAX.

To the Editor of THE LANCET.

SIR,—It may be a help to your correspondent "In Morsu Diaboli," whose letter complaining of his assessment under the income-tax appeared in last Saturday's LANCET, to know that I found myself three weeks ago in the same plight that he complains of—that is to say, I received a notice of assessment to an amount that nearly equalled the total of my gross receipts, notwithstanding that I had duly returned some months previously a schedule showing that I was only liable for a sum somewhat less than half that now claimed. I at once wrote to the surveyor of taxes announcing my intention of appealing against the assessment. I also forwarded to him a statement of my expenses and receipts for the year, as requested on the notice. In reply, the surveyor wrote to say that if I would call upon him he could probably arrange matters without troubling me to appeal before the Commissioners. I called upon him, with the result that, after a slight contention as to the amount of one of the items I had deducted in the way of expenditure, he reduced the assessment to within a few pounds of the amount I had originally claimed to be assessed upon, and told me he should advise the Commissioners to assess me accordingly.

I may add that the following items are recognised as working expenses, and are allowed to be deducted from the gross receipts to obtain the amount of profits upon which the tax is payable—viz., half or third of amount of rent of dwelling house, if a portion of it be used for professional purposes; whole rent of branch surgery or consulting-rooms in another street or district, if used solely for professional purposes; rent of stables, &c., if rented separately from house; cost of drugs, instruments, and surgery requisites, and wages of surgery boy and assistant; keep and expense of horse or horses; coachman's wages. These items were furnished me by a surveyor of income-tax, and I have always found them allowed.

I am, Sir, yours faithfully,

Nov. 18th, 1884. L.R.C.P. LOND.

To the Editor of THE LANCET.

SIR,—Allow me to wish your income-tax correspondent well out of the "Morsus Diaboli." "Diaboli" is the correct name for Income-tax Commissioners. I have always fought them, and always successfully.

In appealing, a surgeon must give the details and amounts of his receipts for the three previous years on one side, and all his professional expenses for the same years on the other; deduct the one from the other and divide the remainder by three, and this will give the amount he will have to pay on; he can deduct life insurance premiums if he produce the receipts to be properly endorsed. Let him demand to be put on his oath as to the truth of his statements.

As to policy! Remember that the diaboli gossip with themselves and others; the diaboli do not regard their obligation to secrecy. Do the diaboli number any of his present or prospective patients among their number? If so, is it wise to say I am not so prosperous as you think? Many surgeons, I know, think it is not wise, and pay on their gross, and more than their gross, receipts, and think they are rewarded for their lie. Do the diaboli number any medical neighbours among them? If so, is it worth the money and deceit to hoodwink them? I am inclined to say, as a matter of policy, Do not follow my example, but act a lie and humbug the diaboli. I am, Sir, yours faithfully,

Framlingham, Nov., 1884. GEO. E. JEAFFRESON.

M.D.—No; penalty attaches to the assumption by an unregistered person of any name or title implying registration.

The "Bowman" Lecture

ON THE

RELATION OF CERTAIN DISEASES OF THE EYE TO GOUT.

Delivered before the Ophthalmological Society of the United Kingdom, Nov. 13th, 1884, by

JONATHAN HUTCHINSON, F.R.S.

(*Concluded from p. 903.*)

Insidious and Destructive Iritis from Inherited Gout.—I must now enter upon one of the most important topics of my lecture. It is the attempt to prove that there is a very peculiar form of destructive iritis, occurring for the most part in young persons, which stands in all cases in direct relation with the inheritance of a gouty constitution. It does not occur to those who themselves suffer from attacks of gout, but to their descendants.

It was in 1863 that I first saw, at Moorfields, a girl named M——. She was then about eighteen, tall, well-formed, and florid. She was too florid, and the circumscribed areas of colour in her cheeks varied in tint from bright-red to slightly livid, according to the coldness of the day. She was the subject at the same time of a most peculiar form of arthritis of the last joints of all her fingers, and of double iritis. Her right eye was lost and painful, and I accordingly excised it. Her left was saved only by repeated iridectomies and finally by extraction of the lens. After the last operation she continued for five years to enjoy good sight and was free from relapses. Her fingers also got well. At the age of twenty-six she became the subject of phthisis, and died, I believe, at about thirty. I showed this patient at the Hunterian Society, and drew attention to the unusual features of her disease. Some one present, looking at her hands, remarked, "Surely this is gout." I took the hint, inquired into her family history, and found that in all probability it was gout. Her father had suffered repeatedly from that malady in an unequivocal form, and he had tophi in his ears. I show you drawings of the state of the girl's fingers. In order to ascertain whether there were urate deposits in connexion with the swellings, I cut into one of the largest and obtained only a soft jelly-like substance. When after some years the swelling subsided the terminal joints were all left disorganised and the last phalanges were more or less displaced. There appeared reason to believe that a feeble state of the circulation combined in this case with the gout inheritance.

I have repeatedly mentioned M——'s case in public, and with it others which came under my notice subsequently, and I must content myself on the present occasion with a short summary of the facts. In 1872 I gave a lecture at Moorfields on this disease, and was able to cite four well-marked examples of it. In 1880 I gave at the London Hospital a second lecture, in which I adduced seven additional cases, making eleven in all. Of these eleven patients, four were females and seven males, but it happened that the most typical and severe forms of disease occurred in females, a fact which my subsequent experience has fully confirmed. In all cases both eyes ultimately suffered, but only in one were both affected simultaneously. In three instances last-joint arthritis—that is to say, destructive inflammation of the last joints of the digits—occurred. In all the cases vitreous opacities as well as iritic adhesions were developed. In most of the cases the eye which was last attacked suffered most, and a decided tendency was shown for the disease to come to an end as the patient advanced in life. In several cases the eye was saved by repeated iridectomies, and in one or two change of climate seemed to be very beneficial.

In all the cases but one the family history of gout was clear and strong, and in the exception the patient was the son of a brewer's man, and his father had died early, so that it was very possible that his proclivities had not declared themselves. In several of the cases the patient had been reduced almost to blindness. In three one eye had been excised, and in one both were quite lost. In all excepting two the disease had begun between puberty and the age of twenty-five; and it would appear to be a fact that the earlier it begins the more severe it is. Such, then, was the state of my facts in 1882, when I put my last lecture into print. I think you will allow that I was justified in avowing a strong belief that inherited gout was the real cause of this peculiar form of iritis.

That I may add a little more colour to my picture I will ask your permission to state briefly the facts of three cases which have come under my notice since the date referred to. They are all cases of great interest; and two of them illustrate a fact which I had previously only once or twice noticed—namely, that there is a tendency to the formation of cataract.

The last case which I have seen is that of a Miss D——, aged thirty, the daughter of a surgeon in the country. She was brought to me with the left eye quite destroyed and the right nearly so. In the left an opaque lens had undergone spontaneous absorption, and the iris was everywhere adherent to the opaque capsule. In the other the lens was half opaque, and the iris extensively adherent. I was told that I had myself seen this patient ten years before and had then recognised only commencing cataract in both. The patient's father, an intelligent medical man, was astonished when I told him that there had been extensive iritis, and assured me that his daughter had never had any attacks of inflammation. The patient herself said that she had never noticed more than that the eyes had sometimes been red and hot, and would prick a little. We have here, then, a good instance of the very insidious course of the disease. In the left eye there was no perception of light, and very probably the vitreous was affected. I found on inquiry that in Miss D——'s family there had been much gout. She herself appeared to be in good health.

Mrs. O—— is a young married lady who has borne three children, and during lactation in each instance suffered from a chronic form of almost painless iritis. Both pupils are almost excluded. Her father has suffered gout, and several other near relatives. She is of feeble circulation and liable to chilblains.

I have kept one of my best cases to the last. Miss L——, aged twenty-two, is the youngest of a family of eight, and was born after the death of her father, who had suffered much from "chalk gout." Her eldest brother has had both gout and rheumatism, and there is rheumatism also on her mother's side. Miss L—— began to suffer in her eyes at the age of twelve, and at first it was simply redness and irritability with "black specks," "balls," and mist. At the age of fourteen she had a severe attack in both and was several months under Mr. L——'s care, being almost blind. From this she recovered, but at eighteen a surgeon in Liverpool performed an iridectomy on the left on account of exclusion of the pupil. A little later Mr. C—— did an iridectomy in the right. Neither of these operations resulted in any improvement of sight. In 1880 a surgeon in Leeds removed a soft cataract. The eye was lost and Mr. C—— excised it a few months later. Miss L——'s present condition is that with the one remaining eye she can just puzzle out $\frac{1}{200}$. Could I possibly produce before you a more marked example of an insidious destructive disease, progressing in spite of the most highly skilled assistance to its melancholy end? Yet it is only a fair example of about half those included in my series.

Relapsing Cyclitis.—There is a peculiar form of chronic inflammation of certain parts of the eyeball which clinical observers have recognised under the name of "relaping cyclitis." It is a cyclo-kerato-iritis involving the ciliary region of the sclerotic, the adjacent part of the cornea, and the iris. Sometimes one of these structures suffers more than another, but usually all are involved. It seldom damages the pupil itself much, seldom invades the centre of the cornea, or only very late in the disease, and it does not show much tendency to involve the choroid or vitreous. It usually begins in one eye and only affects the other after a long interval, and to the last one usually suffers more severely than the other. It may begin in early life, but often does not do so till middle periods. When once it has begun it never wholly leaves its victim, but continues either to persist with slow chronicity, or recurs over and over again after intervals of health. It causes scars in the ciliary part of the cornea, thinning and discolouration of the ciliary region of the sclerotic, and ends either by inducing staphyloma or by making the whole cornea dull. It may occasionally become needful to excise the eyeball on account of the persisting irritability combined with great impairment. It affects, I think,

Digitized by Google

women more frequently than men. It is a very peculiar type of disease, and it would not be difficult to place side by side a group of examples of it all exactly alike. I know of no treatment short of a complete change of climate which does much to benefit it. In this respect it is much like the form of iritis which I have been striving to prove to be a direct result of inherited gout. Yet I am by no means in a position to produce before you respecting relapsing cyclitis such evidence in reference to its gout origin as that which we have been discussing. I dare not, indeed, do more than suggest that it is very probable that in some cases the constitutional cause of this destructive and persisting disease may be gout. I have found a gout history in some of my cases, but in others it has been absent. The last case which I have seen has been the one in which this suspicion was the strongest.

Miss D—— is the daughter of a medical friend. She is now forty, and she has suffered all her life from her eyes. She was treated when two years old by Mr. McMurdo for what was then called strumous ophthalmia, and which proved very intractable. Since then she has had numberless relapses, and in both eyes the cornea at its edges has become extensively opaque. Her left eye is the worse, and has recently been so troublesome that I was inclined to recommend its excision. It is by no means a blind eye, but the cornea is so hazy that it is of little use. Now, say that we have here a case in which strumous ophthalmia has persisted through life, let us ask what is the constitutional peculiarity which has conduced to this exceptional result. The lady has been well cared for all her life, she shows no other signs of struma, nor are such present in any of her relatives. Her father is a robust man. Mark that both eyes have suffered, and that in both it is the peripheral parts of the cornea which have been chiefly involved. Now, this lady's maternal grandfather and two of her maternal uncles suffered severely from gout, her mother had an attack in her great toe, and even she herself has on one occasion had an attack of it. This strong gout history is certainly by far the most definite fact which I can obtain as explaining the peculiarities of her eye disease.

Can Gout cause Neuritis?—Although from time to time strong suspicions have been expressed as to the occurrence of gouty affections of the nervous system, I believe the question has seldom been definitely put, "Does gout cause neuritis?" We know that gout can cause the tissue of a joint to inflame, and that œdematous effusion with cell proliferation, in fact, the ordinary phenomena of inflammation, are its results. I shall be much disappointed also if it is not regarded as proved that it can cause the tissue of the iris to inflame in a precisely similar manner and with like results. Can it attack any of the structures of which the nervous system is composed? Can it cause inflammation of ganglia, of nerve trunks or of their investments, or may it indeed attack the central organs? Without venturing to suggest that any of these occurrences are common, it is yet difficult to deny a possibility or even probability in exceptional cases. We can understand the influences that are likely to localise gout; its exciting causes may come into play far less frequently in reference to the nervous system than to the joints; or even to such an apparently exposed part of the organism as the eye. Still, if we admit that in the gouty condition inflammations may attack the cellular tissue in any part of the body, it is difficult to suppose that the cell elements which enter into the formation of nerve trunks, for instance, will always escape. I am glad to note in the progress of neuro-pathology of the last few years that there seems an increasing tendency to recognise the possibility that not a few nervous affections may be due, not to central disease, but to primary inflammation of the connecting trunks, or of the peripheral organs. We know for certain that chronic neuritis, probably beginning peripherally, is a part of leprosy. It is highly probable that it is often a part of syphilis, and quite possible that it occurs also in locomotor ataxy. How else explain many of the transitory forms of ptosis, &c., which occur in the two latter diseases?

Gouty Neuritis of the Optic Nerve.—The question which I now wish to put definitely is, Are there any cases of inflammation of the optic nerve, or of any of the motor nerve trunks of the eyeballs, the direct cause of which is the existence of a gouty constitution? The decision is of importance not only in reference to diseases of the eye, but because it would throw much light on certain other obscure affections met with in this disease. Is sciatica really a neuritis of the sciatic trunk or its sheath? Are any of the forms of gouty neuralgia really produced by gouty neuritis? If the optic nerve can inflame from gout, why not the pneumogastric or the phrenic? I am sorry to say that I have exceedingly little evidence to bring forward in answer to these important questions. I will mention briefly one or two facts which are suggestive, and which I hope will prove sufficiently so to induce a more careful investigation of the subject. In two or three cases I have attended young ladies, of families in which gout had been prevalent, who suffered from attacks of ptosis, with the other group of symptoms referable to paralysis of the third nerve, for which I could find no other more plausible explanation than that they were caused by gouty neuritis. In one of these the attacks were transitory and recurrent, several having occurred within a period of a few years. I must not venture to trouble you with details of these cases, but feel myself obliged to speak rather more at length concerning one in which the optic nerve itself was inflamed, there being, I think, fair reason to suspect that the cause was inherited gout. A young lady, aged sixteen, was brought to me from Ipswich, on account of blindness of one eye, in July, 1879. She had no other symptoms whatever, was florid, and appeared to be in good health. The ophthalmoscope showed nothing but what was quite normal, and had it not been that her pupil dilated more widely when the other was covered, I might have suspected that she was feigning. A week later the changes were conspicuous, the disc being much swollen and its margin concealed. Under treatment by mercury combined with quinine, in the course of a few weeks the attack had passed away, but the disc was left pale. Four years later I saw this patient again with similar symptoms in the other eye, and I was now told that she had several times suffered from transitory attacks which always occurred during spring. Her health remained perfect. There was a strong history of gout in the family, both her parents having suffered repeatedly. It seems to me not at all improbable that these recurrent attacks of transitory neuritis were really of a gouty type. In saying this I have regard to the entire absence of the more ordinary causes and concomitants of optic neuritis, to the recurrent nature of the affection, its want of symmetry, and the exceptionally strong family history, both parents and many other near relatives having suffered. I cannot call to mind any other case of recurring optic neuritis, with gout history, which I could at all fairly place side by side with this one. I have, however, several times seen optic neuritis occur in women who were of gouty family without any of its ordinary accompaniments, and clear away entirely under treatment. In none of the cases of which I am thinking did any recurrence take place, and in most of them both eyes were simultaneously attacked.

Other forms of Gouty Neuritis.—Before quite taking leave of this important question as to the possible occurrence of gouty neuritis, I must trouble you with yet one other case. A lady, of fifty-six, came under my observation in whom for several weeks the left facial nerve had been quite paralysed. I observed at once that she had had two large iridectomies done downwards and outwards, and on inquiry found that she was nearly blind. It was twenty-three years since she had first noticed cobwebs before her sight, and fifteen since she had last been able to read. The iridectomies had been done six years, with what object I do not know, for although she said that she had once had rheumatic inflammation of her eyes, there did not appear to be any adhesions. In each eye the lens was partially opaque, and in each there were extensive choroido-retinal changes with pigment deposits and waxy atrophy of the discs (a peculiar form of retinitis pigmentosa). Mrs. H—— told me that she had a sister who also had "amaurosis." I persuaded her to bring her sister, and may now state the family history which belongs to them both. One of their brothers suffers not unfrequently from attacks of unequivocal gout, and a sister is crippled by rheumatism, but their parents died aged, and are not known to have suffered. The elder of the sisters, aged sixty-nine, has herself had gout, and describes her great toes graphically as having been swollen and red like tomatoes. This sister, after her first confinement, aged twenty-seven, had an attack in her eyes which lasted several years, attended by great pain and intolerance of light. Her recovery from it was very gradual, but finally it was almost perfect, and I could now find no material changes. For several years she has been very deaf, and she has suffered severely from neuralgia and chronic arthritis of wrists and fingers. Once she was told, by Mr. Critchett, that she had

Digitized by Google

"gout in the eyes." The younger sister describes ten years ago an attack of shoulder neuralgia attended by torticollis, which kept her in bed six weeks and was accompanied by agonising pain, as if her arm were in the fire. She also has suffered most severely from neuralgia on many occasions.

Here, then, is a family so definitely gouty that a brother and sister have each had true gout, and several other sisters are crippled by rheumatism; one sister has become almost blind with neuro-retinitis, and has suffered from neuralgia, torticollis, facial paralysis, and an attack which was probably neuritis of the brachial plexus. Another sister is deaf, has been all her life liable to neuralgia, had a several years' attack of pain in her eyes which was called "amaurosis," and in later life one which was named "gout in the eye." It seems highly probable that we have here an instance of gout affecting, at different periods of life in each sister, different parts of the nervous system, and attended by true neuritis of various nerve structures.

Glaucoma in Relation with Gout.—I had intended to have said a good deal as to the nature of glaucoma, and the evidence as to its connexion with gout. The subject is, however, too important to be discussed hurriedly, and I have not time to attempt to do it justice. I must therefore content myself with the mere expression of opinion that in the production of this extraordinary disease a gouty tendency often takes a large share. More particularly would I suggest this in the exceptional cases in which glaucoma shows itself in early life; and I could, if time permitted, bring before you some important cases illustrating this point.

Retinitis Hæmorrhagica and its connexion with Gout.—There is yet another definite and well-characterised affection of the eye which claims conspicuous mention in connexion with our subject. Retinitis hæmorrhagica is very rarely indeed seen excepting in those who are themselves gouty. It is a disease of middle life or of advancing years, and in its more typical forms is never seen in the young. It seldom happens to both eyes at once. It is attended by great swelling of the disc and adjacent parts of retina and by such turgidity of the central vein that I was at one time tempted to believe that it depended primarily upon thrombotic phlebitis of that vessel. It is possible, however, that such is not its true pathology, and that the venous distension and stasis, perhaps in some instances thrombosis, are really secondary to the neuritis. If this be the fact, and neuro-retinitis be the primary condition, then we have in retinitis hæmorrhagica an instance in proof that acquired or humoral gout may become the cause of neuritis. It is not, I think, ever seen in association with the inheritance only of a gouty constitution, but is found with lithæmia in free livers who have usually experienced unequivocal attacks. The case which Jaeger took for his beautiful plate in illustration of the disease was that of a tavern keeper of plethoric habit and liberated appearance. Nothing is said as to gout, but it is fair in such a man to assume that there was a tendency to it. In order to determine statistically, as far as practicable, the association of retinitis hæmorrhagica with gout, I have tabulated twenty-four cases, with the exception of the one of Jaeger's all from my own note-books. In twelve of these, exactly one-half, the patient had suffered definite attacks of gout, and in five others there was strong presumptive evidence of a gouty constitution. In seven there was no proof of gout. This last group comprises two in which diabetes was present, one in which albuminuria existed, and two in which the retinitis was not very well characterised as of the hæmorrhagic group. If I had kept more closely to the type of cases illustrated by Jaeger's portrait, I should have been able to make yet stronger statements as to the almost invariable association of the disease with gout. It may be of interest to state a few other facts deduced from my table. Thirteen of the patients were men and eleven women. The youngest was forty-five. In seventeen cases only one eye was affected, and in seven both. In some cases there were hæmorrhages only, with little, if any, evidence of neuro-retinitis.

Summary.—I must now bring my lecture to a close, and in doing so may, I think, venture to assume that it has been shown to be probable that there are many different forms of inflammation of the eye, or of parts of it, which are in connexion with gout. Some of these are very peculiar and specialised types of disease, and have already been accorded distinctive clinical names; others quite as distinct are not as yet so well known, and of others we may say that they are to be distinguished from other inflammations of the same structures not so much by their features as by their cause. Of all we may assert that they are infrequent; some, if we confine ourselves to well-marked types, are distinctly rare. We have divided these different affections into two groups: (1) those who go with acquired, humoral or renal gout, and (2) those which depend upon the inheritance of structures damaged, or an any rates specialised, by gout in predecessors. It is needless to repeat that in almost all cases of acquired gout there is inheritance also, and that in many in which the disease is chiefly caused by inheritance some modification and increase may have been derived from personal habits. Still, the difference between the two classes of affections is very marked. In the one attacks of a transitory nature are the rule, and these attacks are often acute and attended by much pain. In the second group, although a tendency to temporary recovery and recurrence is often observed, yet there is a great proneness to chronicity and persistence. The invasion is often insidious, but the disease is usually in the end destructive. In the former group we have placed hot eye, sclerotitis, recurrent iritis, and retinitis hæmorrhagica. All these are diseases of adult life. In the second group we have insidious disorganising iritis, relapsing cyclitis, certain forms of soft cataract, and perhaps some of primary optic neuritis. Not only are there clearly marked clinical differences between the two classes of affections, but the difference in treatment is equally marked. In the first the well-known measures against gout must be taken—a restricted regimen, alkalies, colchicum, and aconite, and liberal counter-irritation. In the second we must use tonics, and although counter-irritants are here also often valuable, we cannot trust to any measure as really curative short of complete change of climate.

On the Proofs of Gout.—It may be, perhaps, convenient to say a few words as to the kind of evidence which justifies a diagnosis of gout as the cause of any particular disease of the eye. In the case of humoral or acquired gout there ought to be the history of one or more definite attacks of joint inflammation usually of an acute character, and attended by redness and œdema, and following by peeling; usually the great toe will have been the joint affected. Such patients will often state that they are very susceptible to the influence of beer and wine, and that malt liquor and some wines almost always cause indigestion, and make the urine muddy. These dietetic disturbances, to which as a test of gout attention was, I think, first claimed by Sir James Paget, are very important and valuable. If tophi are present in the ears or elsewhere they are of course conclusive. In a few cases we are justified in assuming the existence of humoral gout, although no paroxysm has ever occurred. If the dyspepsia be there, if the joints ache and prick after beer or wine, and if there be gout in relatives, we may confidently believe that it is present, although not yet declared. As regards the inherited form, we may take it as highly probable whenever parents or grandparents, or any one of them, are known to have suffered definitely. If even uncles, aunts, brothers, or sisters, or cousins have suffered from true gout in early life, the belief that a family taint exists becomes very probable. The evidence must always be carefully sifted. It will not do to take the statement of the patient without first carefully informing him as to the scope of the inquiry. Patients will often confess to gout who do not know what the word means, and a far more numerous class will hastily deny its history, although the facts, when correctly obtained, may be most conclusive. If, however, proper care be taken, and the patient, after being instructed, be allowed time for consideration—above all, if the inquiry be repeated after an interval, or if several relatives be interrogated, then I believe that in most cases truthful data will be obtainable.

It may be inquired as to the value of certain affections which may be considered to belong both to rheumatism and gout, as symptoms of the latter. Permit me very briefly to repeat my creed. I believe that the subjects of gonorrhœal rheumatism are in a very large majority of instances the inheritors of a gouty constitution, and that all the conditions usually classed as rheumatic gout are really, in most instances, dependent in a large degree upon like inheritance. Thus, if a patient has had sciatica or lumbago, if he shows nodi digitorum (osseous, not tophi), if he has suffered from chronic rheumatism affecting the smaller joints, I should think it fair to allow considerable weight to these facts as pointing to a taint of gout. Even the strictly rheumatic disorders, acute rheumatism itself, if it happens to the relatives of those who have had gout, lend support to the

Digitized by Google

theory of family tendency to gout. It is an observation as old as the days of Heberden, and confirmed I am sure by daily experience, that the children of the gouty are more liable than others to attacks of rheumatic fever. In this we see another proof of the inheritance of structural proclivities, rather, I think, than of blood disorder or tendency to it.

Conclusion.—And now, gentlemen, as my last word, I do not know whether I have to defend myself in the eyes of any of you from the charge of "seeing gout in everything." I am well aware that this diagnosis is a very easy one, and seductively ready at hand for the idle prescriber. I submit, however, that it has not been exactly in that temper that I have brought before you the statements which I have made this evening. My desire has been to state the issues explicitly, and to keep close to facts. Where statistics were admissible and obtainable I have had recourse to them. I may assert that I have said nothing but what has been based not only upon clinical observation, but upon clinical note-taking, and the subsequent collation of cases. Nor, I contend, have I made any very sweeping statements. So far from my having exceeded the truth, my conviction is that when our clinical pathology shall be more advanced, and diseases more minutely classified, we shall in all probability recognise as gouty yet other maladies, and perhaps not a few beyond what I have claimed. It is a subject upon which scepticism is as irrational as credulity. That the gouty constitution exists, and is very common in our English population, that it is potent in the production of disease, and that it is remarkably hereditary, are facts which no one will doubt. In relation to the multiform diseases of the eye it must have a domain, and that an important one. To discover some of the extensions and limits of that domain has been the object of my best endeavours to-night.

SYPHILIS IN DENMARK.

By HENRY LEE, F.R.C.S.,
CONSULTING SURGEON TO ST. GEORGE'S HOSPITAL.

DR. GIERSING has lately published at Copenhagen[1] a most elaborate and exhaustive statistical account of venereal diseases in Denmark. The tables and figures which he has given are taken from the reports to the Royal College of Health which all the medical men in private practice as well as those holding official appointments are obliged to furnish. During the last fifty years Copenhagen has been under very strict police regulation, and since 1854 laws which correspond with our late Contagious Diseases Acts have been rigidly enforced. During the ten years[2] comprising a record of 55,923 cases, there was an increase of blennorrhagia of 37 per cent., a diminution of the local venereal sore of 28 per cent., and an increase of syphilis of 1 per cent. In Copenhagen the number of women known to be diseased had increased from 1358 in the year 1881 to 2352 in the year 1883. In thirteen years, while the population had increased 43 per cent., venereal diseases had increased nearly 100 per cent. The system of police supervision has therefore failed in Copenhagen. In six other towns under police regulation (protected), the results are much more satisfactory. All these with one exception were seaport towns with garrisons. During the same ten years in them blennorrhagia had scarcely increased, the local venereal sore had diminished 51 per cent., and syphilis 60 per cent. Great fluctuations, however, occurred during this period. In three of these towns police regulation has been withdrawn since 1880, probably for the following reasons: In the towns not protected, containing 197,000 inhabitants, blennorrhagia had very slightly increased, the local venereal sore had decreased 43 per cent., and syphilis 35 per cent. during the same time. In proportion to the population the cases of syphilis were 11 per thousand in the protected and 9 per thousand in the unprotected towns, so that, although the diminution of disease in the protected garrison towns is very satisfactory, yet the amount of disease in them is still considerably greater than in the unprotected towns. In the country, out of a population of 1,141,000, there were 11,154 cases of venereal disease during the ten years ending 1880. At this time blennorrhagia had decreased 26 per cent., the local venereal sore 42 per cent., and syphilis 59 per cent. With the exception of the year 1872, there was a gradual decrease of venereal disease during the whole of this period. Altogether there was a decrease of 49 per cent. In the year 1871 there was an increase of syphilis, but since that time it had progressively diminished in nine years 62 per cent. This was without any police supervision. In Copenhagen, during the eight years 1874-81 inclusive, syphilis had increased in the navy 163 per cent., and in the army 36 per cent.

It may be very interesting to compare these statistics with the returns given by our medical officers in the army as set forth in the minutes of evidence taken before the Select Committee of the House of Commons on the Contagious Diseases Acts printed in 1881. Unfortunately, no accurate account either in Denmark or with regard to the English army can be obtained of the relative number of infecting and non-infecting sores. In fact this is not attempted in the army returns. The only way in which any definite conclusions can be arrived at with regard to this subject is to take the number of cases of secondary syphilis which are easily recognised in any particular districts, or under any particular regulations, and to compare them with others. The number of cases of secondary syphilis, treatment and other circumstances being the same, will then give the comparative numbers of cases of primary syphilis.

Now, on comparing the figures submitted to the Select Committee for the year 1866 (before the late Contagious Diseases Act was passed) with those for 1878, secondary affections appear to have increased by 2 per 1000 in the Home Army,[3] and therefore we must conclude that primary syphilis had also increased during that period. From the year 1859 to 1866 inclusive, secondary syphilis diminished in the army from 35·86 to 24·77 per 1000 men. From 1867, when the Contagious Diseases Acts came into operation, to the year 1876, the ratio had increased to 27·4 per 1000. Thus the figures, both with regard to the general population in Denmark and to the army in England, tend to show, as far as they go, that the unprotected districts are rather better off than the protected, as far as true syphilis is concerned.

ON CHOREA IN THE AGED.

By ROBT. SAUNDBY, M.D.EDIN., M.R.C.P.,
ASSISTANT PHYSICIAN TO THE GENERAL HOSPITAL, BIRMINGHAM.

ALTHOUGH the occurrence of chorea in the aged was noticed by Graves, we are indebted to Professor Charcot for awakening general attention to the subject. During the last six years I have met with three cases, two of them hospital out-patients, the other was seen in consultation with Mr. J. W. Taylor of Camp-hill.

CASE 1.—This was a man of intemperate habits, about fifty years of age, suffering from advanced disease of the aortic valves. The chorea affected the left side, and chiefly the left upper extremity. The movements were not without intermission, and were to some extent under voluntary control. They consisted of rapid flexion and rotation of the left arm, which was slipped behind his back. This movement was so constant that he was wearing a smooth patch on his coat over the left scapular region where his hand rubbed each time. There was not the slightest appearance of dementia, though there was marked impairment of general health.

Dr. F. Leslie Phillips, who has succeeded Mr. J. W. Taylor, has kindly furnished me with the following account of the present condition of this patient.

Mr. W——, aged sixty-six, has never had acute rheumatism; he does not attribute his illness to any emotional cause, but he had had worry in his business for the previous twelve months. At the present time he feels weak, but can walk half a mile; he has occasional gouty pains in his joints and in the muscles of his legs. The choreiform movements of the left side have much abated, but there still remain some nervous hasty involuntary movements, especially of the hand and wrist. The grasp of the left hand is distinctly weak, but he has no recollection of anything like a stroke. He has a double aortic murmur, and "a mitral systolic murmur also; there is no sign of cardiac dilatation," and no albuminuria.

Digitized by Google

CASE 2.—Dr. Russell[1] has published a short account of a case formerly under my care. This patient was a man aged sixty-eight, who had been ill for eighteen months. He had no cardiac disease, and there was no history of rheumatism. He could assign no cause for his illness. His urine contained a trace of albumen with granular and blood casts, blood-corpuscles, and epithelium. He presented no signs of dementia.

CASE 3.—My third case is that of an old man aged eighty-seven. He is fairly well nourished but anæmic. He has enjoyed good health, and the only illness he can call to mind is an attack of congestion of the lungs four years ago, since which he has been liable to bronchitis, for which he applied for advice. There is no obvious dementia, he answers questions rationally and correctly, but is a little deaf. The tongue is protruded perfectly well. There is no cardiac murmur. The choreic movements are not constant, and chiefly affect the arms, though the head and legs are not free. The muscles which appear to act most violently are those connecting the trunk with the upper extremity, especially the scapular muscles, which jerk his arms till his back aches. The muscular movements are so violent as to throw him about in his chair, if he is standing to make it difficult for him to remain erect, and when sleeping to awaken him. At the present time (June 25th, 1884) the disease has lasted about five weeks. His urine contains a trace of albumen; he has never had acute rheumatism, and has no evidence of valvular disease of the heart, though there is probably some dilatation with atheromatous degeneration of the arteries. He has an enlargement of the head of the first and second metacarpal bones of the right hand, and has suffered from "rheumatism" in all his joints, but never was laid up with it. He attributes this illness to getting wet, which he was very liable to in his work as a gardener. On inquiry, he does not admit that he has had any trouble, and seems of a cheerful disposition. He has never had anything like a fit, or been paralysed. He says he has always been temperate, and I have no reason to doubt his statement. The twitching first came on in his right shoulder. He can pick up a pin fairly well, and says he has no difficulty in buttoning his clothes.

CASE 4.—Dr. Russell[2] has also related the case of a lady, aged seventy-seven, who recovered after an illness of about three months. In this patient the chorea was mainly left-sided. There was no dementia; the heart was normal, and she had never suffered from rheumatism or previously from chorea. The treatment employed was the sulphate of zinc.

CASE 5.—Mr. C. J. Davis[3] has reported a case in a man, aged seventy-nine. The chorea was confined to the left upper extremity and the left side of the face. The patient was demented. There was no cardiac murmur or history of rheumatism. There was a trace of albumen in the urine. He died while under observation after the chorea had lasted a month, but no autopsy was made.

CASES 6 and 7.—Dr. Wharton Sinkler[4] believes this disease is rare, but is mistaken for senile trembling or paralysis agitans. He gives two well-marked cases in a male and female aged eighty-six and eighty-two respectively. One recovered in a few months, the other remained in the same state after two years and a half. Organic heart disease was present in both. There was no dementia in either case.

CASE 8.—Dr. M. Bacon[5] has published a case of chorea in a female suffering from chronic mania and the inmate of an asylum. The disease lasted four years—that is, until her death at the age of sixty-one.

CASES 9 and 10.—Dr. Graves[6] mentions two cases: one an apothecary in Dublin, aged seventy; and another which had been communicated to him by Dr. Patton of Tandragee. Of the former case he gives no details, except that "it was very severe and lasted many months." Of the second, he tells us that it had continued three years at the time of his report; that the patient was a woman aged fifty, who had had family troubles; that the attacks were intermittent, but, when present, did not leave her, even during sleep. Fatigue, anxiety, and the "changing of the moon" were said to aggravate her attacks.

CASES 11 and 12.—Charcot,[7] in his well-known lecture, points out that this condition differs essentially from the senile trembling to which the name "senile chorea" is sometimes improperly given. In the latter the movements are simply oscillatory, and have none of the gesticulatory character of choreic movements; usually, too, the trembling is limited to the head. Both his patients were more or less demented. He regards the chorea as due to emotional causes, and not associated with rheumatism or heart disease. He thinks it is incurable, but does not usually endanger life. Of his two cases one had existed twelve and the other eleven years, both patients being the same age, seventy-one.

To some extent Professor Charcot's views are open to modification in the light of our more extended knowledge of the subject. For example, we must abandon the belief that this disease is always associated with dementia. It is also very dubious if we can attach any high degree of importance to emotional causes in the origin of this affection, while the recovery of Dr. Russell's patient and the great improvement which has taken place in my first case make the prognosis much less absolutely unfavourable than Charcot taught. Its association with heart disease in both of Dr. Sinkler's cases, and in one of mine, must also be allowed to qualify Charcot's statement that no such relation appears to exist, though it may well be that the association has no special significance. Yet from what I have seen of this disease, and from the extreme probability that advanced degeneration of the vascular system was present in all my cases, I am inclined to believe that the pathology of this affection will be found to be some actual structural change, such as small hæmorrhages in the corpus striatum, and that it is not merely a functional disarrangement. In the absence of any post-mortem evidence whatever, such an opinion is of course wholly speculative.

The diagnosis presents no difficulty to any one who is aware of the existence of this form of chorea, the character of the movements is quite typical, and if it is ever confounded with senile trembling, it must be from ignorance of the fact that chorea does occur in advanced life, and consequent unwillingness to accept a view which is thought to be unsupported by authority. My third patient suffered so intermittingly that at his first visit I observed nothing, and was told nothing to direct my attention to anything but the state of the chest, but on his next appearance the movements at once attracted my attention. In Mr. Taylor's patient I noticed a similar indifference on the part of the patient to the movements, which he appeared to regard rather as an awkward habit than as anything for which he needed medical advice.

I regard the disease as rare. The cases seen by Dr. Russell and myself are all I have heard of in this town, and from inquiries I have lately made, there is no case at our workhouse infirmary whose chronic nervous affections of all kinds are to be found. With respect to treatment, I have not much to say that is of value. I have found the bromide of potassium of some use, and in Dr. Russell's case, which recovered, sulphate of zinc was used. In all of my cases the general health has been very bad. For such feeble old people cod-liver oil is one of the best remedies.

Birmingham.

TREATMENT OF PERFORATING ULCER OF THE FOOT.

BY FREDERICK TREVES, F.R.C.S.,
SURGEON TO AND LECTURER ON ANATOMY AT THE LONDON HOSPITAL.

THE so-called perforating ulcer of the foot, when it appears in association with locomotor ataxy, or the conditions somewhat vaguely known as sclerosis or tabes, is the outcome of certain purely local causes acting upon a part whose condition has been injuriously influenced by a central nerve disturbance. There are reasons for believing that the nutrition of certain parts becomes obscurely perverted in the course of the nerve malady, and that the foot affords one example of such perversion. Moreover, the sensation in the integument of the sole commonly becomes dulled; and if to these conditions be added the effects of pressure upon the skin, it would appear that the chief factors in the production of perforating ulcer are present. Of these the disturbance of nutrition is probably the most important; for the pecu-

Digitized by Google

liar ulcer may be seen upon the feet of patients who, although they present certain of the symptoms of locomotor ataxy, do not yet experience any perverted sensation in the limb. It would seem, moreover, that there is nothing peculiar in the pressure to which the part is subjected. It is the pressure incident to standing and movement. The sore is often met with quite early in the course of the cord affection, and at a time when the patient's gait is steady and regular, and when he walks like the normal man.

The clinical history of the ulcer is briefly this. At a spot upon the sole of the foot upon which pressure bears a corn appears. This spot is very commonly over the metatarso-phalangeal joint of the great toe, or over the corresponding joint of the little or on the pulp of the great toe. The corn increases, and, from the pressure that it exercises upon the soft parts beneath it, some inflammation of an insidious type follows. Suppuration then appears beneath the corn, and, spreading in the direction of the least resistance, advances into the soft parts of the sole, moving towards the bone. It may be that the column of soft parts compressed between the corn and the bone beneath which it lies may perish almost *en masse*, as would appear to be the case with the tissues in the acute bedsore of spinal origin. Be this as it may, this at least is evident, that when at last the pus finds an escape through the thickened skin about the corn a sinus is revealed that will be found to extend already to the bone. The patient continues to walk upon the foot, and around the orifice of the sinus or the margins of the ulcer the epithelium continues to heap itself up. This thickening of the skin is always considerable. The sore appears to be set upon a mound of hardened, thickened integument; and it thus happens that the depth of the ulcer or the length of the sinus is greatly increased. Bone may be lying bare at the bottom of the sinus. In the most chronic cases the so-called perforating ulcer becomes simply a persistent intractable sinus, surrounded by an areola of greatly thickened skin, and attended by a varying amount of pain. In such a condition it may prove a great hindrance to locomotion, and be a cause of lameness in cases where an ataxic gait has not yet developed. In other instances the pressure exercised by the thickened skin about the sinus tends to encourage an increase in the sore, or the parts may become the seat of a slough comparable with that met with in bedsore. The progress of the case will vary with the advancement of the nerve symptoms and with the ability of the patient to walk. The ulcer probably causes the most serious inconvenience in the most chronic cases. In such cases it is a source of pain, it impedes locomotion, it interferes with the pursuit of any occupation involving much standing, and is often the only, or at least the main, cause of the patient's lameness. In these instances the ulcer assumes for a while an importance in excess of that attending the nervous phenomena, and for months or years in the course of a given case it may be the only symptom that appears to clamour for treatment. It now remains to consider upon what lines such treatment should be directed.

In the first place, it may be said that these ulcers, except when of unusually severe character, may be healed without other especial treatment than that of absolute rest. The rest, however, must be very prolonged, and will in any case probably extend into several months. It unfortunately happens, moreover, that the ulcer so cured will reappear when the patient discontinues the treatment and once more uses the foot. It would seem to be distinctly unadvisable to enforce prolonged rest upon a patient whose general health is not seriously impaired, especially when such action can afford but temporary relief to the trouble for which he seeks assistance. Many individuals suffering from perforating ulcer are still able to follow an employment, and but for the ulcer many could follow very active and even arduous occupations. Messrs. Savory and Butlin in their valuable monograph upon this affection in the Transactions of the Royal Medical and Chirurgical Society[1] fully recognise this difficulty, and suggest that the patient should use an artificial "bucket leg," so that the foot may be kept from the ground without absolute confinement being necessary. This course, if adopted by patients of the humbler classes, may be a very grave inconvenience, and would, moreover, in those who are actually ataxic, add to the difficulty of progression. Failing relief by means of rest, the advice most generally given by surgeons is that the part of the foot involved in the sore should be forthwith amputated. Mr. Erichsen, in his last edition (1884) of his "Surgery" merely observes, "the treatment consists in amputation of the affected part." Mr. Bryant, in the fourth edition of his manual, endorses Mr. Hancock's conclusions upon this subject: "When once perforating ulcer of the sole of the foot is established and recognised, it is better at once to remove the whole of the metatarsal bones either by Chopart's, Syme's, or Pirogoff's amputation." With regard to this treatment there is, in addition to any objection that may attend amputation generally, the grave disadvantage that after the part has been removed the sore will return in the stump. The conditions that produced the ulcer in the foot are still operating, and by like agencies cause the re-appearance of the disease after the amputation. Messrs. Savory and Butlin well express the therapeutic position of this measure in the following words:—"With regard to treatment, it cannot be said that by any means at present known there is a fair prospect of permanent cure. In too many cases after operation, whether excision of the soft structures affected or of the diseased bone, or amputation of a toe or of a portion of the foot, the disease has gradually returned in some neighbouring parts, so that the extreme measure is at best a doubtful one."
